Comprehensive Wastewater Management Plan / Single Environmental Impact Report

Volume 2: Appendices

November, 2020

LIST OF APPENDICES

Appendix A: Cape Cod Commission (CCC) 208 Plan

Appendix B: CCC Barnstable Harbor Watershed Report

Appendix C: CCC Centerville River Watershed Report

Appendix D: CCC Lewis Bay Watershed Report

Appendix E: CCC Three Bays Watershed Report

Appendix F: CCC Popponesset Bay Watershed Report

Appendix G: CCC Rushy Marsh Watershed Report

Appendix H: Injection Well Pilot Testing Evaluation; March 2003

Appendix I: Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension Preliminary Design Report; September 2003

Appendix J: Preliminary Evaluation of the Cape Cod Community College for Treated Water Recharge; November 2003

Appendix K: Preliminary Evaluation of the Lorusso Property for Treated Water Recharge; November 2003

Appendix L: Effluent Mitigation Investigation Project – Candidate Site Evaluation and Comparison; December 2003

Appendix M: Preliminary Evaluation of the McManus Property for Treated Water Recharge; May 2004

Appendix N: Preliminary Evaluation of the Barnstable Municipal Airport for Treated Water Recharge; May 2004

Appendix O: Benchmark Evaluation to Investigate Groundwater Mounding Downgradient of the Hyannis WPCF; February 2005

Appendix P: Effluent Disposal and Reuse Planning Guidance Document and Case Study Report; February 2005

Appendix Q: Infiltration Loading Tests, McManus Site; October 2005

Appendix R: Needs Assessment Report Comprehensive Wastewater Management Planning (CWMP) Project Town of Barnstable, MA; May 2011

Appendix 1-1 of Appendix R: Final Wastewater Facilities Plan and Final Environmental Impact Report for the Town of Barnstable; March 2007

Appendix S: 2017 PALS STUDY

Appendix T: MEP Technical Report for Popponesset Bay; MEP, September 2004.

Appendix U: MassDEP TMDL Report for Popponesset Bay; MassDEP, April 10, 2006.

Appendix V: MEP Technical Report for Rushy Marsh; MEP, April 2006

Appendix W: MEP Technical Report for Three Bay System; MEP, April 2006.

Appendix X: MassDEP TMDL Report for Three Bay System; MassDEP, September 7, 2007.

Appendix Y: MEP Technical Report for Centerville River System; MEP, November 2006.

LIST OF APPENDICES CONTIUNED

Appendix Z: MassDEP TMDL Report for Centerville River System; MassDEP, January 29, 2008.

Appendix AA: MEP Technical Report for Lewis Bay (and Halls Creek); MEP, December 2008.

Appendix BB: MassDEP TMDL Report for Lewis Bay System and Halls Creek, March 2015

Appendix CC: MEP Draft Technical Report for Barnstable Harbor, June 2017

Appendix DD: Groundwater Protection Overlay Districts (Barnstable Town Code 240-35)

Appendix EE: Interim Saltwater Estuary Regulation (Barnstable Town Code 360-45)

Appendix FF: 2016 Final Barnstable SewerCAD Tech Memo

Appendix GG: BWPCD Groundwater Discharge Permit

Appendix HH: Marstons Mills Wastewater Treatment Facility Groundwater Discharge Permit

Appendix II: Popponesset Bay Watershed Inter-municipal Agreement

Appendix JJ: Feasibility Analysis of Shared Wastewater Treatment and Effluent Recharge between Barnstable, MA and Yarmouth, MA

Appendix KK: JBCC Wastewater Evaluation, December 2014

Appendix LL: JBCC Shared Wastewater Management Study, 2017

Appendix MM: Conveyance Alternative Analysis

Appendix NN: JBCC Section 2 Updates

Appendix OO: Fresh Pond Restoration and Management Benthic Nutrient Flux of Mill Pond

Appendix PP: Fertilizer Nitrogen and Phosphorous Control Ordinance (Barnstable Town Code Chapter 78)

Appendix QQ: SMAST Summary of Barnstable Watershed Loading and Modeling Update, December 2019

Appendix RR: Action Plan for the Barnstable Ponds

Appendix SS: 2020 Wastewater Plan MEP Scenarios: Additional 3 Bays Sewering and Barnstable Great Marshes Impact

Appendix TT: Barnstable CWMP - Climate Adaptation and Resiliency Approach

Appendix UU: Barnstable CWMP – Preliminary GHG Emissions Review

Appendix VV: Conceptual Sewer Expansion – Restricted Land Map

Appendix WW: Conceptual Sewer Expansion – Regulatory Overlays

Appendix XX: CDM Smith Effluent Disposal Capacity Study

Appendix YY: Effluent Outfall Preliminary Feasibility Review

Appendix ZZ: Barnstable CWMP EENF Form

Appendix AAA: Secretary Certificate, April 3, 2020

ACKNOWLEDGMENTS

Completion of the Cape Cod Water Quality Management Plan Update would not have been possible without the dedicated time and energy of the following agencies and organizations:

United States Environmental Protection Agency Region 1

Massachusetts Department of Environmental Protection

Massachusetts Secretary of Energy and Environmental Affairs

Cape Cod and Islands Legislative Delegation

Massachusetts Clean Water Trust

Cape Cod Commission

Cape Cod Water Protection Collaborative

Barnstable County Department of Health and the Environment

Cape Cod Chamber of Commerce

Association to Preserve Cape Cod

Working Group Stakeholders

Plan Summary

Updating Section 208

This report documents an update to the 1978 Section 208 Plan for Cape Cod. In a January 30, 2013 letter, the Massachusetts Department of Environmental Protection directed the Cape Cod Commission to prepare an update to the 1978 Water Quality Management Plan for Cape Cod to address the degradation of Cape Cod's water resources from excessive nutrients, primarily nitrogen.

In 1978 the plan identified increasing residential densities and a three-fold summer population influx as the cause of isolated water quality and wastewater management problems. It anticipated that future growth threatened to cause more serious groundwater contamination and increased eutrophication in surface waters. Today, the region is facing the impacts of that growth and working to maintain the environmental integrity that is so vital to the economy of this special place.

Cape Cod has a water problem. The saltwater border that has defined our peninsula is being poisoned by nitrogen. The rapid decrease in the water quality of Cape Cod's marine ecosystems is plain to see. The problem is nitrogen and the largest controllable source is the septic systems used every day.

For over a decade the Massachusetts Department of Environmental Protection (MassDEP), the Cape Cod Commission (Commission) and the Massachusetts Estuaries Project (MEP) at the University of Massachusetts-Dartmouth have worked with the 15 Towns on Cape Cod to research and diagnose the problem. In January 2013 the Commonwealth of Massachusetts used the Federal Clean Water Act and directed the Commission to update the 1978 Section 208 plan for Cape Cod. The designation and direction were accompanied by a short time-frame and a focus on nitrogen.

Massachusetts saw the opportunity to use this approach on Cape Cod as a way to combine the independent efforts underway and develop strategies and investigate new technologies and policies to address the looming environmental and economic crises.

The Commission worked with hundreds of people across the region and filed a draft Section 208 Plan Update in June 2014. MassDEP and US EPA reviewed the draft and it was offered for an extended period of public comment in August that closed in November 2014.

THE PROBLEM

Nitrogen is impacting coastal water quality. About 80% of the nitrogen that enters Cape Cod's watersheds is from septic systems. The conditions it creates destroy animal habitat and result in frequent violations of water quality standards indicated in part by fish kills and diminished shellfisheries. The Cape Cod seasonal economy relies on the water that surrounds the region and the degraded water quality is negatively impacting important economic drivers including coastal property values. Restored coastal water quality is an environmental and economic imperative; however, the current planning and regulatory environment makes it difficult for communities to identify cost effective, implementable solutions.

Plan Summary

TOTAL MAXIMUM DAILY LOADS

HOW MUCH IS TOO MUCH?

A Total Maximum Daily Load (TMDL) is a calculation of the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. TMDL's are technical planning documents and are not, in and of themselves, enforceable documents requiring compliance. Federal, state and local authorities implement TMDL's by incorporating the limit as part of other enforceable legal instruments, such as Massachusetts groundwater discharge permits in the case of some nonpoint sources of pollution or National Pollutant Discharge Elimination System (NPDES) permits in the case of NPDES-regulated point source discharges. TMDL's are useful in quantifying goals for reducing or eliminating pollutants that degrade conditions in a waterbody measured qualitatively as fishable and swimmable by the federal Clean Water Act.

As detailed below, the Commonwealth and the University of Massachusetts School for Marine Science and Technology (SMAST) established the Massachusetts Estuaries Project (MEP) which has been working to determine the maximum amount of nitrogen Cape Cod marine ecosystems can accept without becoming eutrophic.

THE COST OF DOING NOTHING

Cape Cod's water resources drive the regional economy. They attract visitors in the summer months and make the Cape a desirable place to live for year-round and seasonal residents. Continuing and increasing nitrogen loading of Cape Cod's embayment watersheds will further degrade coastal water quality, adversely impacting environmental, economic, and societal norms. The economic impact of doing nothing to restore coastal water quality will be significant, affecting every homeowner in the region.

3VS

The Cape Cod Triple Value Simulation (3VS) model is one resource being developed to consider the broader environmental and societal costs of environmental degradation. As a sustainability assessment tool, the 3VS model applies systems thinking to the problem of nitrogen pollution in Cape Cod embayments. Phase 1 of the model will estimate the potential social, economic and environmental costs of not taking action to mitigate projected increases in nitrogen loadings to Cape Cod embayments. Phase 2 of the model will include a comparison of policy intervention scenarios to evaluate direct and indirect costs and benefits of different potential actions to reduce nitrogen loadings. The 3VS model incorporates data sets from around the country to estimate costs associated with inaction.

Case Study: Three Bays

THREE BAYS: ESTIMATED IMPACT OF NITROGEN ON PROPERTY VALUES

A study evaluating home prices in the Three Bays area in the Town of Barnstable was conducted to test the hypothesis that water quality degradation resulting from nitrogen pollution impacts single-family home sale prices negatively. Single-family properties within 1,000m or about 10 minutes walking distance from the waterfront comprise the study area. The model estimates the impact of water quality – nitrogen levels – on home sale prices, controlling for property attributes, macroeconomic influences, proximity to public beaches, distance to water. The time period of the analysis is between 2005 and 2013.

Initial findings demonstrate a 1% increase in nitrogen is associated with a decrease in single-family home sale prices in the range of 0.407% to 0.807% (average 0.61%), with a 95% confidence level. During the study period the water quality in Three Bays degraded by 15.8%. The above range of estimated decrease translates into a noticeable fiscal impact on the community, both in terms of decrease in sale price and consequent impact on the assessed value.

Case Study: Three Bays cont.

For example, if the discharge of nitrogen into Three Bays waters was lessened resulting in a 3% decrease in total nitrogen level, average single-family home sale prices in the study area would have been $16,774 to $32,957 higher than in 2013. That translates into potential sale value loss (and consequent assessed value loss) in the range of $49 to $86 million in the study site alone (1,000m or ten-minute walking distance to the waterfront). No action in 2015 will bring additional loss of home value to Cape Cod due to degrading water quality from nitrogen.

Cape Cod's environment is linked directly to its economy. The nitrogen problem is a significant threat to both. Continued degradation of the coastal resources on Cape Cod will negatively impact the seasonal and year-round economies, affecting property values for year-round residents and second homeowners, and shifting property tax burdens away from higher value seasonally occupied coastal properties on to middle class year-round residents.

Cape Cod – Defined by Water

UNDERSTANDING THE PEOPLE AND THE PLACE BEFORE CONSIDERING SOLUTIONS

A glacial deposit created Cape Cod as a peninsula with Cape Cod Bay to the north, Nantucket Sound to the south, the Atlantic Ocean to the east, and a significant part of the western coastline bounded by Buzzards Bay. With the construction of the Cape Cod Canal circa 1914, the land mass became surrounded by water. Cape Cod has 560 miles of coastline, nearly 1,000 kettlehole ponds and a sole source aquifer.

LAND USE

Cape Cod's great natural beauty, bountiful recreational opportunities and proximity to major urban areas led to a rapid increase in population over the last half century. The Cape's traditional farming and fishing way of life underwent a slow transformation from the 1870s through the early part of the 20th century as seaside resorts began to attract summer visitors. The advent of rail travel and the adoption of the interstate highway system added to the accessibility and the popularity of Cape Cod. The population began to rise more quickly in the 1950s and even more steeply from the 1970s through the early 2000s, as Cape Cod became a desired location for retirees and second-home buyers. Most of this development was residential with associated commercial, industrial, and tourism-based land uses.

In the past several decades the number of people living year-round on Cape Cod increased, with a concomitant conversion of seasonal homes for year-round use. The 2010 US Census listed about 57,000 seasonal housing units, or approximately one third of the housing stock on Cape Cod. These seasonal homes are much more prevalent in coastal areas than inland on Cape Cod.

Balancing natural and human-built systems remains both a challenge and an opportunity. Open space in more sensitive areas improves the ability of the natural environment to further absorb human impacts as well as counteracting naturally occurring uncontrollable nitrogen loads from atmospheric deposition. Conversely, sprawling patterns of growth tend to increase infrastructure costs and make the delivery of services such as public transit less practical. The location of infrastructure and public facilities, and zoning support and drive land use patterns. The development of infrastructure, from wastewater to telecommunications, will be essential to regional economic growth that doesn't degrade the human or natural environment.

Plan Summary

WATER RESOURCES

MARINE WATER

Watersheds define the jurisdiction of the nitrogen problem.

Cape Cod is defined by and dependent on the marine environment that surrounds it. Nutrients and pollutants from land use development, including wastewater, are conveyed through groundwater to surrounding marine waters with concentrations and directional flows determined by watersheds.

Similar to water supply wells, watersheds to embayments are defined by groundwater flow paths of the aquifer. There are 101 watersheds to the surrounding marine waters. Of those, 53 are watersheds to coastal embayment systems, or partially enclosed coastal areas with varying degrees of tidal restriction. Coastal embayments are located at the margin of the aquifer and are the ultimate receiver of the aquifer's groundwater discharge.

Watersheds to coastal embayments extend from the coastline up to the top of the water table lens, located along the spine of the peninsula. They comprise nearly 79% of the land area of Cape Cod. The remaining land area is comprised of watersheds where groundwater discharges directly to open coastal water such as the Cape Cod Canal, Nantucket Sound, Cape Cod Bay and the Atlantic Ocean. These areas may be important to local nitrogen removal, remediation and restoration efforts given their decreased nitrogen sensitivity.

GROUNDWATER

The hydrogeology of Cape Cod is largely composed of coarse sands with considerable permeability. The travel time for wastewater pollutants from their initial entrance into groundwater to the point when they reach an embayment can be up to 100 years, but is less than 10 years across almost half of the region. This presents the likelihood that wastewater treatment options, once implemented, will result in water quality improvements within 5-10 years in some of its polluted embayments.

The Cape Cod Aquifer is one of the most productive groundwater systems in New England and provides 100% of the Cape's drinking water. It is a sole source aquifer providing drinking water to over 650,000 people during the peak tourist season and is derived from 158 gravel-packed municipal supply wells providing public water service to 85% of Cape Cod, and hundreds of private wells providing service to 15% of Cape Cod in the communities of Sandwich, West Barnstable, Eastham, Wellfleet and Truro. The aquifer is recharged from rain and ultimately conveys that water to the surrounding embayments, if not otherwise captured by wells and groundwater-fed ponds.

The Cape Cod Aquifer is extremely susceptible to contamination from various land uses and activities. The aquifer has been seriously impacted in the past from military activities, gas stations, landfills and other activities. The quality of Cape Cod's community public drinking water supply is generally very good, but over the past 15 years there has been a trend toward some degradation.

PONDS

The lakes and ponds on Cape Cod formed about 12,000 years ago during the last stage of the Wisconsinan glaciation. As glaciers retreated from Cape Cod, large chunks of ice were left behind. As these chunks of ice melted, the landscape above them collapsed, forming large depressions called kettle holes. Where these depressions dip below the groundwater table, they are filled with water and create the hundreds of ponds that exist on Cape Cod today.

Cape Cod has 996 ponds covering nearly 11,000 acres. These ponds range in size from less than an acre to 735 acres, with the 21 biggest ponds making up nearly half of the total Cape-wide pond acreage. Approximately 40% of the ponds are less than an acre. One hundred and sixty six are designated as great ponds of 10 acres or more.

Cape Cod's freshwater ponds are fragile systems especially vulnerable to pollution and human activity. The key nutrient of concern for freshwater ponds is phosphorus. Water quality in Cape Cod ponds is significantly impacted by surrounding development. A comparison of 1948 and 2001 dissolved oxygen concentrations suggest that many of these pond ecosystems are not only impacted, but also seriously impaired.

The fresh water ponds of Cape Cod provide a significant benefit in removing nitrogen as it moves through the watershed. Ponds provide natural attenuation of nitrogen in groundwater and are an important consideration in watershed planning, as they act as "nitrogen filters."

Existing Regulatory and Planning Framework

Water quality goals for the nation, the state, municipalities, districts and specifically for Cape Cod are reflected in a number of laws, regulations and plans, some regulating the problem and others focused more on the regulation of proposed solutions that can be identified in two categories – regulating the problem and regulating the solutions. The federal Clean Water Act and the state Title 5 regulations focus on the problem. The Massachusetts Environmental Policy Act, the Cape Cod Commission Regional Policy Plan and other local ordinances impact the siting of potential solutions on Cape Cod.

REGULATING THE PROBLEM

CLEAN WATER ACT

The US EPA regulates water quality under the Federal Water Pollution Control Act of 1972 and its subsequent amendments in 1977, 1981, and 1987. Collectively these are known as the Clean Water Act. The objective of the act is to maintain and restore the chemical, physical and biological integrity of US waters. The act requires states to establish ambient water quality standards for water bodies based on the need to protect the use(s) designated for that water body.

The Act regulates point sources under the National Pollutant Discharge Elimination System (NPDES) permit program. In most cases, the NPDES permit program is administered by authorized states on behalf of US EPA. Massachusetts is one of a handful of states that is not a delegated NPDES permit state; however, permits are jointly issued by the US EPA and the MassDEP and are equally and separately enforceable by both agencies.

Point Sources

The definition of a point source of pollution as stated in §502(14) of the Federal Clean Water Act is "any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged."

The Clean Water Act authorizes US EPA and states to regulate point sources that discharge pollutants into navigable waters of the United States through the NPDES permit program. These "point source" discharges are generated from a variety of residential, municipal and industrial operations, including treated wastewater, process water, cooling water, and stormwater runoff. The NPDES Stormwater Program regulates discharges from municipal separate storm sewer systems (MS4s), construction activities, industrial activities, and those designated by US EPA due to water quality impacts.

Nonpoint Sources

The term "nonpoint source" is defined as any source of water pollution that does not meet the above legal definition of a "point source." Nonpoint sources are typically described as those emanating from precipitation that has picked up natural and human-made pollutants as it moves over and through the ground. The US EPA lists fertilizers,

herbicides, pesticides, oil and grease, sediments and bacteria, and nutrients from "faulty septic systems" as examples of nonpoint source pollutants.

MASSACHUSETTS SURFACE WATER QUALITY STANDARDS

Following the federal law and as prescribed by the Federal Clean Water Act, the Commonwealth of Massachusetts adopted surface water quality standards for individual water bodies. The standards designate the most sensitive uses for which the water body must be "enhanced, maintained, and protected" (whether or not the designated use is currently attained), prescribe minimum water quality criteria necessary to sustain the designated uses and contain the regulations necessary to achieve and maintain the designated use and, where appropriate, prohibit discharges.

Massachusetts divides coastal and marine surface waters into three classes: SA, SB, and SC, in descending order of the most sensitive uses that water body must attain. Additionally the state has special designations of Outstanding Resource Waters, Special Resource Waters, Shellfish (waters), and Warm Water.

IMPAIRED WATERS AND TOTAL MAXIMUM DAILY LOADS

The Clean Water Act, under s.305(b) , requires states to assess the quality of surface waters based on the designated uses biennially (every 2 years) and to develop a list, referred to as the 303(d) list, of impaired waters—those waters that do not meet the designated uses. The most recent impaired waters list for MA, including Cape Cod waters, is the Massachusetts Year 2012 Integrated List of Waters; however, a draft 2014 list is also available. Under §303(d) of the Clean Water Act, states are required to:

- Identify those water bodies that are not expected to meet the Surface Water Quality Standards; and,
- Establish, subject to US EPA approval, for those waters total maximum daily loads (TMDLs) - a calculation of the maximum amount of a pollutant that a water body can receive and still meet water quality standards.

On Cape Cod, state-developed TMDLs are based on technical reports prepared by MEP. TMDLs are formulated by MassDEP and submitted to the US EPA for approval after public comment.

TITLE 5

MassDEP regulates wastewater flows less than 10,000 gallons per day under 310 CMR 15.000: The State Environmental Code, Title 5: Standard Requirements for the Siting, Construction, Inspection, Upgrade and Expansion of On-Site Sewage Treatment and Disposal Systems and for the Transport and Disposal of Septage (typically referred to as Title 5). Most of Cape Cod's development is regulated by Title 5. Only 5of the 15 municipalities on Cape Cod utilize centralized collection and advanced treatment. Title 5 covers such uses as conventional on-site septic systems, alternative systems, such as denitrifying systems (often called "Innovative/Alternative," or I/A, systems), as well as composting toilets and other kinds of systems in use on individual properties or cluster developments. Title 5 presumes residential wastewater flows at 110 gallons per day per bedroom (e.g., Title 5 presumes that a four-bedroom house will generate 440 gallons per day). Non-residential wastewater generation is typically based on use and square footage, or the number of restaurant seats.

MassDEP may identify certain areas as particularly sensitive to pollution from on-site wastewater systems and therefore require the imposition of loading restrictions. These Nitrogen Sensitive Areas (NSAs) include:

- Interim Wellhead Protection Areas and department-approved Zone IIs of public water supplies
- Areas with private wells

- Nitrogen-sensitive embayments or other areas, which are designated as nitrogen sensitive under Title 5 based on appropriate scientific evidence

The nitrogen-loading restrictions in NSAs apply to new construction only and do not affect existing Title 5 systems unless they are deemed to have failed or are required to be upgraded at the time of property transfer. To date, MassDEP has been reluctant to designate NSAs on Cape Cod because they don't solve the problem..

GROUNDWATER DISCHARGE PERMIT PROGRAM

Flows in excess of 10,000 gallons per day are regulated under the state Groundwater Discharge Permit Program. Systems requiring a groundwater discharge permit require significant removal of nitrogen because the Cape Cod Aquifer is designated as a non-degradation resource. Groundwater discharge permits for Cape Cod require an effluent treatment level of at least 10 milligrams per liter of nitrate, which is almost a two-thirds reduction in the amount of nitrogen leaving a septic system. In the last 10 years, groundwater discharge permits for projects located in watersheds to impaired embayments have been held to a "no-net nitrogen" standard by MassDEP. This means that any nitrogen released into the watershed must be "offset" by the removal of nitrogen from an existing source. To date, this typically occurs by connecting a nearby existing development to remove nitrogen via wastewater treatment.

REGULATING THE SOLUTION

COMPREHENSIVE WASTEWATER MANAGEMENT PLANS

Currently, individual municipalities develop Comprehensive Wastewater Management Plans (CWMPs) within town boundaries. These plans include watersheds that are both wholly within town boundaries, and shared with a neighboring town(s). MassDEP considers requests for municipal permits and financing after the state level environmental scoping review is conducted under the Massachusetts Environmental Policy Act (MEPA).

The MassDEP Division of Municipal Services Guide to Comprehensive Wastewater Management Planning outlines the process for development of a CWMP. According to the guidance, "The planning exercise requires a community to perform a needs analysis: identifying problem areas."

CWMPs have traditionally recommended conventional wastewater sewer collection and treatment facilities, which require groundwater discharge permits and sewer construction permits.

MASSACHUSETTS ENVIRONMENTAL POLICY ACT AND OTHER STATE REGULATIONS

Comprehensive Wastewater Management Plans typically require MEPA review prior to state and regional permitting. MEPA review involves scoping proposed projects for their potential environmental impacts, identifying alternatives, and avoiding, minimizing or mitigating environmental impacts. CWMPs are typically filed first as an Environmental Notification Form (ENF) or Expanded ENF with a Draft Environmental Impact Report (DEIR) and released for public comment. At the end of public comment, the Secretary of Energy and Environmental Affairs will issue a Certificate of Adequacy that outlines additional information or analysis that should be conducted prior to the next MEPA filing. The final MEPA filing is a Final Environmental Impact Report (FEIR). Upon the Secretary's issuance of a Certificate of Adequacy for an FEIR, appropriate state agencies and the Cape Cod Commission then commence their regulatory reviews. In addition to MassDEP regulatory review, other state agency permits may include: Massachusetts Natural Heritage and Endangered Species Program; Massachusetts Historical Commission; Massachusetts Division of Marine Fisheries, and others.

REGIONAL POLICY PLAN

The Cape Cod Commission Act (Act) established a Commission regulatory function to review and approve, condition, or deny development projects that exceed Development of Regional Impact (DRI) thresholds. The Act includes a provision that the Commission develop and implement a Regional Policy Plan (RPP) that contains the minimum performance standards (MPS) for its regulatory

review of proposals. The Commission published the first version of the Regional Policy Plan in 1991; it has been updated and revised every five years. All revisions to the RPP are approved as ordinances by the Barnstable County Assembly of Delegates, the regional government's elected legislative body.

A Development of Regional Impact is a proposed development that is likely to present development issues significant to more than one municipality in Barnstable County. Projects are referred to the Cape Cod Commission for review as DRIs by a variety of means.

Municipalities are typically required to file an Environmental Impact Report (EIR) with the MEPA Unit for the development of CWMPs. The Cape Cod Commission Act (§12(i)) requires that the Commission shall review as a DRI any proposed development project for which the Massachusetts Secretary of Energy and Environmental Affairs requires the preparation of an EIR. As a result, the Commission conducts a regulatory review, generally concluding with a written approval decision containing findings and conditions for all CWMPs proposed by Cape Cod towns. CWMPs typically trigger EIR review because they involve construction of a new wastewater treatment and disposal facility with a capacity of 2,500,000 gallons per day, or because they result in construction of one or more new sewer mains 10 or more miles long. CWMPs may also trigger mandatory EIR thresholds for land and wetland alterations, impacts to endangered or threatened species or archeological sites, and other factors.

The Commission's regulatory review of a CWMP is presently guided by the planning guidance and minimum performance standards of the Regional Policy Plan. The pertinent technical sections of the RPP include water resources, open space, natural resources, planning and historic preservation. Some of the requirements are similar to MassDEP requirements, but some are quite different.

The 2009 Regional Policy Plan changed the "no net" policy to reflect the newly adopted TMDLs by MassDEP and US EPA as the critical nitrogen loading limit. The performance standard interprets the adopted TMDL as a "fair share." The fair share is the TMDL equivalent load to be allocated to contributing towns on a per-acre rate using the watershed and sub-watershed area.

LOCAL REGULATION

Local zoning, board of health regulations and conservation commission regulations also often impact the selection and siting of wastewater treatment technologies and approaches.

What Is Being Done?

MASSACHUSETTS ESTUARIES PROJECT

In 2001, MassDEP and the University of Massachusetts School for Marine Science and Technology, in collaboration with the Cape Cod Commission, established the Massachusetts Estuaries Project.

MEP scientists developed models that link nitrogen loading in a watershed to coastal water quality. Inputs into the models include data on coastal water quality, tidal flushing, bathymetry, pond water quality, current and historic eelgrass coverage, water use, wastewater treatment plant performance (if any), landfill monitoring, watershed delineations, sediment nutrient regeneration, and nitrogen attenuation from wetlands, rivers and freshwater ponds. The modeling results confirmed earlier studies identifying on-site septic systems as the major source of nitrogen to coastal embayments.

In response to concerns raised by some Cape Cod communities regarding the validity of the MEP scientific approach, the Barnstable County Commissioners directed the Cape Cod Water Protection Collaborative (Collaborative) to undertake a scientific peer review of the MEP process. In 2011, the Collaborative organized an independent scientific peer review of the MEP methodology for developing appropriate TMDLs for the estuaries and embayments of

Cape Cod, and for the use of that methodology as a basis for wastewater and nutrient management planning and implementation on Cape Cod. The scientific peer review process was independent and objective, and operated externally from the Collaborative and from any other Cape Cod stakeholders.

The peer review panel found the MEP modeling approach to be appropriate and useful for evaluating alternative scenarios and informing nutrient management plans, and also found the MEP to be consistent with existing nationwide TMDL practices. The panel also found that the MEP modeling approach is scientifically credible, and the modeling approach is consistent with current understanding of existing conditions for Cape Cod estuaries, based on available data. The components in the approach are well known and documented. Computation of watershed nitrogen loads is strongly data-driven and quantitatively linked to estuarine nitrogen concentrations.

The MEP partnered with Cape Cod communities to evaluate coastal water quality and develop technical reports recommending water quality targets for nitrogen that MassDEP utilizes to develop TMDLs. Model results are presented in published technical reports, and identify one potential scenario indicating how much nitrogen must be removed from wastewater to meet the water quality target in a particular coastal embayment.

The MEP was estimated to cost $12 million over six years. Funding is broad-based with half coming from the state and the other half coming from local and other agency sources. Barnstable County, through the Cape Cod Commission, provided over $700,000 to the MEP over the last eight years as direct assistance to participating Cape Cod towns. The MEP's regionally consistent methodology provides technical work and documents at significant cost savings over towns undertaking similar work individually.

The MEP developed a rigorous Linked-Model approach that includes components of the various disciplines necessary to understand and project how nonpoint source nitrogen loading in a watershed translates into coastal water quality deterioration. Data input into these models includes: three years of volunteer-collected coastal water quality data, tidal flushing data, bathymetric information for estuaries and freshwater ponds, pond water quality data, current and historic eelgrass coverage, water use information, wastewater treatment plant performance, landfill monitoring data, watershed delineations, sediment nutrient regeneration, and wetland nitrogen attenuation.

Embayments on the southern coast of Cape Cod are typically more susceptible to impacts because the tidal range is generally 1/2 to 1/3 of the range observed in Cape Cod Bay to the north.

As of February 2015, 35 watersheds have completed MEP technical reports, two are in draft form, and four are pending.

The MEP provides specific documentation, based on water quality testing, that many of Cape Cod's watersheds have impaired water quality and ecological damage due to nitrogen loading. Nitrogen from septic systems accounts for approximately 80% of the watershed load, with stormwater and fertilizers accounting for the remainder of the locally-controllable nitrogen load. Atmospheric deposition of nitrogen in rainfall is another source accounted for in the stormwater runoff contribution for the watershed and as direct rainfall on the embayment itself.

The MEP technical reports and TMDLs contain estimates for how much watershed nitrogen needs to be removed to meet the TMDL. Since septic system contributions represent the greatest controllable nitrogen load in Cape Cod watersheds, TMDLs also specify how much wastewater nitrogen from septic systems would need to be removed to meet the TMDL. The average removal rate for septic nitrogen load to meet water quality standards exceeds 50% Capewide.

Plan Summary

CAPE COD COMMISSION

Concurrent with the beginning of our awareness about coastal waters, the Commission adopted a regulatory requirement that development projects within watersheds to water quality impaired embayments should have no-net nitrogen loading. In other words, the amount of nitrogen added by the project must be offset by an equivalent reduction. Several County-appointed committees that reviewed the Commission's regulatory program accepted this requirement as a necessary interim step to halt continued degradation of the Cape's coastal water quality. Over the years, it became increasingly clear to organizations involved in assessing and protecting embayments that a comprehensive effort to link regulatory and scientific activities was necessary to realize solutions for observed coastal water quality problems.

POND AND LAKE STEWARDSHIP

In 2001 a coalition of groups interested in protecting ponds received a $30,000 grant to develop a Cape Cod pond stewardship strategy from the Massachusetts Watershed Initiative, known as the Ponds and Lakes Stewardship (PALS) project. The Cape Cod Pond and Lake Atlas, published by the Cape Cod Commission in 2003, provides a status report on the PALS program. It documents the outreach and education activities leading to the creation of the PALS program, reviews water quality data collected by volunteers during the 2001 PALS Snapshot from over 190 ponds, uses this data to develop Cape Cod-specific indicators of pond impacts, reviews data collected in previous studies, and details further efforts necessary to move pond protection and remediation forward on the Cape.

BARNSTABLE COUNTY HEALTH DEPARTMENT

MASSACHUSETTS ALTERNATIVE SEPTIC SYSTEM TEST CENTER

The Massachusetts Alternative Septic System Test Center opened in 2000 to research and test advanced on-site wastewater treatment systems. The Center is operated by the Barnstable County Department of Health and the Environment (BCDHE) and is located at Joint Base Cape Cod. Although the Center's initial emphasis was on nutrient-reducing technologies, more recently it conducted research on the efficacy of commercial and soils-based septic systems for removal of pharmaceuticals and personal care products. The Center has been instrumental in forming and conducting many internationally recognized standards for both secondary and tertiary wastewater treatment. Ancillary projects include the support of research efforts on wastewater diversion techniques, such as composting toilets and urine diversion, and their efficacy for addressing the nutrient management issues in sensitive watersheds. The majority of the systems tested at the Center are proprietary systems and the efficacies of non-proprietary denitrification strategies are less understood, primarily due to the lack of financial incentives to develop and promote them. It is clear, however, that Cape Cod communities are interested in exploring all options available to reduce nitrogen that enters the groundwater. Through this update of the Section 208 Plan for Cape Cod, funding was provided to the Barnstable County Department of Health and the Environment to investigate non-proprietary means to remove nitrogen by enhancing and/or manipulating soils-based systems.

INNOVATIVE/ALTERNATIVE SEPTIC SYSTEMS PERFORMANCE TRACKING

More than 1,500 innovative/alternative (I/A) septic systems have been installed on Cape Cod in an attempt to reduce the amount of nitrogen discharged into the groundwater. These systems range in their complexity, but all require regular maintenance and monitoring. Since 1999, BCDHE has maintained a database to assist regulators in the task of tracking performance and adherence to maintenance schedules. Regular performance and compliance updates are provided to local regulatory boards. More recently, to aid the public and engineering professionals, the department has created an interactive tool to chart performance of all technologies used within Barnstable County. This tool assists wastewater planners to

develop realistic performance expectations, thus facilitating accurate CWMPs. Occasionally printed compendia of the information are distributed to local boards and commissions. The department also maintains training tools to instruct boards of health regarding the proper application of these technologies.

COMMUNITY SEPTIC MANAGEMENT LOAN PROGRAM

The Barnstable County Department of Health and the Environment initiated the Community Septic Management Loan Program to assist homeowners by defraying the costs of septic system upgrades through provision of 20-year betterments. More recently the program has assisted in providing support for the actual connection costs to centralized systems or combined packaged or cluster treatment systems. Barnstable County administers this program regionally for all Cape Cod towns.

CAPE COD WATER PROTECTION COLLABORATIVE

The Cape Cod Water Protection Collaborative was created by county ordinance in 2005 and exists to offer a coordinated approach to enhance the water and wastewater management efforts of towns, the regional government and the broader community. The Collaborative seeks to protect Cape Cod's shared water resources and to provide access to cost effective and environmentally sound wastewater infrastructure. The Collaborative seeks funding support for Cape communities, establishes priorities, directs strategy, builds support for action, and fosters regionalism.

TOWNS

All 15 Cape Cod towns have engaged to some degree in the process of developing CWMPs over the last 10 years. Several towns are in the MEPA review process. A Cape Cod Commission regulatory review file of comment letters, public hearings and decision documents are available for each town that is undergoing the MEPA/DRI review process for their CWMP. Towns with existing wastewater infrastructure including Barnstable, Chatham, Falmouth and Provincetown, completed wastewater facilities plans prior to or in conjunction with nutrient planning.

Why Hasn't There Been More Progress?

Despite the efforts described above, few communities have implemented nitrogen remediation programs that will meet water quality standards.

COST

Cost has been the major impediment to wastewater plans on Cape Cod. The existing wastewater costs to homeowners are hidden. Most people don't recognize the annualized expense of owning and maintaining a Title 5 system.

More than 30% of the housing stock in the region is seasonal. In some towns that figure is as much as 60%. This creates a peak-flow pricing issue for most towns because facilities are sized for a peak flow which occurs only four weeks a year - the last two weeks of July and the first two weeks of August. Less than 4% of the state's population lives on Cape Cod yet the region is home to 20% of the Title 5 systems.

Towns need to stimulate their tax base in order to afford the wastewater costs necessary to meet water quality standards and, at the same time, the economic development necessary to achieve that result is limited by the problem that needs to be solved. Without additional ability to treat wastewater, towns don't have the capacity for appropriate nitrogen-reducing patterns of growth.

LACK OF LOCAL CONSENSUS

Progress on water quality issues related to wastewater is always challenging. The solutions are generally expensive and it is easy for people not to think about what happens after they flush. Education efforts on Cape Cod have been

successful in identifying wastewater as a problem but more work is necessary for a majority of people to recognize that septic systems contribute most to the problem.

Local planning and zoning were ineffective in preventing sprawled residential development patterns that increase the cost of conventional wastewater solutions.

The politics of wastewater is difficult. On the Cape, towns are the primary fiscal agents involved in building wastewater systems. Appropriations on a municipal level that authorize borrowing require a two-thirds vote of the local legislative body. In the Town of Barnstable that is the Town Council. In the other 14 towns the legislative body is town meeting.

LACK OF ENFORCEMENT

Federal and state enforcement tools are imperfect and rely on permitting dischargers. Current enforcement actions would lead to expensive compliance requirements without necessarily resulting in achieving water quality goals.

The web of federal and state regulations governing wastewater management were created to address the water quality challenges of 40 years ago. While the important goals of those efforts remain applicable, the regulatory scheme driving planning and design efforts to meet those goals is inflexible and poorly suited to solving the problems facing the Cape. The current regulations favor centralized treatment approaches and have no effective means for incorporating alternative approaches into a conventional permit.

REGULATIONS LIMIT OPTIONS AND INNOVATION

The regulatory framework in place was built to solve other problems. Existing regulatory drivers overbuild expensive solutions dependent on point-source technologies to solve a nonpoint source problem. This doesn't account for the unique challenges of Cape Cod as a coastal community with a marine water quality issue caused by nutrients and a relatively low-density development pattern.

This plan highlights the need for modifications to the regulatory approach to reflect the predominance of septic system effluent as the primary problem to be solved and to expand the use of alternative and non-traditional technologies and management strategies necessary to meet the unique circumstances of Cape Cod. State development of a watershed permitting process is the essential step in reforming the regulatory environment to unlock the financial savings and management potential of watershed based solutions that rely on a mix of technologies and approaches. Other regulatory reforms are recommended to create the right incentives for the implementation of 21st century solutions to a problem that has been long developing.

The Cape Cod Model

This update provides a regional analysis of watersheds and the nitrogen problem. The review of local nutrient management planning, consideration of the best available scientific assessments and the collection of all relevant geographic data resulted in a recommended new approach to solving the nitrogen problem with specific strategies for better designed and effective watershed-based solution at lower cost with more community support.

COMMUNITY ENGAGEMENT

The Cape Cod Commission committed to an extensive public engagement process to bring more voices to the table in order to develop consensus around a range of solutions to solve water quality problems. The public participation and engagement process was Cape-wide and included both subregional and watershed specific working groups.

There were a number of challenges associated with the complexity of the task and the short time frame for completion. The challenges included:

- Ensuring a high level of process objectivity,
- Staying on task and on time,
- Coming to agreement on potential solutions,
- Addressing the issue of affordability,

- Creating opportunities for regulatory flexibility, and
- Educating and engaging the broader Cape Cod community.

The process took advantage of existing teams and created new teams to tackle each challenge efficiently and effectively.

EXISTING TEAMS

Existing Cape-wide organizations already working on wastewater and nutrient management issues were enlisted to avoid redundant effort and transfer existing knowledge, expertise and data sets.

Cape Cod Water Protection Collaborative Governing Board and Technical Advisory Committee

The Governing Board of the Collaborative reinstated monthly meetings in May 2013 to follow the Section 208 Plan Update process. The Governing Board has 17-members and approves all expenditures, policies and strategies of the Collaborative. Membership consists of an appointed member from each town in addition to two County Commissioners' appointees.

In addition, the Technical Advisory Committee (TAC) of the Cape Cod Water Protection Collaborative was reformed and re-chartered to look at some of the technical aspects of the Section 208 Plan Update. Specifically, the TAC reviewed and commented on the Water Quality Technologies Matrix and helped to develop and refine a series of one-page fact sheets for watershed stakeholders and community use. The TAC consists of one appointed representative from each town and a MassDEP representative to provide the regulatory, permitting and technical perspectives.

NEW TEAMS

New teams were created, as necessary, to provide overall guidance on the plan's progress and separate subject matter advice. Each team established a timeframe for performance and an agreed upon statement of purpose.

Regulatory, Legal and Institutional Work Group

A Regulatory, Legal, and Institutional (RLI) Work Group, with representation from MassDEP, US EPA, the Cape Cod Commission, and other State and Federal partners, as necessary, addressed the potential need for regulatory reform and other challenges associated with planning and implementation. Increased coordination between local, state and federal regulatory requirements was identified by the Commission as a need moving forward and the group met monthly to discuss this and other opportunities and challenges related to the Section 208 Plan Update.

Advisory Board

A six-person advisory board, which meets monthly, was convened with representation from the four subregional planning areas, along with two ad hoc members. Members have current or prior experience in municipal government and/or experience with other regional-scale issues, such as the groundwater cleanup at Joint Base Cape Cod and regionalizing school districts. The mission of the board is to support the Section 208 Plan Update planning process by providing advice on the overall approach, reviewing draft work product and offering insight on strategic and tactical decision-making.

Finance Committee

A Finance Committee, which meets monthly, was convened with representation from local communities and support from consultants to the Cape Cod Commission for the Section 208 Plan Update. Members include a town administrator, a finance director and a municipal finance committee member. The mission of the committee is to work with the consultants to the Commission to establish a factual basis for discussing issues of affordability, financing and resources related to the Section 208 Plan Update.

Technologies Panel

A Technologies Panel, which met four times over the course of two months, was convened to review, confirm, and

expand upon the matrix of technology options developed through and used in the Section 208 Plan Update process, review the overall planning approach in each watershed, and provide input on a site screening methodology for green infrastructure technologies. The panel consisted of local, national, and international experts on the impact of nutrients in coastal waters, remediation approaches, and emerging technologies.

Monitoring Committee

A Monitoring Committee, which meets monthly, was convened in April 2014. The mission of the committee is to provide advice and guidance on appropriate monitoring protocols for technology efficiency and total maximum daily loads, while identifying a process for consolidating all available monitoring data in a central location and format. Members include representatives from MassDEP, US EPA, academic institutions, non-profit organizations, and other government agencies. Among the roles and responsibilities of this committee are to:

- Establish performance monitoring protocols for technologies that may be a part of watershed permits in the future;
- Establish compliance monitoring protocols for meeting TMDLs in the water body;
- Establish process and structure for consolidating and cooperation of existing monitoring programs and data in to a centralized location; and
- Identify region-wide monitoring needs and develop proposals.

WEB-BASED CAPE-WIDE ENGAGEMENT

In an effort to reach groups not normally associated with wastewater or planning projects in general we employed a web-based Cape-wide engagement project. In conjunction with Emerson College's Engagement Game Lab, the Commission tailored the Community PlanIt platform to create and run CAPE2O, an on-line game-based engagement tool. Two different three-week games saw more than 900 people register and generated more than 6,000 comments and questions on water quality issues. CAPE2O introduced players to the nutrient problems on Cape Cod through different problem-solving perspectives including science, civics, economics and consensus building.

STAKEHOLDER ENGAGEMENT

Subregional Public Meetings

To start the stakeholder process, two meetings were held in each of the four subregions – one in July 2013 to introduce the process and develop the watershed working groups and one in August 2013 to introduce information around affordability of infrastructure and discuss what people on Cape Cod are currently paying for water and wastewater infrastructure. These meetings helped to engage the communities and establish the watershed working groups discussed above. The purpose of the subregional meetings was also to recruit stakeholders.

Watershed Working Groups

Working groups, made up of 15-20 self-selected stakeholders (about 170 people Cape-wide), were associated with each watershed group and subregional group. Each working group consisted of the following general representation: Local Elected Officials, Wastewater Committee Members, Town Professional Staff, Local Business Owners/Operators, Local Environmental Organizations, Civic Group Members, Alternative Technology Interests, Development/Real Estate Community and Interested/Concerned Citizens.

In Fall 2013, each working group met three times in four-hour-long professionally facilitated meetings – once in September to discuss the baseline information in each of their watersheds, including land use, nitrogen related water quality impairments, pond water quality, and existing and proposed infrastructure, once in October to discuss the

range of technologies and approaches that might be used on Cape Cod, and once in December to discuss the process for applying technologies and approaches in each watershed.

Subregional Working Groups

Following the three sets of watershed working group meetings the conversation shifted from discussing the jurisdiction of the problem, at the watershed level, to the jurisdiction of the solution, at the subregional level. In early 2014, watershed working groups were asked to self-select into subregional groups, with representation from each of the watershed working groups and in each of the categories established as part of the watershed working group process.

The structure of the subregional meetings was different from the watershed working group meetings, which had discrete topics associated with each meeting. The subregional meetings were iterative, with a standing agenda that included scenario planning; regulatory, legal, and institutional issues; and implementation. Each subregion met three times in four-hour-long meetings. Meetings included representation from MassDEP and US EPA and were also professionally facilitated.

CAPE-WIDE MEETINGS

On November 13, 2013, the Commission held a Watershed Event to conclude the Cape20 game, award prizes to participants and provide funding to top projects associated with the game. About 120 people attended, including stakeholders and Cape20 players, regulatory agency staff, and members of the public. Speakers included Cape and Islands Senator Dan Wolf, as well as representatives from the US EPA and MassDEP. In addition to discussing the outcomes of the Cape20 game the time was used to begin the discussion around structuring the second half of the stakeholder engagement process – the subregional working group meetings.

On February 6, 2014, the Commission held a day-long Stakeholder Summit to review the work to date and discuss the path toward development of the Section 208 Plan Update. About 270 stakeholders, regulatory agency staff, and members of the public attended the event. Speakers included the State Treasurer, MassDEP Commissioner, CEO of the Cape Cod Chamber of Commerce, representatives from the US EPA and the Cape Cod Commission. The discussion focused on the importance of community involvement in the Section 208 Plan Update planning process and the need to meet water quality goals in Cape Cod's estuaries. Breakout sessions included preliminary conversations on scenario planning, regulatory, legal, and institutional issues, and implementation issues, in order to set the stage for the upcoming Subregional Working Group sessions.

TECHNICAL REVIEW

A WATERSHED APPROACH

A watershed approach looks at the jurisdiction of the problem – all of the contributing sources within a watershed (or the receiving water itself), without regard to political boundaries. A watershed is a geographic area separated from other regions by drainage divides, within which all water flows to a common outlet, such as an embayment. Watersheds do not follow the municipal boundaries separating one town from another. Of the 53 watersheds to coastal embayments addressed in this document, 32 are shared by more than one town. Although wastewater planning has been underway on Cape Cod for more than a decade, the current process has been uncoordinated and in many areas represents only a partial solution to the problem resulting in approval of municipal CWMP's that will not meet water quality standards in shared water bodies.

SOLUTIONS CLASSIFIED AND EVALUATED

This report examines 10 categories and a total of 67 nutrient reduction, remediation, and restoration technologies and approaches. Both conventional and alternative means are represented in those groupings. This

work is embodied in the Water Quality Technologies Matrix and then simplified based on the point of intervention and the scale of the technology or approach.

At what point in the nitrogen cycle the intervention takes place determines if the effort is reducing the nitrogen load at the source or reducing the impact of nitrogen already loaded into the ground water or the affected water body. This report classifies technologies and approaches as Reduction, Remediation, and Restoration interventions.

Technologies and approaches considered can be more or less effective and efficient depending on the scale of use. This report groups them based on Site, Neighborhood, Watershed or Cape-wide applicability. It is important to note that not every technology and approach is appropriate for every watershed. Evaluation of these options with the tools developed as part of the Section 208 Plan Update and detailed below is necessary as a preliminary step placing selected options in a watershed-specific scenario.

INFORMATION AND DECISION SUPPORT TOOLS

The process of collecting and analyzing such a large and comprehensive amount of information and a need to organize and analyze many geospatial data layers simultaneously produced a number of important new information products. These new decision support tools and the supporting databases and methodologies will be available through the Cape Cod Commission's Watershed Team technical assistance program. These tools make complex data sets more easily understood and provide an avenue for increased and informed deliberation at the local and hyper-local planning levels. This will expedite the selection and implementation of watershed solutions.

TWO PERSPECTIVES ON ONE PROBLEM

Implementation of wastewater solutions have failed to garner the 2/3rds Town Meeting votes necessary to appropriate money to build in most communities. Many of the plans have suffered a "death by a thousand cuts." The arguments against tend to fall into three categories: Science, Solutions (proposed strategies and technologies) and Cost.

As noted above, a group of experts was empaneled to review the scientific underpinning of the Massachusetts Estuary Project and approved its use by communities in making directionally correct decisions regarding solutions.

This document outlines a technical review process designed to provide insight into the remaining two categories, Solutions and Cost. The concerns often resulted in polarizing local debates, sometimes discussed in terms of centralized versus de-centralized approaches or traditional solutions versus alternative solutions. One of the key distinctions depends on a considered option's reliance on a permanent physical connection among multiple sources, a collection system. The process outlined in this report grouped points of view associated with these categorizations into two approaches to solving Cape Cod's nitrogen problem: a traditional approach and a non-traditional approach.

Two teams worked independently in the application of agreed upon conditions outlined as follows:

- Both approaches consider the entire controllable load.
- Both start with identified nitrogen reduction targets.
- Both agree that nutrient reduction goals can be adjusted based on a watershed's adoption of certain policies that will reduce or eliminate nutrient loading from certain sources, fertilizer reduction and stormwater management.
- Both approaches illustrate an attempt to solve the problem within the boundaries of the watershed as an environmentally preferable result, when possible.
- As a mutual point of reference, the traditional team evaluated a hypothetical analysis of an "all sewer" scenario and compared it to an "all innovative/alternative septic system" scenario. Neither was a best choice for taxpayers or the environment. This evaluation suggested scenario approaches be targeted and mixed, where appropriate.

Traditional Approach Process

The traditional (collection system) approach considered the greatest controllable source of pollution as a percentage of the whole, aggregated nitrogen in the most efficient grouping of sources, and suggested collection and treatment options.

Starting with the agreed upon nitrogen removal target, the review team applied low barrier technologies and approaches, applying nitrogen reduction credits to the watershed for fertilizer reductions and stormwater management. They targeted and identified nitrogen loads and an appropriate collection system to treat and dispose effluent within the watershed. Next the team adjusted the size of the necessary collection by considering treatment and disposal outside of the watershed. The process illustrates the cost and effectiveness of traditional strategies, potential economies of scale with shared treatment and disposal, and potential limitations to the environmentally preferred option of a watershed-based solution. The traditional approach provides an instructive backdrop for an adaptive management approach to managing nitrogen in watersheds.

Non-Traditional Approach Process

The non-traditional approach started with the premise that collection systems should be avoided or minimized to the greatest extent possible. Although conventional wisdom and practice suggests that economies of scale in the construction of wastewater treatment facilities result in the least expensive and most effective treatment, there is valid concern that the case studies supporting this view are from more urban communities with existing but degraded infrastructure. Cape Cod is missing both of these qualifications, having neither the density characteristics nor the existing infrastructure. The Cape also has an attribute not shared by other communities - its seasonal second home owner economy, which creates a peak-flow problem when building wastewater treatment facilities and creates a situation where facilities are overbuilt for 48 of 52 weeks a year.

Additionally, there are people in every community advocating for wastewater solutions that rely less on structural interventions and favor those that enhance natural systems. The technologies and strategies prioritized in the non-traditional approach also tend to result in less movement of water between watersheds and put a greater emphasis on comprehensive system restoration or improvement.

The non-traditional approach team began with the same nitrogen removal target as the traditional team and applied low barrier technologies and approaches, assigning nitrogen reduction credits to the watershed for fertilizer reductions and stormwater management. It then considered an array of watershed/embayment options, as detailed in the Water Quality Technologies Matrix, consisting of a broad range of innovative and non-traditional nitrogen management strategies to either intercept and treat nitrogen in the groundwater or to assimilate and treat them in the receiving waters.

Watershed practices include permeable reactive barriers (PRBs), constructed wetlands, phytoremediation, and fertigation wells, among others. Embayment treatment practices include, but are not limited to, shellfish bed restoration, aquaculture, floating wetlands, dredging and inlet modifications.

The next step considered alternative on-site options that have been screened for geographic suitability. A number of alternative wastewater source controls were evaluated in this step. These include ecotoilets and I/A septic systems. Ecotoilets are alternative toilets that target the source within the building. These include urine diversion (UD), composting, incinerating, and packaging toilets where the waste materials are collected and temporarily stored before processing. These technologies allow little or no human waste to enter the septic system (only gray water from the shower, laundry and sinks).

Social acceptability issues had the team using these strategies in a targeted way, schools for example.

Plan Summary

Among the actions needed to validate the efficacy of non-traditional approachesare piloting, monitoring and analyzing technology performance.

The non-traditional approach produced a targeted starting point for consideration as part of an adaptive management program in most watersheds.

MONITORING

In order for a broader range of technologies and options to be considered a long-term monitoring program must be established to provide technology specific monitoring protocols as well as an enhanced water quality monitoring program in the degraded water bodies.

ADAPTIVE MANAGEMENT

This recommended approach creates a predictable framework for adaptive management. It will allow communities to move forward in a targeted manner to begin to address marine water quality issues now. The traditional and non-traditional approaches can serve as the outer bounds of an adaptive management plan.

ADAPTIVE PLANNING

Although two independent watershed evaluation strategies were used the results have produced a recommended hybrid watershed planning approach. Included in this approach is the consideration of additional non-nitrogen collection needs in the watershed and expanded options for nitrogen reduction, remediation and restoration efforts producing watershed scenarios vetted by a community engagement process producing an adaptive management plan to be incorporated in a watershed permit.

Conclusion

The qualitative water quality goals of the Clean Water Act are not being met on Cape Cod. We are moving in the wrong direction. There has been no debate about the goal of clean water, but the regulatory drivers are producing point source solutions for non-point source problems. Regulatory enforcement actions based on quantitative measures are clear for point source discharges but not for non-point sources. The resulting dissonance has led to litigation attempting to define nutrient pollution related to wastewater as a point source to access more established enforcement action. The discussion has to move beyond this legal impasse. This update focuses on promoting more efficient and effective non-point source strategies designed to meet the qualitative goals of the Clean Water Act.

An update to the Clean Water Act that promotes and supports a non-point source nutrient control program and provides a clear path to compliance for communities will allow the goals of the Act to be more effectively and efficiently realized. The Commonwealth of Massachusetts has an opportunity to allow an innovative and common sense approach to solving the problem.The biggest controllable source of nitrogen on Cape Cod is subject to existing state authority. This update provides a path toward clean water based on the best information available that will make it easier for the 15 towns on Cape Cod to implement effective solutions without excessive costs.

This Section 208 Plan Update recommends actions to streamline the regulatory process, make complex information more transparent and available to citizens, abate nitrogen-induced costs already impacting the region, provide more support to local community water quality efforts, and eliminate unnecessary costs.

Introduction

As the population of Cape Cod increased over the last several decades, so has the volume of nutrients entering its coastal waters and freshwater ponds. The population of Cape Cod has increased by about 60% since the completion of the 1978 Water Quality Management (WQM) Plan, developed under Section 208 of the Federal Clean Water Act by the Cape Cod Planning and Economic Development Commission (CCPEDC), the predecessor to the Cape Cod Commission (Commission). Development associated with this growth is largely in the form of residences. Wastewater from both older and newer housing stock is predominantly treated by on-site septic systems that do not adequately remove nitrogen. Nitrogen from these systems is released to groundwater which ultimately discharges to the surrounding coastal waters. Excessive nutrients, such as nitrogen and phosphorus, are the documented cause of eutrophication in a majority of Cape Cod estuaries and freshwater ponds. In estuarine systems, nitrogen leads directly to thick mats of algae that replace eelgrass, diminish shellfisheries, and decrease dissolved-oxygen concentrations—occasionally leading to fish and shellfish kills, odor and frequent violations of water quality standards.

Cape Cod has less than 4% of the population of the Commonwealth but 20% of the septic systems. Only 3% of the parcels and 15% of the wastewater that flows on Cape Cod are centrally treated. Wastewater accounts for about 80% of the controllable nitrogen load entering Cape Cod's coastal waters.

This report documents an update to the 1978 Section 208 Plan for Cape Cod. In a January 30, 2013 letter (See Appendix A), the Massachusetts Department of Environmental Protection (MassDEP) directed the Cape Cod Commission to prepare an update to the 1978 WQM Plan for Cape Cod to address the degradation of Cape Cod's water resources from excessive nutrients, primarily nitrogen.

Accompanying the directive was a commitment to provide the Cape Cod Commission with $3,350,000 from the Massachusetts Water Pollution Abatement Trust to fund the update. The Memorandum of Understanding, dated March 21, 2013 (See Appendix B) between the Massachusetts Water Pollution Abatement Trust (Trust), MassDEP and Barnstable County, acting by and through the Commission, stipulates roles, responsibilities, terms and conditions under which the Section 208 Plan Update was completed.

Introduction

After review and acceptance of a detailed budget and work plan, the Trust and MassDEP provided a notice to proceed on the full Section 208 Plan Update on May 7, 2013 (See Appendix C).

The Cape Cod Commission was given 12 months to submit a draft Section 208 Plan Update to MassDEP and the United States Environmental Protection Agency (US EPA), which was fulfilled in June 2014. A 60-day review period was provided to the agencies and a public draft was released in August 2014 for an extensive 90-day public comment period. All of the comments received, along with responses prepared by the Commission, can be found in Appendix D.

Authority

The Cape Cod Commission is, pursuant to the Cape Cod Commission Act (See Appendix E), the regional planning agency for Barnstable County. The Commission is charged with furthering "the conservation and preservation of natural undeveloped areas, wildlife, flora and habitats for endangered species; the preservation of coastal resources including aquaculture; the protection of groundwater, surface water and ocean water quality, as well as the other natural resources of Cape Cod; balanced economic growth; the provision of adequate capital facilities, including transportation, water supply, and solid, sanitary and hazardous waste disposal facilities; the coordination of the provision of adequate capital facilities with the achievement of other goals; the development of an adequate supply of fair affordable housing; and the preservation of historical, cultural, archaeological, architectural, and recreational values."

The purposes and provisions of the Cape Cod Commission Act require that the Commission "anticipate, guide and coordinate the rate and location of development with the capital facilities necessary to support such development;" therefore, the Commission has the power "to establish a process and procedures for siting and developing capital facilities and developments of regional impact which are necessary to ensure balanced growth."

The Cape Cod Commission was created by an act of the Massachusetts Legislature and ratified by the voters of Barnstable County in 1990 in response to the rapid development pressure of the 1980s. The increased pace of development focused attention on the need to manage growth, guide land use, promote balanced economic growth, provide for adequate capital facilities and infrastructure, and protect environmental resources. The Commission has planning, technical and regulatory tools that can be applied to water quality management on Cape Cod. The Commission has independent statutory authority and is a department within the structure of Barnstable County government. The Cape Cod Commission is also the State-designated area wide water quality management planning agency for Barnstable County.

In 1985 the United States Environmental Protection Agency promulgated regulations (40 C.F.R. §130.6) to provide for WQM planning programs, which

"consist of initial plans produced in accordance with §208 and §303(e) of the [Clean Water] Act and certified and approved updates to those plans." As stated in 40 C.F.R. §130.6(e), a State is authorized to update these WQM plans "as needed to reflect changing water quality conditions, results of implementation actions, new requirements or to remove conditions in prior conditional or partial plan approvals."

As described above, the Commonwealth exerted its authority under Section 208 of the Clean Water Act and 40 C.F.R. §130.6 to designate an agency and require an update to address the critical need for nutrient remediation in Cape Cod water bodies by designating the Commission as the responsible agency and directing the Commission to update the 1978 Section 208 Plan in 2013.

The 1978 Section 208 Plan

The 1978 Section 208 WQM Plan (1978 Plan) for Cape Cod described the major water quality and wastewater management problems confronting the region and recommended land use controls, wastewater management, nonpoint source controls and institutional arrangements to improve water quality.

Specifically, the plan identified increasing residential densities and a three-fold summer population influx as the cause of isolated water quality and wastewater management problems. It anticipated that future growth, primarily in more inland areas where most public water supply wells are located and along the shores of the Cape's many inland ponds, threatened to cause more serious groundwater contamination and increased eutrophication of surface waters.

The emphasis of the 1978 Plan recommendations was on providing for the protection of drinking water quality and quantity. The plan recommended that towns establish protective overlay districts for major "Water Resource Protection Areas," within which residential density would be limited and major polluting uses would be prohibited in order to protect groundwater, surface waters, and coastal waters. It was suggested that the most highly protected areas be those that contribute recharge to public drinking water supply wells. Additionally, it was recommended that towns cooperate in regional water supply planning to encourage water supply self-sufficiency and to develop and implement appropriate protection measures.

The 1978 Plan generally concluded that septic systems that comply with Title 5 of the Massachusetts Environmental Code (310 C.M.R 15.00) were an adequate form of wastewater disposal for the Cape's development. At the time, about 90% of the Cape's year round population relied on on-site septic systems and the plan recommended that the majority of the population could continue to rely on this form of disposal over the 20-year planning period. However, the plan did identify isolated sewer service areas and suggested that the towns of Barnstable, Bourne, Chatham, Falmouth, Provincetown,

and Sandwich proceed with Clean Water Act §201 facilities planning and construction to remediate water quality or other Title 5 related issues within their communities.

To accommodate the majority of development that would remain connected to on-site disposal systems, the 1978 Plan recommended that all towns participate in an effort to regionalize septage treatment and disposal, as well as develop on-site system management programs to ensure proper maintenance and strict enforcement of Title 5, including the upgrading of failing systems and proper installation practices supervised by qualified local health agents (CCPEDC 1978).

Environmental Conditions Requiring an Update

Nitrogen enters marine ecosystems from many different sources. For the purpose of this report they are classified as uncontrollable sources, such as the atmospheric deposition of nitrogen, and controllable sources, such as wastewater, fertilizer and stormwater. This update focuses on nitrogen loads from controllable sources. The uncontrollable loads are accounted for in the calculation of the nitrogen capacity for a given waterbody.

Cumulative concentrations of nitrogen in groundwater, which are substantially lower than drinking water standards, have a significant impact on coastal resources. These impacts are due to the incomplete removal of nitrogen from on-site Title 5 septic systems that were found to be adequate for drinking water protection in the 1978 Section 208 Plan.

Since the 1978 Plan was developed, Cape Cod communities have worked closely with Barnstable County, the Commonwealth, and the Massachusetts Estuaries Project (MEP) to identify the causes and degree of impairment in coastal water bodies. Cape Cod knows more now about the sources of coastal water quality degradation, and potential solutions, than was understood in 1978.

Cape Cod's water resources drive the regional economy. They attract visitors in the summer months and make the Cape a desirable place to live for year-round and seasonal residents. Continuing and increasing nitrogen loading of Cape Cod's embayment watersheds will further degrade coastal water quality, adversely impacting environmental, economic, and societal norms. The economic impact of doing nothing to restore coastal water quality will be significant, affecting every home owner in the region.

Cape Cod has recently been the subject of a lawsuit on this issue. The original lawsuit, filed by the Conservation Law Foundation (CLF) against US EPA, asserts that US EPA violated the Clean Water Act and its regulations by failing to regulate nonpoint sources of nitrogen which have degraded the embayments in a manner that has injured the recreational, commercial and aesthetic interests in those waters. This lawsuit was dismissed for lack of standing.

In a refiled suit, CLF has asserted that the US EPA's mandatory annual review of how Massachusetts administers its State Revolving Fund (SRF) has been contrary to law. Specifically, under the Clean Water Act, the US EPA has the authority to grant money to a state's SRF fund for certain types of wastewater management projects subject to certain restrictions on the use of the funds. The US EPA has a duty to review a state's plans and reports concerning the state's use of those funds on an annual basis.

CLF sought an injunction requiring that (1) the US EPA notify the Commonwealth of its noncompliance; and (2) an update to the Section 208 Area Wide Water Quality Management Plan be completed within one year. The US EPA sought and received a stay of this lawsuit until June 1, 2015, pending review and approval of this updated Section 208 Plan.

In November 2014, CLF and US EPA filed a settlement agreement in US District Court requesting an extension of the existing stay of the Section 208 Action from June 1, 2015 to September 15, 2015, a stay of the TMDL Action until September 15, 2015, and a dismissal of both actions upon completion of a series of actions to be completed by US EPA, including the approval of the Cape Cod Section 208 Plan Update.

The time for Cape Cod communities to act is now. Approval of the Cape Cod Section 208 Plan Update by US EPA and implementation of the principles and recommendations set forth will ensure local control over selection and application of technologies and management of water resources into the future.

A New Approach

THE SECTION 208 PLAN UPDATE – PURPOSE, GOALS, AND PROCESS

PURPOSE

The purpose of the Section 208 Plan Update was to develop an integrated water and wastewater management system that includes a series of phased approaches to remediate groundwater and surface water impairments in each watershed.

GOALS

The goals of the Section 208 Plan Update include:

- To provide an unbiased evaluation of technologies and approaches that may be appropriate in each watershed;
- To promote the use of sustainability criteria in decision making;
- To work with State and Federal partners on regulatory changes necessary to implement adaptive management plans, including the permitting of alternative approaches and appropriate enforcement mechanisms;

- To develop cost effective management strategies for implementing pilot projects, targeted watershed plans, and watershed plans for shared infrastructure; and
- To identify ways to measure and control unanticipated growth made possible through the development of wastewater infrastructure.

PROCESS

The process used in this update is watershed-based, includes a focus on both stakeholder engagement and technical evaluation, seeks to maximize the benefits of local planning, considers the full range of traditional and non-traditional strategies, and favors allowing local stakeholders to decide which of a range of options to pursue, instead of mandating a single "optimal" solution. Affordability and ancillary benefits to Cape Cod's economy and society are considered in the proposed range of approaches.

Overcoming these significant challenges to restoring many of Cape Cod's marine ecosystems requires a new approach. The Section 208 Plan Update reflects a new approach with five basic principles.

1. The plan is watershed based. The most effective and efficient solutions are found by beginning with the consideration of solutions within the jurisdiction of the problem.
2. The plan leverages existing local plans by making use of the enormous amount of data and input already collected by Towns as part of their comprehensive wastewater management planning to date.
3. All solutions are considered – everything has to be on the table. The plan takes into account all technologies and strategies that may be successful on Cape Cod. It evaluates each individually and then looks for appropriate places for its use as part of a watershed scenario.
4. The purpose of the plan is to set the parameters for the discussion of solutions on a watershed basis, and **not** to suggest an optimal solution.
5. Cost must be considered as part of every watershed scenario and the impact on individual homeowners must be a primary concern. If a solution isn't affordable, it isn't doable.

The plan outlines a path forward with recommendations for implementation. The recommendations can be organized into four categories: information, regulatory reform, support, and cost. The Plan identifies areas where more information is needed, where more support can be offered, where regulatory reforms are necessary and suggests options for additional financial support.

01 PEOPLE

The Cape Cod Model - People & Process

Section 208 of the Federal Clean Water Act emphasizes public engagement as much as the technical aspects of the regional planning process. The Cape Cod Commission committed to extensive public engagement to bring more voices to the table in order to develop consensus around a range of solutions to solve water quality problems. The public participation and engagement process was Cape-wide and included both subregional and watershed specific working groups. It took advantage of existing teams, such as the Cape Cod Water Protection Collaborative, and created new teams, as necessary, to address the challenges associated with this extensive and time-constrained planning process.

STAKEHOLDER PROCESS

strategies for establishing consensus in a regional planning process

Section 208 of the Federal Clean Water Act emphasizes public engagement as an important part of the regional planning process. The Cape Cod Commission committed to an extensive public engagement process to bring more voices to the table in order to develop consensus around a range of solutions to solve water quality problems.

OBJECTIVE

In order to be successful, the planning process needed to remain objective. The Commission brought in the Consensus Building Institute to provide facilitation in order to build collaboration and agreement among stakeholders.

AFFORDABLE

A basic principle of the Section 208 Plan Update is that cost be considered as part of every watershed solution and the financial impact on individual homeowners be a primary concern.

ON SCHEDULE

To ensure the Section 208 Plan Update stayed on task and was delivered on time the Commission engaged the Cape Cod Water Protection Collaborative Governing Board and created a new Advisory Board. These Boards provided advice on the overall approach, reviewing draft work product and offering insight on decision-making.

FLEXIBLE

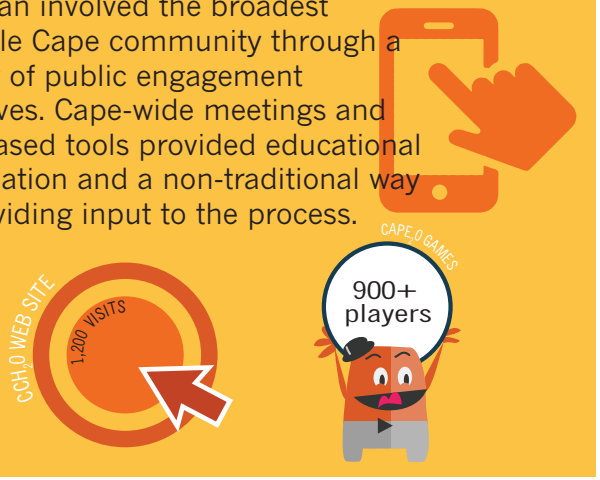
To ensure regulatory flexibility in planning and permitting was addressed, the Regulatory, Legal and Institutional Work Group advised on regulatory reform and increased coordination between local, state and federal regulatory requirements. The Monitoring Committee provided advice on monitoring protocols and a process for monitoring data to inform adaptive management.

AGREEMENT

The Commission built consensus by working across town lines and identifying solutions at the watershed level. A range of stakeholders was convened at the watershed and the subregional level to consider watershed-based solutions and strategies.

ENGAGING

The Plan involved the broadest possible Cape community through a variety of public engagement initiatives. Cape-wide meetings and web based tools provided educational information and a non-traditional way of providing input to the process.



Process Challenges and Solutions

The Cape Cod Commission (Commission) was given 12 months following the receipt of funds associated with the Section 208 Plan Update to provide a draft document to the Massachusetts Department of Environmental Protection (MassDEP) and the United States Environmental Protection Agency (US EPA). The draft document needed input from individuals Cape-wide in order to address regional concerns and develop consensus around solutions. The challenges associated with the complexity of the task and the short time frame required efficient and effective strategies. The Section 208 Plan Update utilized existing organizations and created new boards and committees (see **Figure 1-1** on following page) to work toward developing solutions to these challenges.

CHALLENGE: HOW TO ENSURE PROCESS OBJECTIVITY

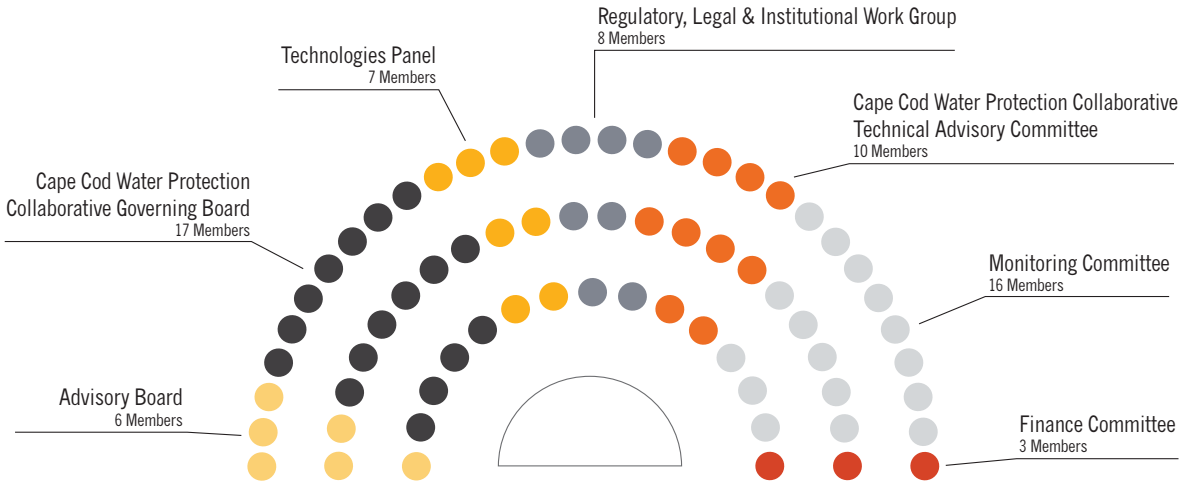
A plan that would address the needs of the region and represent the communities' specific watershed goals and solutions required input from a range of stakeholders with a range of opinions and ideas. In order to be successful, the planning process needed to remain objective.

The Consensus Building Institute (CBI) of Cambridge, MA is an experienced not-for-profit organization focused on negotiation and dispute resolution. As third-party facilitators they work to build collaboration and agreement in complex environments.

The Commission brought CBI on to the project to provide guidance on developing a process for engaging communities in a discussion around watershed impairments and appropriate solutions. Its staff provided third-party facilitation at the watershed, subregional and Cape-wide levels to ensure that all stakeholders were given opportunities to participate and that the Commission effectively responded to concerns and incorporated feedback throughout the process. CBI held all parties involved to a high standard of communication and cooperation in addressing this difficult issue.

Challenges Requiring Solutions

- ☑ Ensuring Objectivity
- ☑ Staying on Task and on Time
- ☑ Reaching Agreement
- ☑ Addressing Affordability
- ☑ Creating Pathway for Regulatory Flexibility
- ☑ Engaging the Broader Public



Section 208 Plan Update Committee Membership

Figure 1-1

CHALLENGE: HOW TO STAY ON TASK AND ON TIME

To ensure the Section 208 Plan Update stayed on task and was delivered on time the Commission engaged an existing team, the Cape Cod Water Protection Collaborative (Collaborative) Governing Board, and a new team, the Section 208 Plan Update Advisory Board.

COLLABORATIVE GOVERNING BOARD

The Collaborative was created by county ordinance in 2005 and exists to offer a coordinated approach to enhance the water and wastewater management efforts of towns, the regional government and the broader community. The Collaborative seeks to protect Cape Cod's shared water resources and provide access to cost-effective and environmentally-sound wastewater infrastructure. The Collaborative seeks funding support for Cape communities, establishes priorities, directs strategy, builds support for action and fosters regionalism.

The Collaborative Governing Board reinstated monthly meetings in May 2013 to follow the Section 208 Plan Update process from start to finish. The Governing Board's 17-members approve all expenditures, policies and strategies of the Collaborative. Membership consists of an appointed member from each town (typically a Selectmen or staff member) in addition to two County Commissioners' appointees. Monthly updates were provided to the Board, which was given a chance to comment and provide feedback. See Appendix 1A for a list of members and their affiliations, as well as meeting information.

208 PLAN UPDATE ADVISORY BOARD

A six-person Advisory Board met monthly and was convened with subregional representation and ad hoc members with regional points of view and experience. Members had current or prior experience in municipal government and/or experience with other regional-scale issues, such as groundwater cleanup at Joint Base Cape Cod and regionalizing school districts.

The mission of the board was to support the Section 208 planning process by providing advice on the overall approach, reviewing draft work product and offering insight on strategic and tactical decision-making. See Appendix 1B for a list of members and their affiliations, as well as meeting information.

CHALLENGE: HOW TO COME TO AGREEMENT ON SOLUTIONS

At the outset, the Commission sought to build community consensus across town lines and identify solutions within the jurisdiction of the problem - watersheds. The most effective and efficient solutions are found by beginning consideration of solutions at this level.

To begin this effort, a chronology of municipal planning efforts was developed for each town. It established what had been done, identified successes and failures to date, and began to illustrate the overlap between communities planning in each watershed. More detail on town planning efforts can be found in Chapter 2.

A premise of the Section 208 planning process is that all solutions must be on the table. The plan takes into account all technologies and strategies that may be successful on Cape Cod, evaluates each individually and looks for appropriate places for use as part of a watershed scenario. The purpose of watershed scenarios is to set parameters for the discussion of solutions on a watershed basis. The watershed scenarios developed represent a range of possible options. They do not suggest an optimal solution, as decisions on how to proceed must be made locally.

To determine appropriate technologies to consider and build consensus on approaches to watershed planning across town boundaries an existing team – the Technical Advisory Committee (TAC) of the Collaborative - and several new teams - the 208 Plan Update Technologies Panel, watershed working groups, and subregional working groups - were utilized.

COLLABORATIVE TAC

The TAC was re-formed and re-chartered to look at some of the technical aspects of the Section 208 Plan Update. Specifically, the TAC reviewed and commented on the suite of technologies identified through the Water Quality Technologies Matrix (Technologies Matrix) and helped to develop and refine a series of one-page fact sheets for stakeholders and community use. These have been incorporated in the online Technologies Matrix, available at: http://capecodcommission.org/matrix. The TAC consists of one appointed representative from each town and a MassDEP representative to provide the regulatory, permitting and technical perspectives. See Appendix 1C for a list of members and their affiliations.

TECHNOLOGIES PANEL

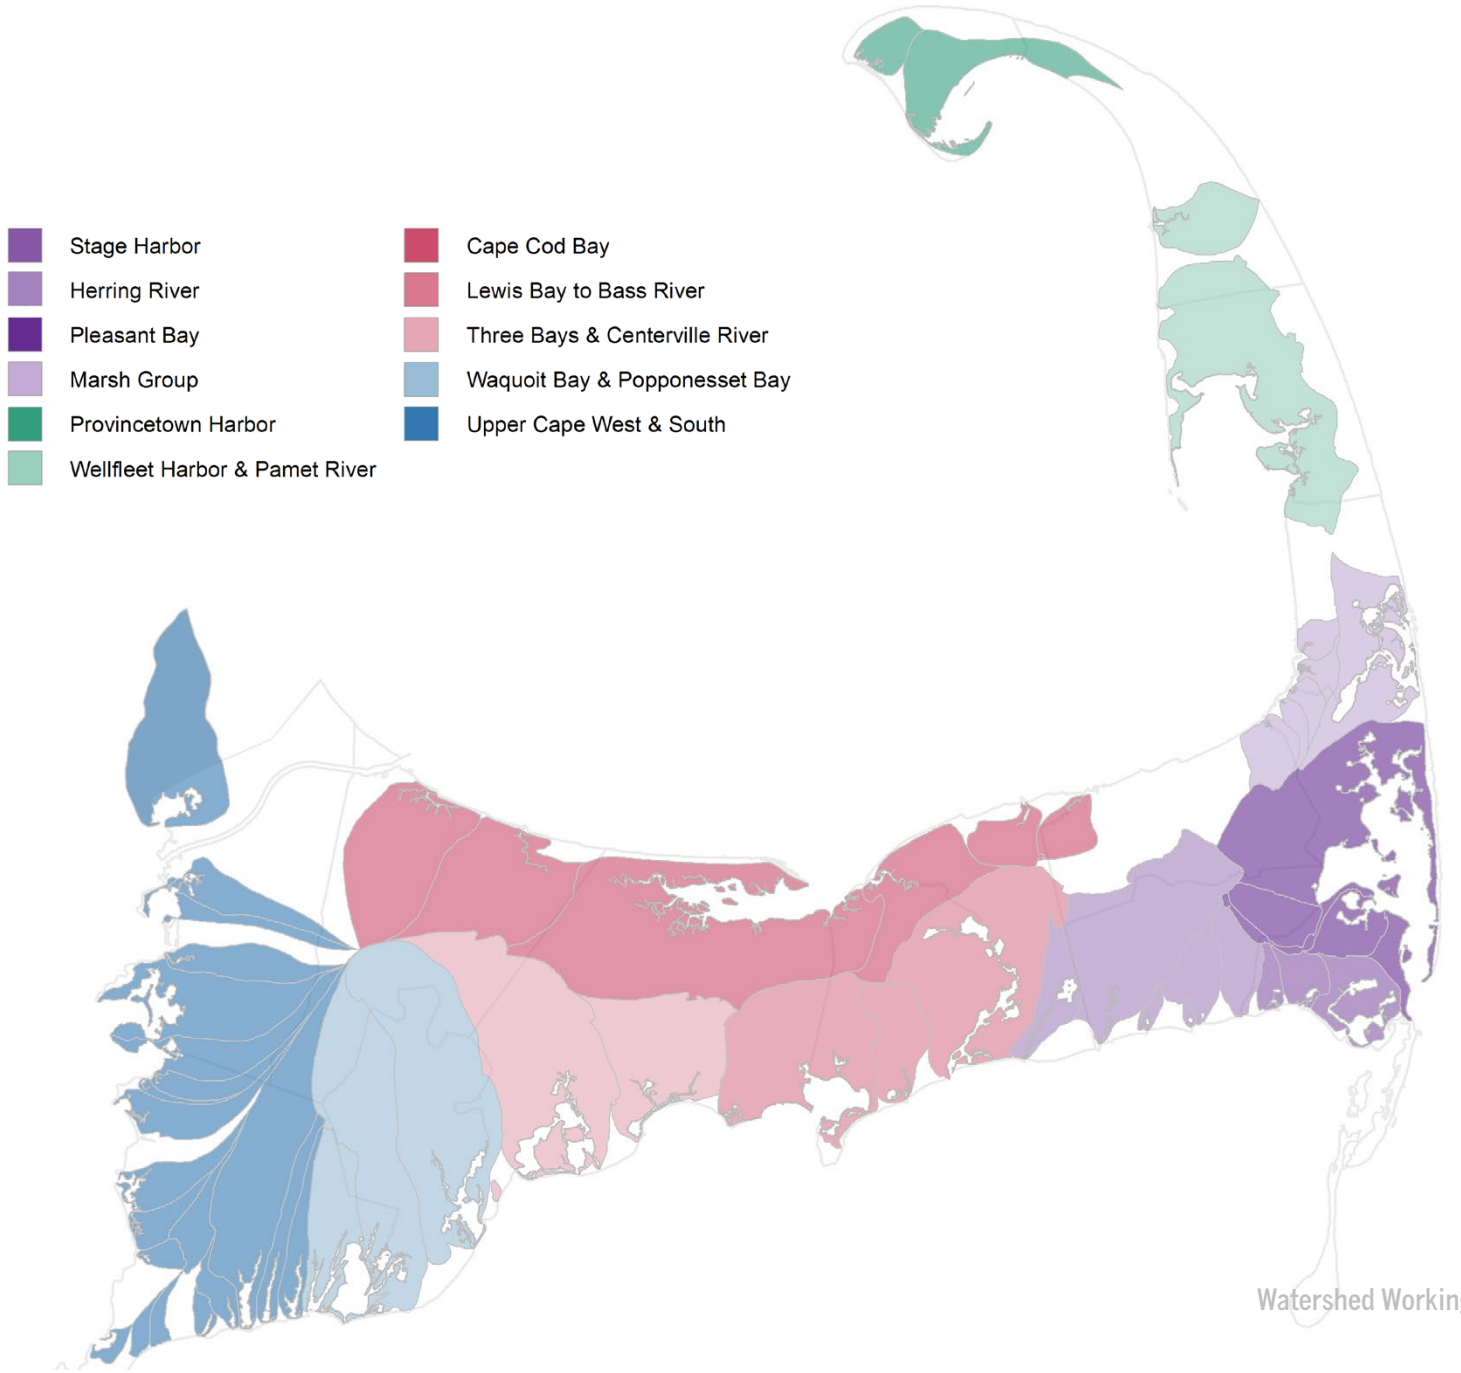
A Technologies Panel, which met four times over the course of two months, was convened to review, confirm, and expand upon the Technologies Matrix, review the overall planning approach in each watershed, and provide input on a site-screening methodology for non-traditional technologies. The panel consisted of local, national, and international experts on the impact of nutrients in coastal waters, remediation approaches, and emerging technologies. See Appendix 1D for a list of members and their affiliations, as well as meeting information.

STAKEHOLDER ENGAGEMENT

For the purposes of planning, the 53 embayment watersheds across Cape Cod were grouped into 11 watershed working groups based on proximity to one another, level of impairment and other hydrogeologic characteristics (see **Figure 1-2** on following page).

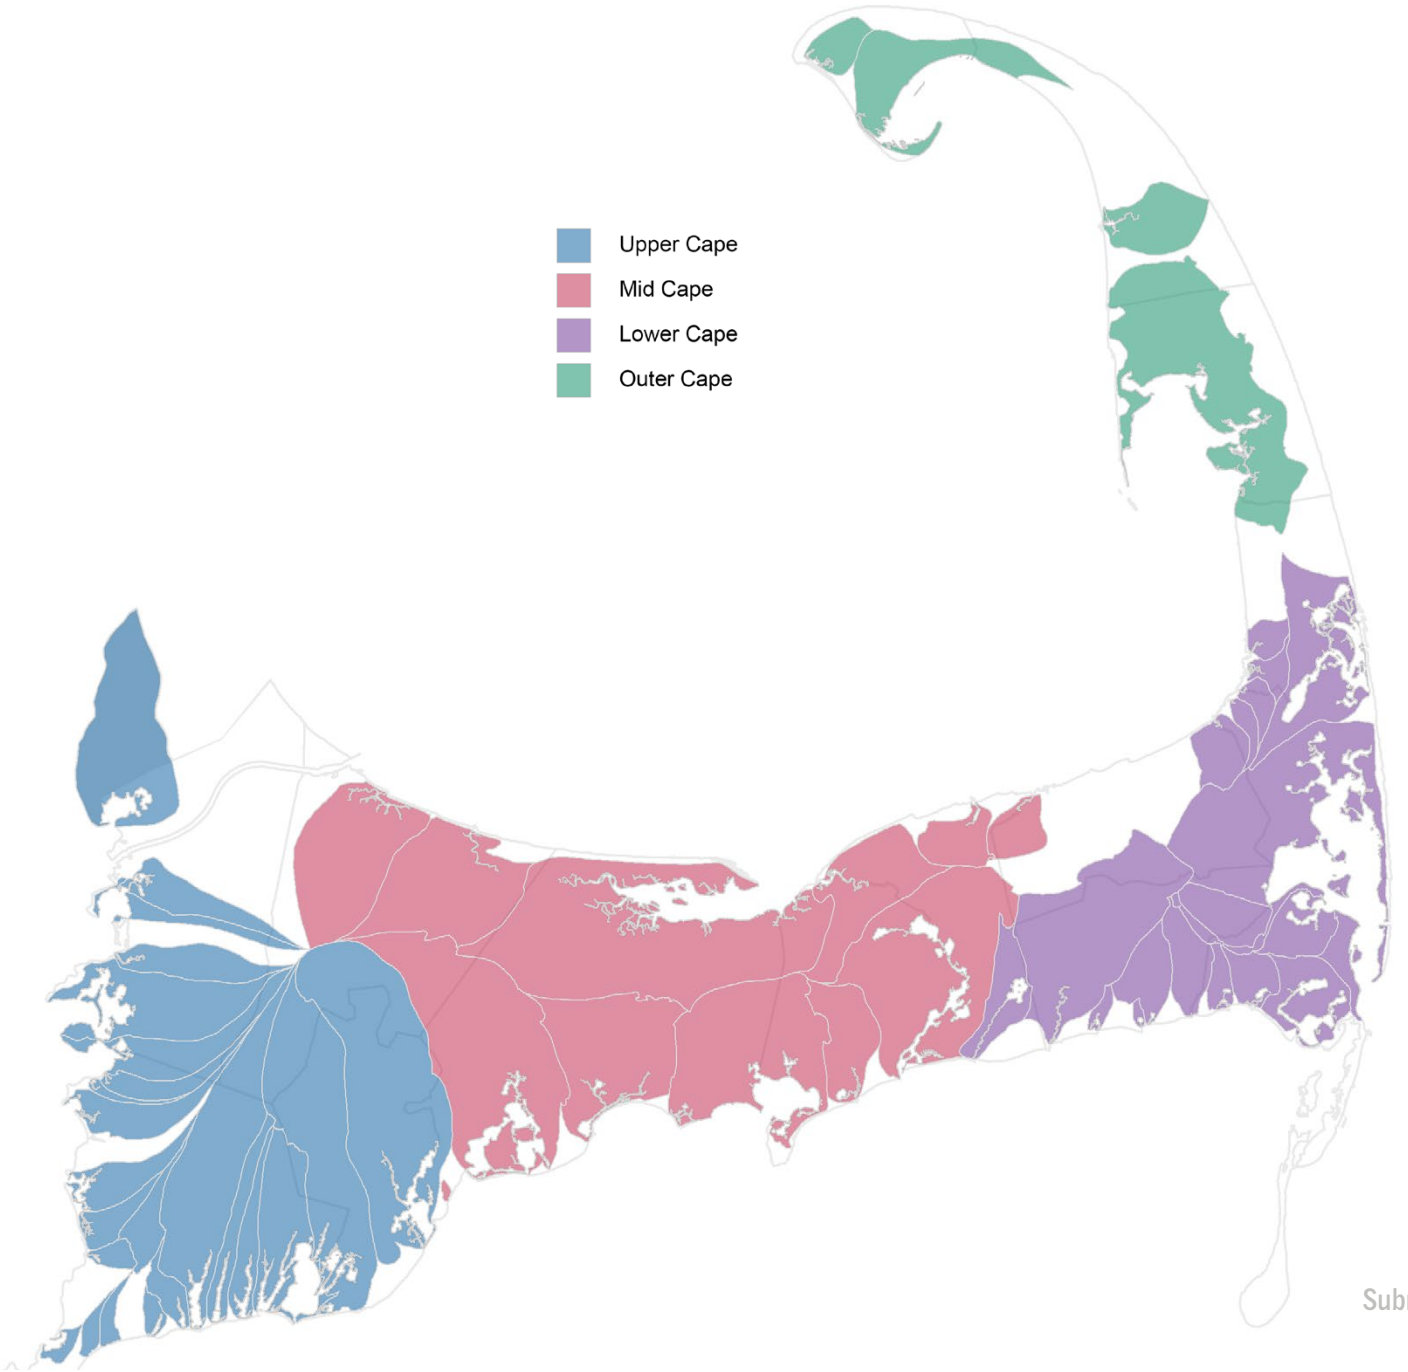
Consistent with the iterative process used throughout development of the Section 208 Plan, the number of watersheds considered in the final plan was reduced from 57 to 53. Four small watersheds are now accounted for within the broader watershed areas to which they contribute.

The watersheds were further organized in to four subregional working groups – the Upper Cape, Mid Cape, Lower Cape, and Outer Cape (see **Figure 1-3** on following page).



Watershed Working Group Boundaries

Figure 1-2



Subregional Boundaries

Figure 1-3

Everyone on Cape Cod is connected in some way to these watersheds. The embayment watersheds make up approximately 79% of the land area on Cape Cod (**Figure 1-4**) and are home to 89% of its residential development and 78% of non-residential development.

Each watershed can be categorized by level of impairment. The scale and diversity of the planning area warranted an extensive and varied group of stakeholders to provide input. **Figure 1-5** shows the watersheds included in each subregion and watershed group along with the general degree of impairment.

Working Groups, made up of 15-20 self-selected stakeholders (about 170 people Cape-wide), are associated with each watershed working group. Each group consists of the following general representation:

- Local Elected Officials
- Wastewater Committee Members
- Town Professional Staff
- Local Business Owners/Operators
- Local Environmental Organizations
- Civic Group Members
- Alternative Technology Interests
- Development/Real Estate Community
- Interested/Concerned Citizens

To start the stakeholder process, two meetings were held in each of the four subregions – one in July 2013 to introduce the process and develop the watershed working groups and one in August 2013 to introduce information around affordability of infrastructure and discuss what residents and business owners on Cape Cod are currently paying for water and wastewater infrastructure. These meetings helped engage communities and identify stakeholders interested in participating in the process.

See Appendix 1E for a full list of the planning areas and the watersheds included in each, as well as the stakeholder group associated with each.

WATERSHED WORKING GROUPS

Each watershed working group met three times in four-hour-long professionally-facilitated meetings in the fall of 2013 - once in September to discuss the baseline information in each of their watersheds, including land use, nitrogen related water quality impairments, pond water quality, existing infrastructure, and proposed infrastructure identified through previous municipal efforts, once in October to discuss the range of technologies and approaches that might be used on Cape Cod, and once in December to discuss the process for applying technologies and approaches in each watershed. See Appendix 1F for a complete list of meeting dates, agendas, and meeting summaries for all of the watershed working group meetings.

SUBREGIONAL WORKING GROUPS

Following the three sets of watershed working group meetings the conversation shifted from discussing the jurisdiction of the problem, at the watershed level, to the jurisdiction of the solution, at the subregional level. In February 2014, the watershed working groups were asked to self-select into subregional working groups, with representation from each of the established categories.

The structure of the subregional meetings was different from the watershed working group meetings, which had discrete topics associated with each. The subregional meetings were iterative, with a standing agenda that included scenario planning, regulatory, legal and institutional issues, and implementation. Meetings included representation from MassDEP and US EPA and were also professionally facilitated by CBI.

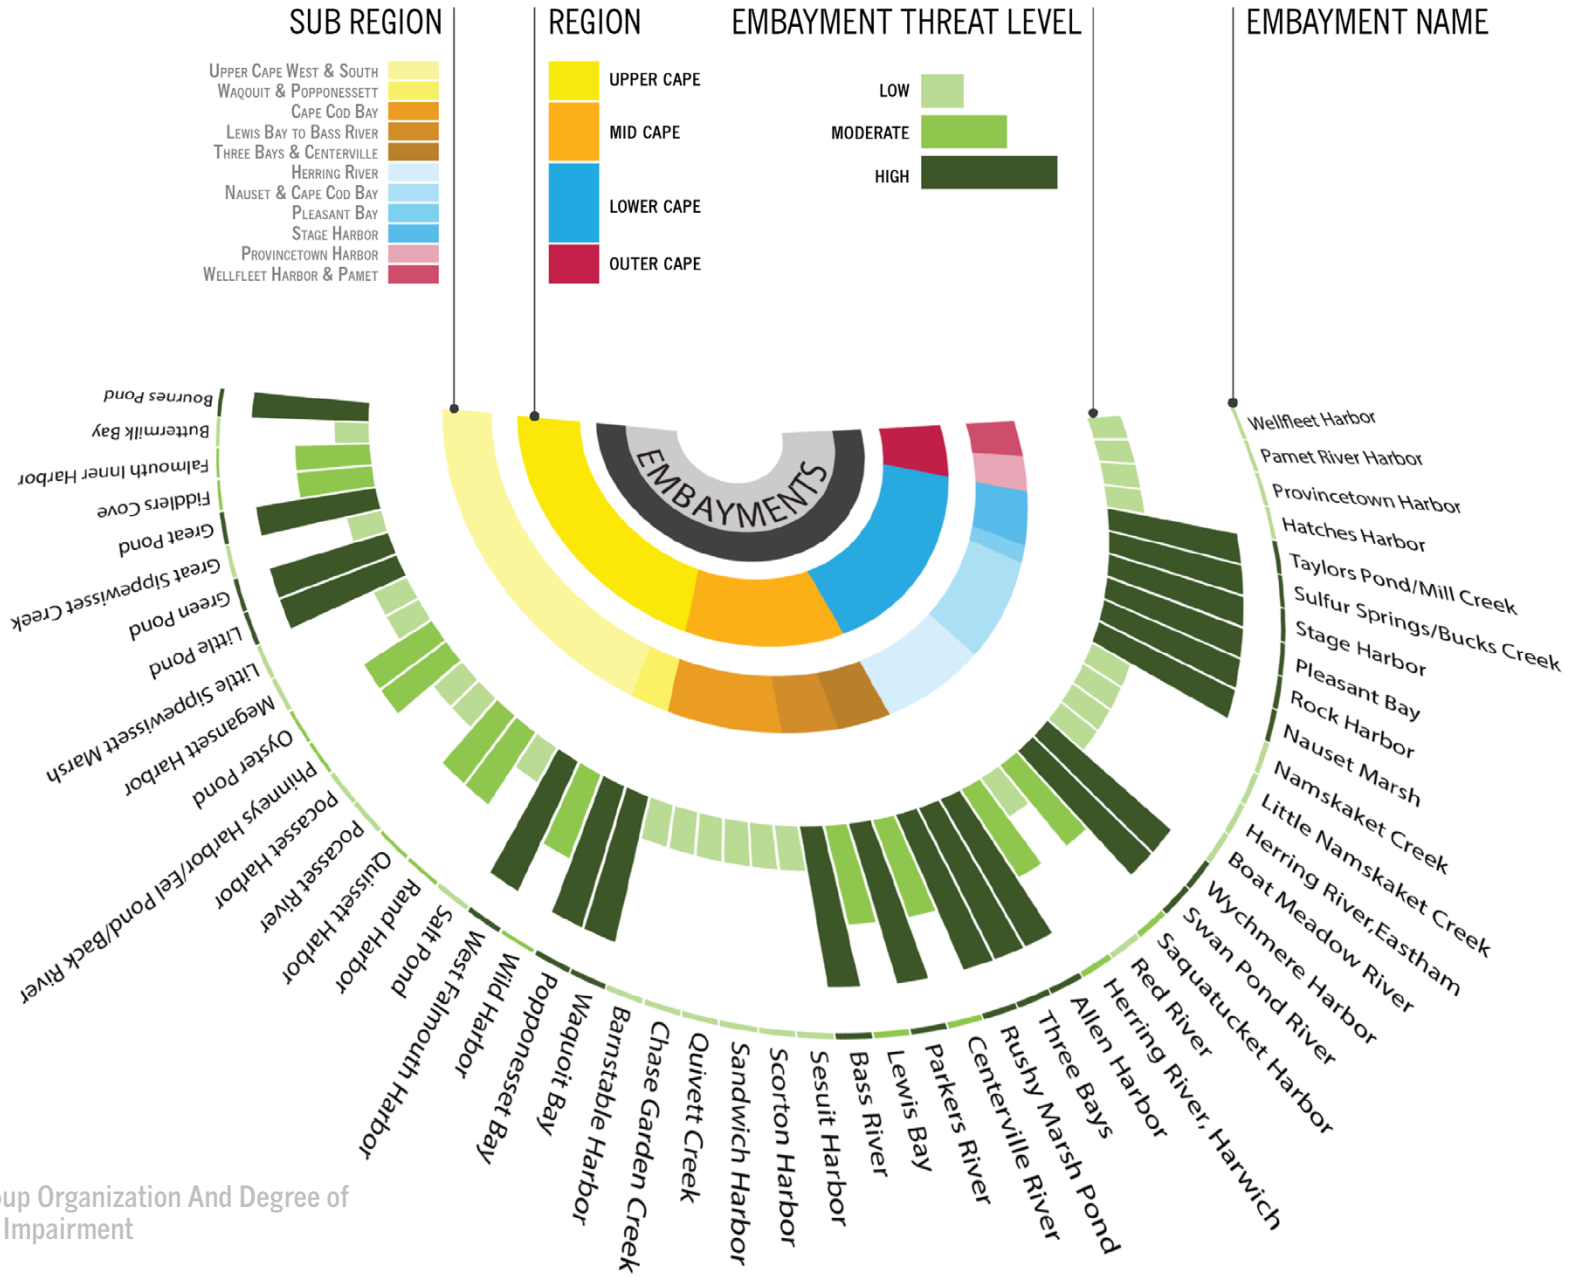
Figure 1-4



Working Group Organization And Degree of Embayment Impairment

Figure 1-5

See Appendix 1G for a complete list of meeting dates, agendas, and meeting summaries for all of the subregional meetings.

CHALLENGE: HOW TO ADDRESS THE ISSUE OF AFFORDABILITY

One of the basic principles of the Section 208 Plan Update is that cost be considered as part of every watershed solution and the impact on individual homeowners be a primary concern. If a solution isn't affordable, it's not doable.

In addition to identifying more affordable technologies, it is of the utmost importance to consider how to pay for the needed solutions and identify new resources from the State and Federal Governments to offset the costs.

To help achieve the goals of ensuring affordability for Cape Cod residents and businesses, considering innovative ways to pay for solutions and identifying new resources the Commission established a new team – the 208 Plan Update Finance Committee.

FINANCE COMMITTEE

The Finance Committee met monthly and was convened with representation from local communities and support from consultants to the Cape Cod Commission. Members included a town administrator, a finance director, and a municipal finance committee member. The mission of the committee was to work with the consultants to the Commission to establish a factual basis for discussing issues of affordability, financing, and resources related to the Section 208 Plan Update. See Appendix 1H for a list of members and their affiliations, as well as meeting information.

CHALLENGE: HOW TO ADDRESS THE NEED FOR REGULATORY FLEXIBILITY

The existing regulatory framework was built to solve other problems. Existing regulatory drivers overbuild expensive solutions dependent on pointsource technologies to solve a nonpoint source problem. This approach doesn't account for the unique challenges of Cape Cod as a coastal community with a marine water quality issue caused by nutrients and a relatively low-density development pattern.

To ensure regulatory impediments and flexibility in planning and permitting were addressed the Commission established two new teams – the Section 208 Plan Update Regulatory, Legal and Institutional Work Group (RLI) and the Monitoring Committee.

RLI WORK GROUP

The RLI Work Group had representation from MassDEP, US EPA, the Cape Cod Commission, and other State and Federal partners, as necessary. It addressed the potential need for regulatory reform and other challenges associated with planning and implementation. The need for increased coordination between local, state and federal regulatory requirements was identified by the Commission and the group met monthly to discuss this and other opportunities and challenges related to the Section 208 Plan Update. See Appendix 1I for a list of RLI Work Group members and their affiliations, in addition to meeting information.

MONITORING COMMITTEE

The Monitoring Committee was convened in April 2014 and continues to meet monthly. The mission of the committee is to provide expertise on appropriate monitoring protocols for technology efficiency and total maximum daily loads (TMDLs), while identifying a process for consolidating all available monitoring data in a central location and format. Members include representatives from MassDEP, US EPA, academic institutions, non-profit organizations, and other government agencies. The roles and responsibilities of this committee are to:

- Establish performance monitoring protocols for technologies that may be a part of watershed permits in the future;
- Establish compliance monitoring protocols for meeting TMDLs in the water body;
- Establish a process and structure for consolidating and cooperation of existing monitoring programs and data in to a centralized location; and
- Identify region-wide monitoring needs and develop proposals.

To achieve the benefits of flexible permitting, a plan must remain adaptive in nature. Monitoring the technologies permitted as part of an adaptive management plan is essential to maintaining a flexible regulatory environment

into the future. See Appendix 1J for a list of Monitoring Committee members and their affiliations, as well as meeting information.

CHALLENGE: ENGAGING THE BROADER CAPE COD COMMUNITY

While the number of individuals involved in the effort to update the Section 208 Plan was significant, the broader public still needed to be engaged and educated on water quality issues. In an effort to broaden outreach the Commission developed web-based engagement opportunities and held Cape-wide meetings to provide updates on the problem and process.

WEB-BASED CAPE-WIDE ENGAGEMENT

Cape2O

Between July and December 2013 the Commission ran two online engagement games with the help of the Engagement Game Lab at Emerson College on their Community PlanIt platform (https://communityplanit.org/capecod/). The engagement games, called Cape2O, introduced players to water quality issues on Cape Cod, and touched upon science, civics, economics, our environment and consensus building. The initial game was targeted at seasonal and year-round residents, with the second game targeted at schools. More than 900 individuals registered for the two games, generating more than 6,000 comments and questions on water quality issues. Six local "causes" were awarded $1000 prizes to implement projects on Cape Cod. See Appendix 1K for supporting materials.

www.CCH2O.org

The website www.cch2o.org was developed by the Commission as a portal to raise watershed awareness and enable individuals to better understand various approaches and technologies that may improve water quality on Cape Cod. It was designed to increase the community's understanding of water quality concepts – why water quality problems exist and how they might be improved – through a web-based interactive tool.

Through the website, users are able to locate the watershed in which they live and acquaint themselves with nutrient issues specific to that watershed. The site also provides an opportunity for citizens to examine solutions to water quality problems at individual and community-wide levels. Various links are available to allow users to dig deeper into other web-based tools the Commission has developed and to provide an email address or log in to be updated on the Commission's ongoing efforts.

CAPE-WIDE MEETINGS

On November 13, 2013, the Commission held a Watershed Event to conclude the Cape2O game, award prizes to participants and provide funding to top projects associated with the game. Over 120 stakeholders, Cape2O players, regulatory agency staff, and members of the public attended. Speakers included Cape and Islands Senator Dan Wolf, as well as representatives from the US EPA and MassDEP. In addition to discussing the outcomes of the Cape2O game the time was used to begin the discussion around structuring the second half of the stakeholder engagement process – the subregional working group meetings.

On February 6, 2014, the Commission held a day-long Stakeholder Summit to review the work to date and discuss the path forward toward development of the Section 208 Plan Update. About 270 stakeholders, regulatory agency staff, and members of the public attended the event and speakers included the state treasurer, MassDEP commissioner, CEO of the Cape Cod Chamber of Commerce, representatives from the US EPA and the Cape Cod Commission. The discussion focused on the importance of the community involvement in the Section 208 planning process and the need to meet water quality goals in Cape Cod's estuaries. Breakout sessions included preliminary conversations on scenario planning, regulatory, legal, and institutional issues, and implementation issues, in order to set the stage for the upcoming subregional working group sessions.

See Appendix 1L for all materials related to the Watershed Event and the Stakeholder Summit.

Learning from the Community

Complex environmental problems caused in large part from human interaction with the land and natural environment require complex solutions. Solutions for water quality problems on Cape Cod are not only environmental, but social and political as well. Solving this problem requires cooperation among communities and respect for stakeholder perspectives. Stakeholder feedback maintained that one of the greatest challenges to collaboration in shared watersheds is managing disagreement amongst various interests and multiple municipalities in a shared watershed.

As part of the Section 208 Plan Update, the Commission recommends that guidance on managing disagreement among parties be developed.

> Recommendation S1.1: The Cape Cod Commission shall develop guidance on managing disagreement among parties.

When many people join together to solve a problem, regardless of the approach taken or model used, there will be different points of view and different strategies proposed. Part of the planning effort should include building mechanisms into the process to solve such disagreement.

Each party should conduct a self-assessment as part of the terms of their collaboration with a focus on each party's ability to define responsibilities and annual objectives. Agreeing to alternative dispute resolution mechanisms, whether formal or informal, creates that mechanism for managing disagreement as it arises. Agreement to such processes may keep the content of such mediations the responsibility of parties themselves, encourage the exchange of information, help parties to understand differing views, shift the focus to the future, invent solutions that meet fundamental interests of all parties, and increase public trust. The goal of such a process would be a mutually acceptable settlement of all issues raised.

Barnstable County could be considered as a resource for mediation support services. Barnstable County could designate a liaison in each shared watershed to provide support in working through disagreements. These designees could work with town managers, planners or other boards and working groups as a point of contact and provide facilitation service to towns as they implement watershed plans and approaches.

02 PROBLEM

Cape Cod Baseline - People & Place

Cape Cod's great natural beauty, bountiful recreational opportunities and proximity to major urban areas led to a rapid increase in population over the last half century. The region is defined by, and dependent on, the marine environment that surrounds it. The intersection of the region's hydrology with its year round and seasonal population presents specific challenges. Increased residential development built to accommodate the rapid influx of people to Cape Cod depended almost exclusively on individual septic systems, which discharge nitrogen to the groundwater. There are101 watersheds to the surrounding marine waters and of those, 53 are watersheds to coastal embayment systems. The coastal embayments are located at the margin of the aquifer and are the ultimate receiver of the aquifer's groundwater discharge.

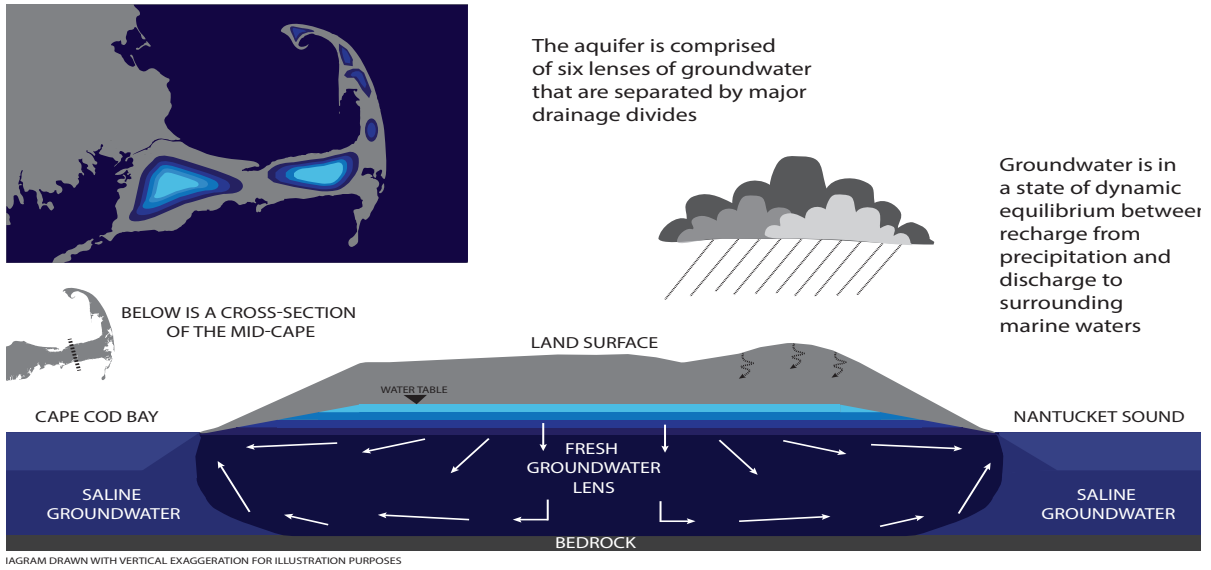
PHYSICAL SETTING: WATER ON CAPE COD

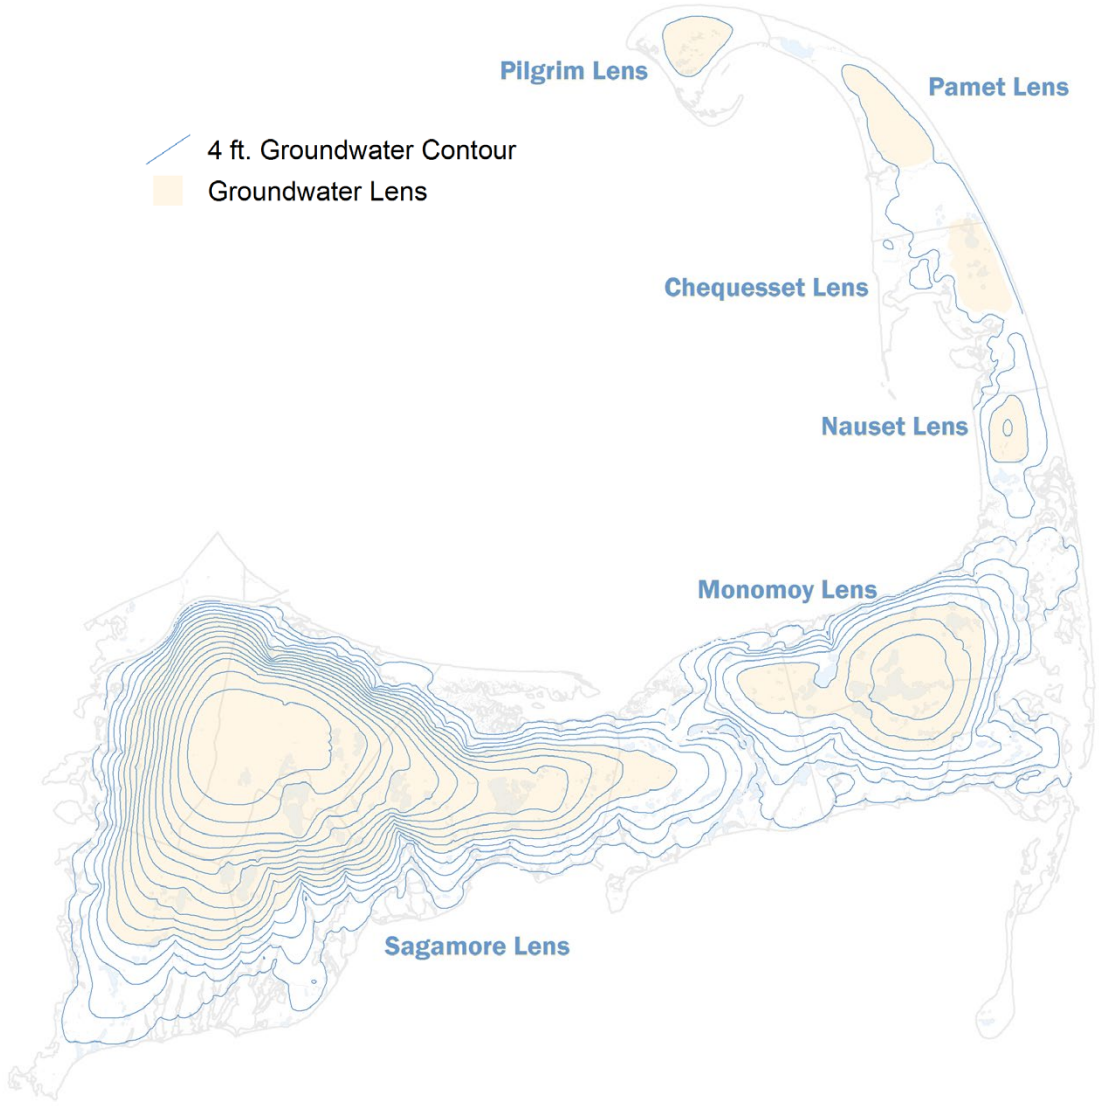
Cape Cod is an iconic peninsula, only 10 miles at its widest point. It is completely surrounded by marine water, including Cape Cod Bay, the Atlantic Ocean, Nantucket Sound, and the Cape Cod Canal. Cape Cod also hosts 996 freshwater ponds covering 11,000 acres of its land area. The fresh water beneath the land is called groundwater.

Cape Cod is a sand and gravel remnant of the last continental deglaciation that occurred 15,000 to 20,000 years ago. The Cape is a series of broad gently sloping outwash plains that are truncated by long linear moraine deposits found along the present day Route 6/Mid-Cape Highway from Sandwich to Orleans and Route 28/ MacArthur Boulevard through Bourne and Falmouth. The glacial deposits are approximately 150 to 900 feet thick from Buzzards Bay to Provincetown and are generally coarse to medium sand, but grade to finer materials at depth. The coarse sands are extremely permeable making for a high yielding groundwater system (**Figure 2-1** illustrates the groundwater system).



Groundwater

Figure 2-1



Water Table Map of Cape Cod

Figure2-2

The groundwater of Cape Cod is bounded at the top by the water table which is ubiquitous across the Cape, a sharp transition zone between fresh and marine water at the shore, and by bedrock below, except for the Outer Cape where freshwater lens floats on top of saltwater.

The groundwater system is recharged solely from precipitation at a rate of 27 inches per year (approximately 60% of precipitation). The groundwater system is in dynamic equilibrium between recharge and discharge to the surrounding marine waters and flows at approximately one foot per day due to gravity. Groundwater located further inland has a greater distance to travel to get to the shore, therefore, the accumulation of recharge over time mounds up. The mounds of groundwater are relatively thin and convex and therefore are referred to as lenses of groundwater.

Six separate lenses comprise the Cape Cod aquifer system: the Sagamore Lens is the groundwater system for the Upper and Mid Cape region, the Monomoy Lens for the Lower Cape and the Nauset, Pamet, Chequesset, and Pilgrim Lens for the Outer Cape. (see **Figure 2-2**).

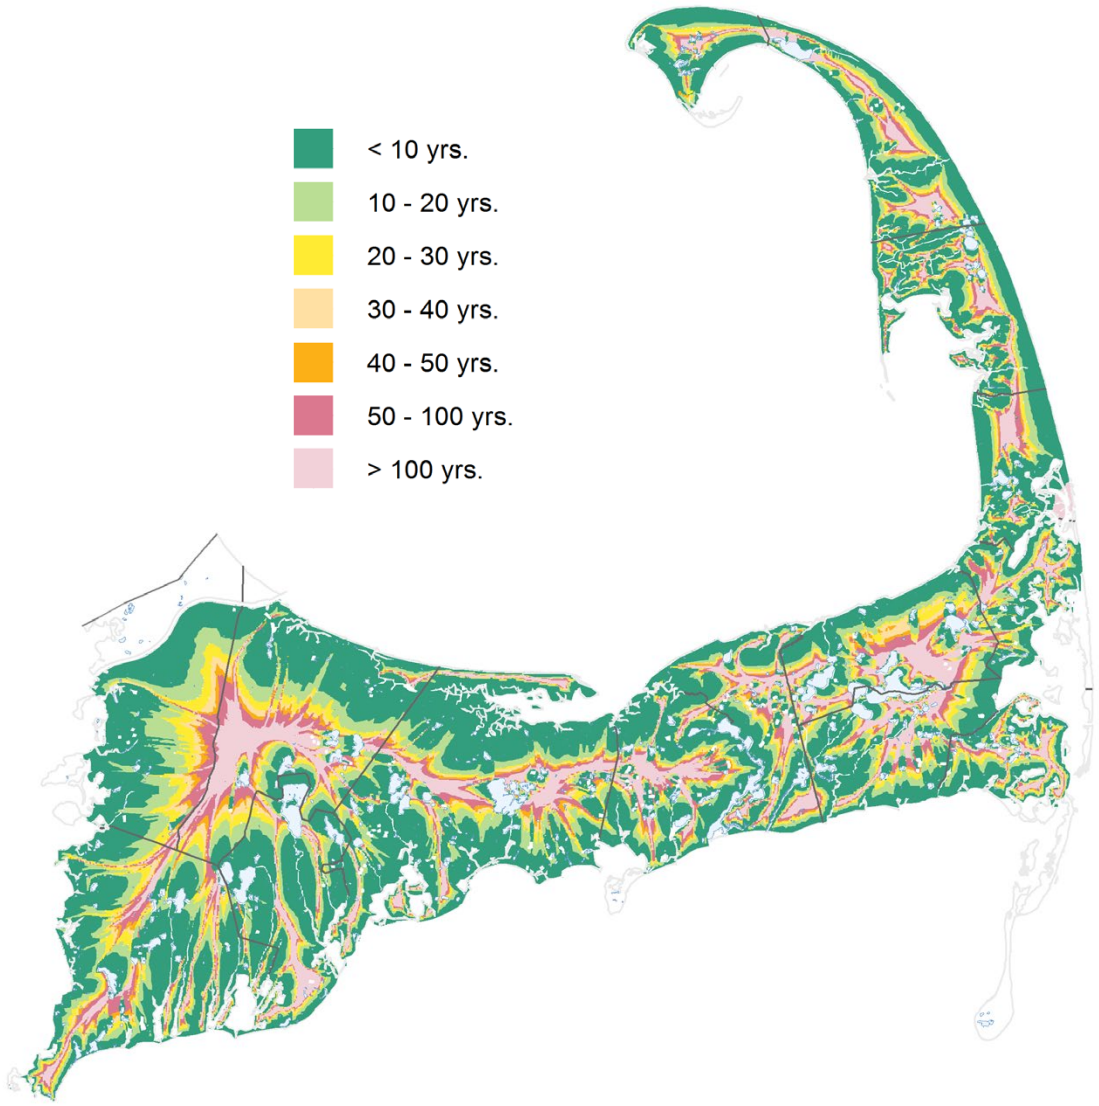
The Cape's groundwater system is directly connected to the fresh and surrounding marine systems. It is susceptible to contamination from various land uses and activities as described in later sections.

Figure 2-3 shows the groundwater time-of-travel areas on Cape Cod, as delineated by the United States Geological Survey (USGS), indicating the years required for a particle to travel from its point of entrance to the groundwater to Cape Cod's coastal embayments.

Travel time is less than 10 years for almost half of Cape Cod's land area. This presents the likelihood that wastewater treatment options, once implemented in these areas, could result in water quality improvements within 5-10 years in some degraded embayments.

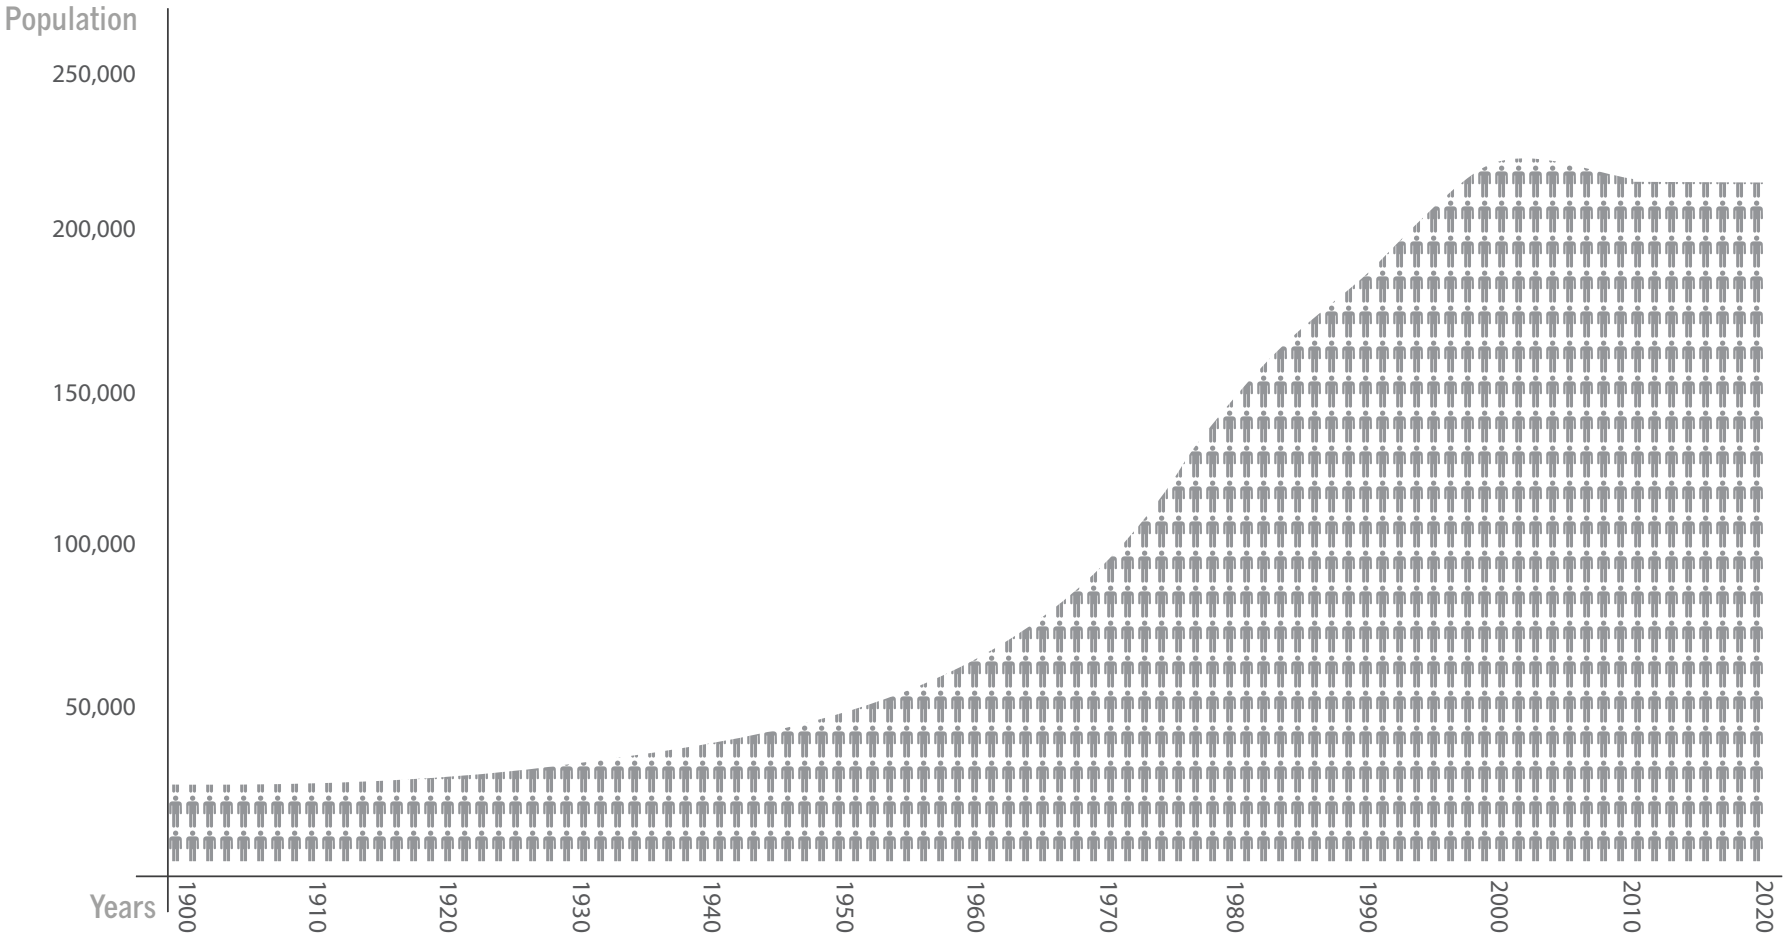
LAND USE: POPULATION, DENSITY, AND SEASONALITY:

Land use on Cape Cod has changed over time due in part to fluctuations in population. The Cape's traditional farming and fishing way of life underwent a slow transformation from the 1870s through the early part of the 20th century as seaside resorts began to attract summer visitors. The advent of rail travel and the adoption of the interstate highway system added to the accessibility and the popularity of Cape Cod.



USGS Time of Travel Map

Figure 2-3



Total Population Barnstable County

Figure 2-4

The population began to rise more quickly in the 1950s and even more steeply from the 1970s through the early 2000s, as Cape Cod became a desired location for retirees and second-home buyers (see **Figure 2-4**).

During this time period, the population of Cape Cod swelled 400%. In 1951, just prior to the swell in population, most of the interior of Cape Cod remained open space and the coasts were developed as dense residential areas. By 2012, the interior of the Cape Cod peninsula was consumed by residential units (**Figure 2-5** through **Figure 2-13**). Recently, population decreased from about 227,000 in 2001 to an estimated 215,000 in 2011. The decline is attributed, in part, to the increasingly high cost of Cape Cod real

estate as the market boomed in the last decades of the 20th century, followed by the swift market decline toward the end of the first decade of the 21st century.

These striking changes in population and land use are also apparent in density patterns on Cape Cod. Based on 2010 Census data, the density of human habitation is 582 people per square mile, nearly five times that in 1950 (118 people per square mile). Furthermore, the density in 2010 is far from uniform; people are clustered together in specific areas on the land surface. There are as few as 36 people per square mile in many protected areas, such as the National Seashore on the Outer Cape, state parks and Wellhead Protection Areas. In highly dense areas, such as Hyannis, there are as many as 4,500 people per square mile. The density of housing units mirrors the non-uniformity of human habitation on Cape Cod. Areas such as Falmouth, Barnstable and Provincetown, have larger numbers of people and more housing units per square mile than other parts of the Cape.

There is a seasonality to the population on Cape Cod. In the past several decades the number of people living year-round on Cape Cod increased, with a corresponding conversion of seasonal homes for year-round use. Approximately one third of the housing stock on Cape Cod (57,000 housing units) is dedicated to seasonal use. Seasonal units are non-uniformly distributed over the land and are much more prevalent in coastal areas than inland areas (**Figure 2-14**).

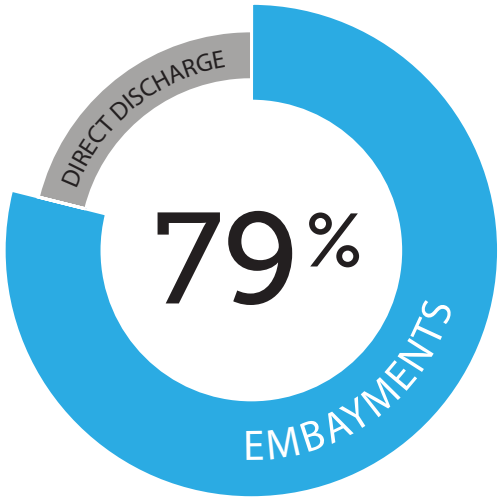
Embayments Watersheds

Figure 2-15

THE INTERSECTION OF PEOPLE AND PLACE

The intersection of the region's hydrology with its year round and seasonal population presents specific nutrient pollution challenges. Increased residential development built to accommodate the rapid influx of people to Cape Cod depended almost exclusively on the construction of individual septic systems. Individual on-site septic systems are documented as the greatest contributing factor to declining estuary and embayment water quality. In the following sections, marine, fresh and ground water systems will be reviewed with specific attention to water quality issues.



Percentage of Cape Cod Land Area that Discharges to an Embayment

Figure 2-16

MARINE WATER

Cape Cod hosts 101 watersheds that drain into surrounding marine waters. A watershed is a geographic area separated from other regions by drainage divides. Within each watershed area, water flows to an embayment or other water body. Fifty-three watersheds on Cape Cod drain into coastal embayment systems. Coastal embayments, partially enclosed coastal areas with varying degrees of tidal restriction, are located at the margin of the aquifer and are the ultimate receiver of the aquifer's groundwater discharge. Embayments are important ecosystems on Cape Cod; they are the primary habitat for shellfish, spawning grounds for fish stocks, and important recreational areas for Cape Cod residents and visitors.

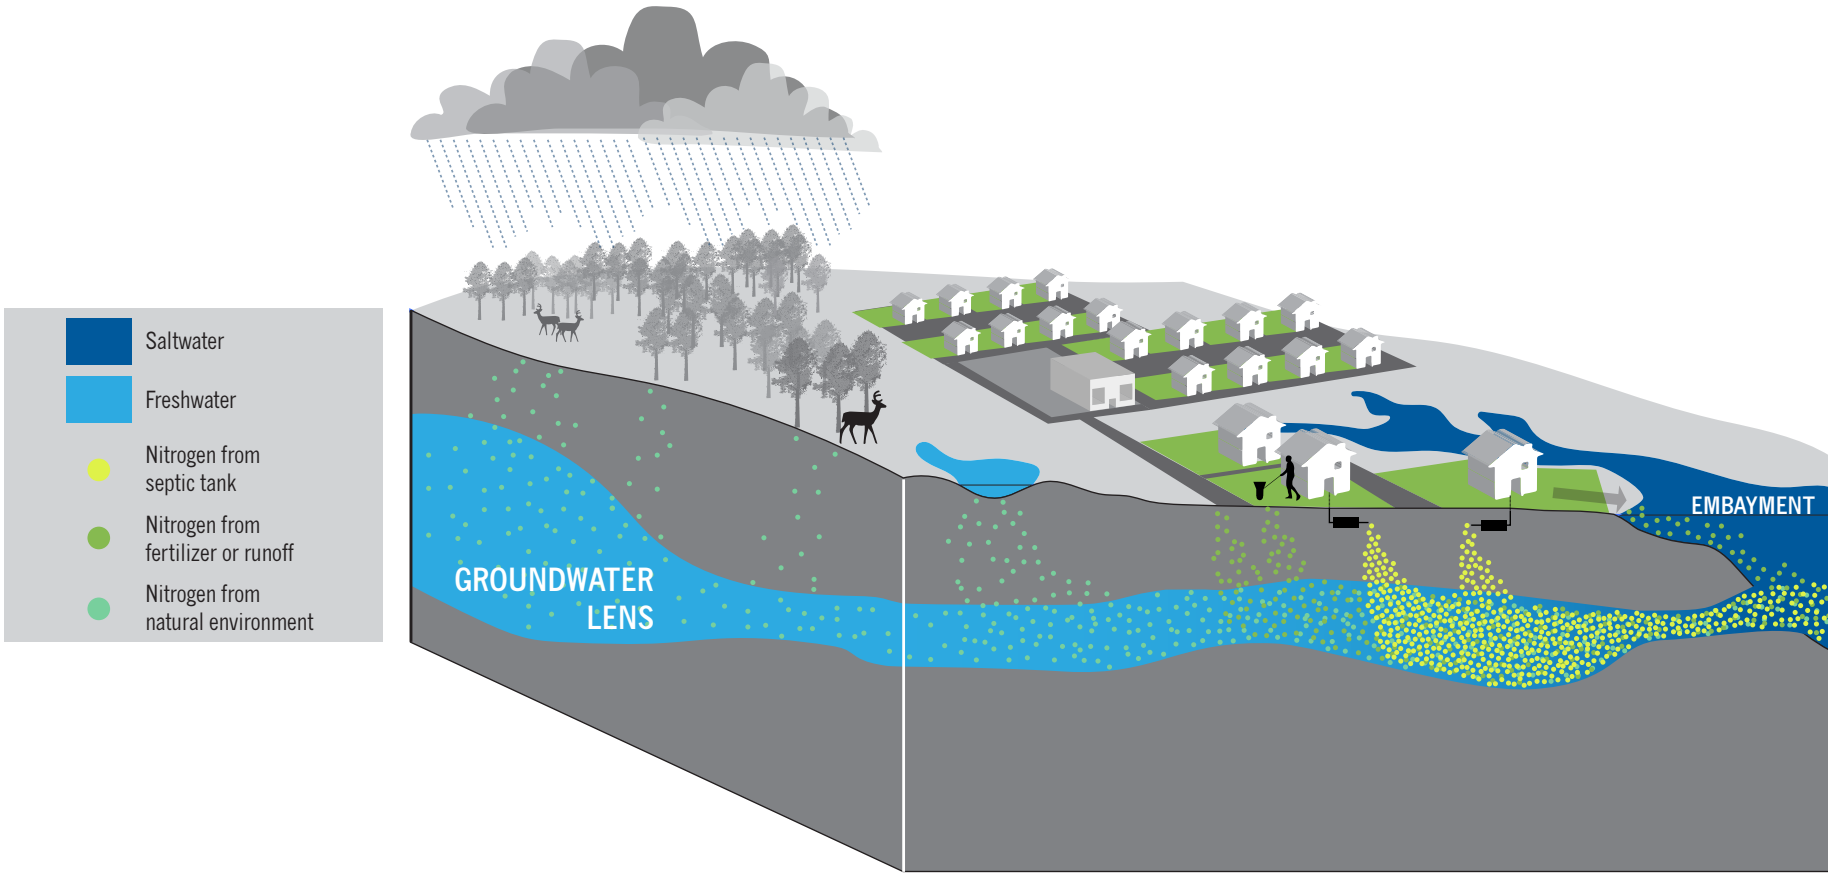
Each watershed, with its associated coastal embayment, extends from the top of the water table lens to the coastline, covering nearly 79% of the land area of Cape Cod (see **Figure 2-15** and **Figure 2-16**). The remaining 21% of Cape Cod is in a watershed where groundwater discharges directly to open coastal water such as the Cape Cod Canal, Nantucket Sound, Cape Cod Bay and the Atlantic Ocean. These are called direct discharge areas and are important areas to consider for potential wastewater discharges since the nitrogen loads do not impact the coastal embayments.

MARINE COASTAL WATER QUALITY

Watersheds are vulnerable to pollutants generated by land uses. Residential development in the last several decades sprawled across Cape Cod, consuming open space and dispersing wastewater throughout the aquifer. Nitrogen, a nutrient in wastewater, stormwater, and fertilizer, percolates into groundwater and ultimately discharges at the coast (**Figure 2-17**). The impact of nitrogen on coastal embayments is a major cause for concern on Cape Cod. Wastewater from septic systems was found to be the primary source of nitrogen overloading the coastal embayments.

In healthy embayment ecosystems, eelgrass is the dominant plant type and survives on sparse amounts of nitrogen. However, when too much nitrogen is added to an embayment, excessive algae is produced, resulting in large algal mats that shade out eelgrass and destroy animal habitat, which eventually leads to a loss of shellfish. This is referred to as the process of eutrophication. In some cases, severe conditions of anoxia have occurred that also result in fish kills and aesthetically unpleasing conditions.

TThe maximum amount of a pollutant that a water body can receive and still meet water quality goals is defined as a Total Maximum Daily Load (TMDL) under the Federal Clean Water Act. As described in guidance from the United States Environmental Protection Agency (US EPA), a TMDL identifies the loading capacity of a water body for a particular pollutant. US EPA regulations define loading capacity as the greatest amount of a pollutant that a water body can receive without exceeding water quality standards. Recent Cape Cod TMDLs have focused on nitrogen.TMDLs are established to protect and/or restore the estuarine ecosystem, including eelgrass, the leading indicator of ecological health. TMDLs are technical planning documents. Federal, state and local authorities implement



Contributing Nitrogen to Coastal Embayments

Figure 2-17

TMDLs through various legal instruments such as state groundwater discharge permits and National Pollution Discharge Elimination System (NPDES) permits.

Concurrent with the beginning of our awareness about the effect of nitrogen in coastal waters, the Commission adopted a regulatory requirement that development projects within watersheds to impaired embayments must have no-net nitrogen loading. In other words, the amount of nitrogen added by a project must be offset by an equivalent reduction. Several County-appointed committees that reviewed the Commission's regulatory program accepted this requirement as a necessary interim step to halt continued degradation of the Cape's coastal water quality. Over the years, it became increasingly clear to organizations involved in assessing and protecting embayments that a comprehensive effort to link regulatory and scientific activities was necessary to realize solutions for observed coastal water quality problems.

The general science to define critical thresholds and TMDLs advanced considerably over the past two decades. Efforts include defining watersheds, estimating watershed nitrogen loads, collecting water quality data, modeling tidal flushing and evaluating ecosystem interactions between embayment species. One project spearheading these efforts is the Massachusetts Estuaries Project.

MASSACHUSETTS ESTUARIES PROJECT

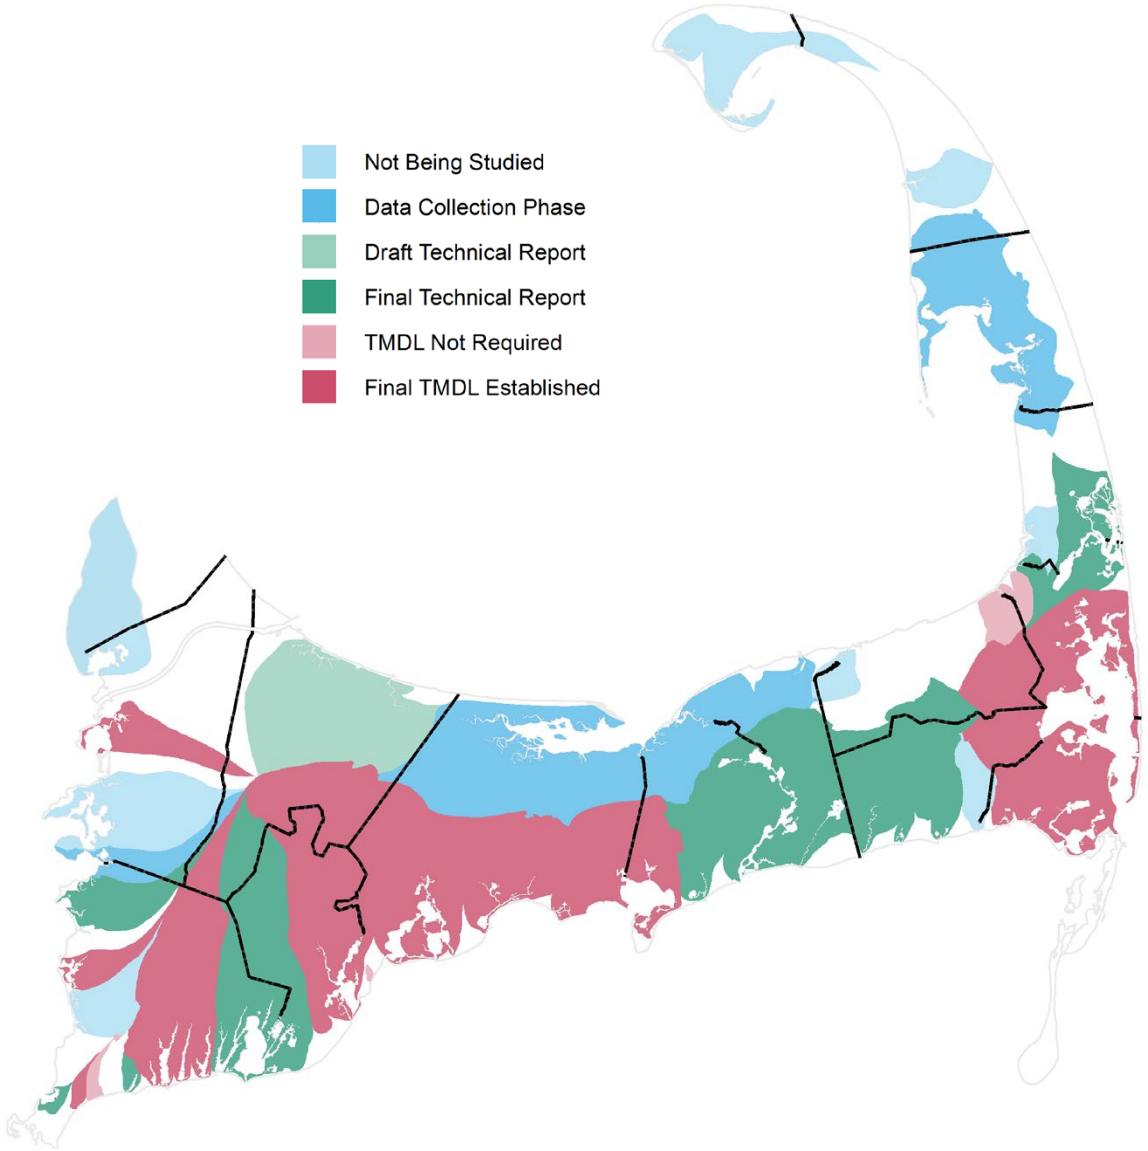
In 2001, the Massachusetts Department of Environmental Protection (MassDEP) and the University of Massachusetts-Dartmouth, School of Marine Science and Technology (SMAST) began the Massachusetts Estuaries Project (MEP). The MEP was estimated to cost $12 million over six years. Funding is broad-based with half coming from the state and the other half coming from local and other agency and non-profit sources. Barnstable County, through the Cape Cod Commission and the Cape Cod Water Protection Collaborative, provided over $700,000 to the MEP over the last eight years as direct assistance to participating Cape Cod towns. The MEP resulted in technical reports and documents that have been approved by state, federal, and county regulatory agencies. The MEP's regionally consistent methodology provides technical work and documents at significant cost savings over towns undertaking similar work individually.

The MEP developed a rigorous linked-model approach that includes components of the various disciplines necessary to understand and project how nonpoint source nitrogen loading in a watershed can result in coastal water quality deterioration. Data input into these models includes: at least three years of volunteer-collected coastal water quality data, tidal flushing data, bathymetric information for estuaries and freshwater ponds, pond water quality data, current and historic eelgrass coverages, water use information, wastewater treatment plant performance, landfill monitoring data, watershed delineations, sediment nutrient regeneration, and wetland nitrogen attenuation.

MEP Report Status and Findings

The MEP provides specific documentation that many of Cape Cod's watersheds have impaired water quality and ecological damage due to nitrogen loading. The results of many technical reports were used to develop federal- and state-approved TMDLs. As of February 2015, 35 watersheds have completed MEP technical reports, two are in draft form, and four are pending. There are 12 embayments not scheduled for study by MEP because nitrogen is not believed to be a critical issue due to tidal flushing, low intensity development, or geomorphology. US EPA approved 12 TMDLs for embayments on Cape Cod. One additional TMDL is currently pending final US EPA approval. MassDEP is drafting additional TMDLs based on MEP technical reports. The results of the technical reports have been adopted as the federal and state approved TMDLs, which makes them the basis for watershed nutrient management. **Figure 2-18** shows the status of the technical reports and TMDLs by watershed.

Although the amount of nitrogen entering the watershed is an important consideration in evaluating the potential impact on coastal embayments, other factors such as tidal range and embayment volume play significant roles. Embayments on the southern coast of Cape Cod are more susceptible to impacts because the tidal range is approximately three feet while the range observed in Cape Cod Bay is nine feet. Therefore, more water is available to dilute and remove nitrogen loads in the Cape Cod Bay embayments than the southern embayments.



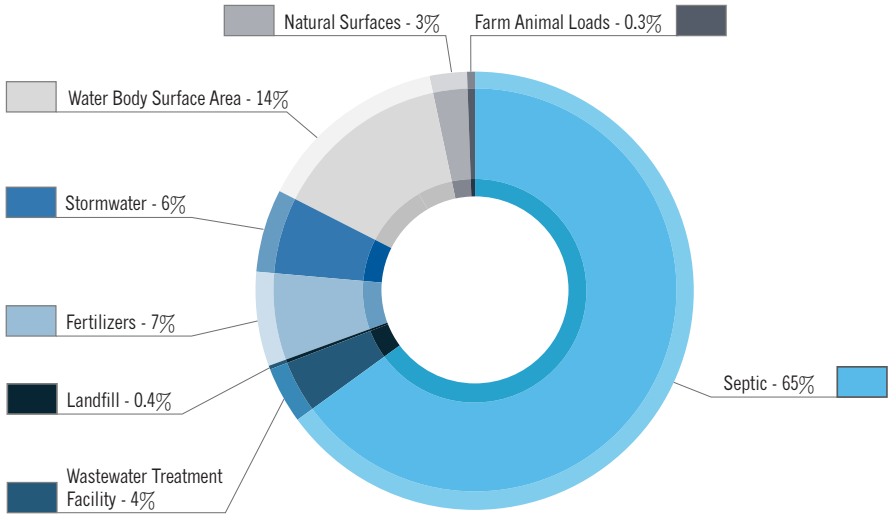
Status of MEP Technical Reports and TMDLs by Watershed

Figure 2-18

MEP Peer Review

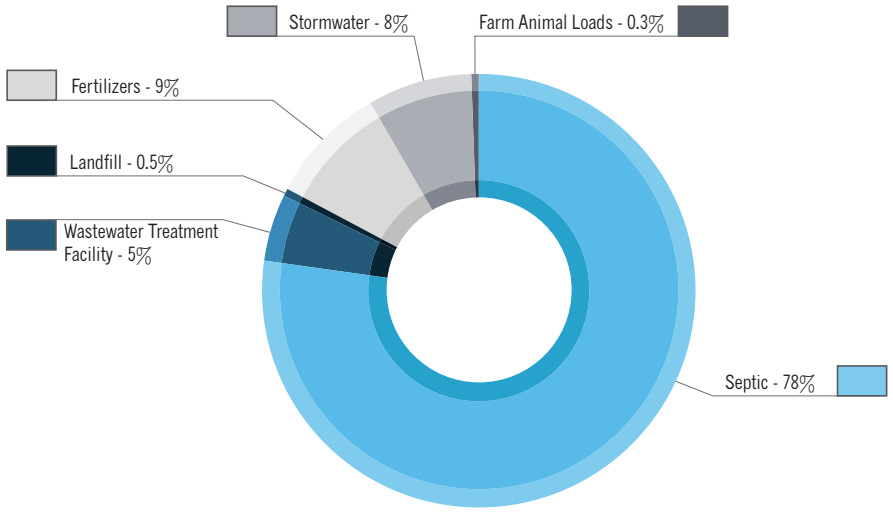
In response to concerns raised by some Cape Cod communities regarding the validity of the MEP scientific approach, the Barnstable County Commissioners directed the Cape Cod Water Protection Collaborative to undertake a scientific peer review of the MEP process. In 2011, the Collaborative organized an independent scientific peer review of the MEP methodology for developing appropriate TMDLs for the estuaries and embayments of Cape Cod, and for the use of that methodology as a basis for wastewater and nutrient management planning and implementation on Cape Cod. The scientific peer review process was independent and objective, and operated externally from the Collaborative and from any other Cape Cod stakeholders.

The peer review panel found the MEP modeling approach to be appropriate and useful for evaluating alternative scenarios and informing nutrient management plans, and also found the MEP to be consistent with existing nationwide TMDL practices. The panel also found that the MEP modeling approach is scientifically credible, and the modeling approach is consistent with current understanding of existing conditions for Cape Cod estuaries, based on available data. The components in the approach are well known and documented. Computation of watershed nitrogen loads is strongly data-driven and quantitatively linked to estuarine nitrogen concentrations. For more information see the MEP Peer Review Executive Summary or the full report of the MEP Scientific Review Panel on the Cape Cod Water Protection Collaborative website (www.ccwpc.org).



Total Nitrogen Sources by Percentage

Figure 2-19



Controllable Nitrogen Sources by Percentage

Figure 2-20

Controllable and Total Loads

The MEP provides specific documentation, based on water quality testing and ecological habitat assessments, indicating that many of Cape Cod's embayments have impaired water quality and ecological damage due to nitrogen loading. The MEP identifies the primary controllable nitrogen sources as wastewater, fertilizer and stormwater. Smaller sources include treated wastewater, landfills and farm animal waste. Septic nitrogen accounts for nearly 80% of the controllable nitrogen load in Cape Cod embayments. **Figure 2-19** and **Figure 2-20** show a Cape-wide breakdown of nitrogen sources for total load and controllable load, respectively.

Some TMDL reports approved by the US EPA include nitrogen loads to natural surfaces and water body surface areas as controllable. The MEP technical reports and TMDL reports approved by the US EPA estimate the total load of nitrogen in a watershed and specify how much needs to be removed to meet the TMDL. Since septic system contributions account for most of the controllable nitrogen load in each Cape Cod watershed, the MEP technical reports and TMDL reports also specify how much septic system nitrogen alone would need to be removed to meet the TMDL. The average reduction rate for septic nitrogen load to meet water quality standards exceeds 50% Cape-wide.

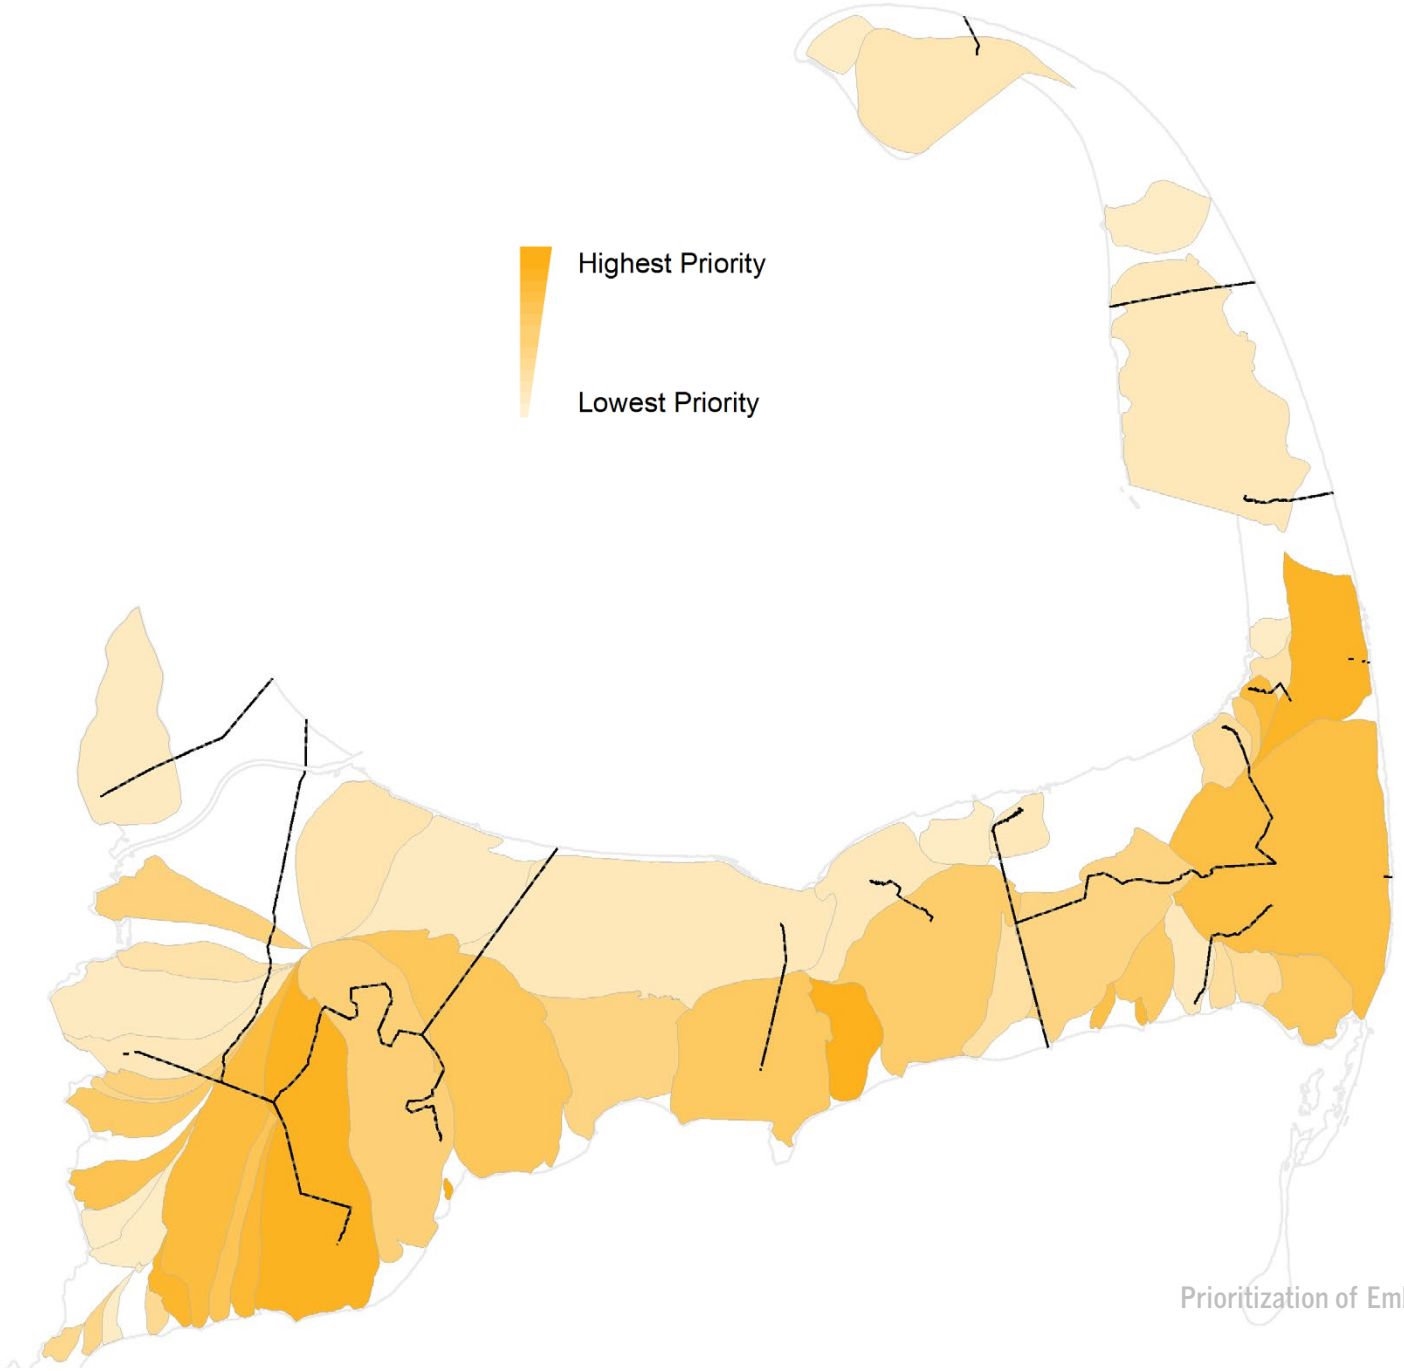
CRITERIA	SCORE	SCORE DEFINITION	DATA SOURCE
Habitat	4	Severe Degradation	Ecological health section of MEP technical reports
	3	Significant Impairment	
	2	Moderate Impairment	
	1	Healthy Habitat Conditions	
% Septic Nitrogen Removal Required after Attenuation	4	Upper quartile (>80%)	Critical nutrient threshold section of MEP technical reports
	3	Upper mid quartile (52-80%)	
	2	Lower mid quartile (35-52%)	
	1	Lower quartile (<35%)	
% Nitrogen Attenuated by Natural Processes	4	Lower quartile (<4%)	Watershed nitrogen load section of MEP technical reports
	3	Lower mid quartile (4-11%)	
	2	Upper mid quartile (11-21%)	
	1	Upper quartile (21-44%)	
Total Nitrogen Load	4	Upper quartile (25,400-85,000 kg-N/yr)	Watershed nitrogen load section of MEP technical reports
	3	Upper mid quartile (9,060-25,400 kg-N/yr)	
	2	Lower mid quartile (2,810-9,060 kg-N/yr)	
	1	Lower quartile (<2,810 kg-N/yr)	
CWMP Status	4	Preferred plan identified but not implemented	Local CWMPs
	3	Alternatives identified	
	2	Needs assessment conducted or MEP technical report completed	
	1	CWMP approved and being implemented	
	0	No CWMP or none anticipated	
Regional Opportunity	3	All municipalities in shared watershed contribute significant nitrogen load to the embayment	MEP nitrogen loads and local water use data
	2	Only one municipality in shared watershed contributes significant nitrogen load to the embayment	
	1	Watershed is wholly within one municipality	
(High ranking and score = higher priority for study)			

Watershed Priority Ranking Criteria

Table 2-1

As a means of identifying a prioritized list of watersheds for study, criteria were established to rank watersheds by subregion (Upper Cape, Mid Cape, Lower Cape, and Outer Cape). Ranking criteria included habitat, total nitrogen load, percent septic nitrogen removal required after attenuation (natural nitrogen reduction), percent nitrogen attenuated by natural processes, CWMP status, and regional opportunities. **Table 2-1** provides details on each of the ranking criteria.

Using the above criteria, watersheds are ranked and prioritized for planning (**Figure 2-21**). All of the embayment watersheds are impacted by nitrogen loading from their watersheds or are at risk for future impairment and should have access to State Revolving Fund (SRF) loans. This prioritization is strictly for planning purposes and not for prioritizing where resources should be made available. Appendix 2A provides specific ratings and scores for each watershed shown in the map. The data used to develop these scores will be updated as new information becomes available.



Prioritization of Embayment Watersheds

Figure 2-21

Ponds

Figure 2-23

FRESHWATER

Lakes and ponds on Cape Cod formed about 12,000 years ago during the Wisconsinan glaciation. As glaciers retreated from Cape Cod, large pieces of ice were left behind. When these pieces of ice melted, the area above each collapsed forming large depressions in the land called kettle holes (**Figure 2-22**). These land depressions dip below the water table, creating the hundreds of ponds seen today.

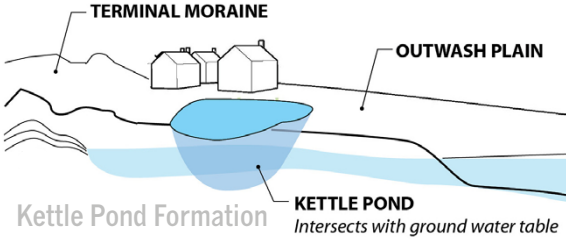


Figure 2-22

Typically, ponds lack a surface water inlet or outlet. Instead, there is a steady inflow and outflow of water between the ponds and the adjacent aquifer, which is why scientists often refer to freshwater ponds as windows into the aquifer. As part of the regional aquifer system, the ponds are directly linked to drinking water and coastal estuaries, as well as any pollutants added to the aquifer.

Cape Cod has 996 ponds covering nearly 11,000 acres (see **Figure 2-23** and **Table 2-2**). These ponds are highly variable in size, ranging from less than one acre to 735 acres, with the 21 biggest ponds making up nearly half of the total Cape-wide pond acreage. Approximately 40% are less than one acre and 166 are designated as great ponds of 10 acres or more (Cape Cod Ponds and Lakes Atlas, 2003).

Freshwater ponds are an important part of the Cape Cod ecosystem. They provide critical habitat for freshwater fish species, including: perch (yellow and white), brown bullhead, pumpkinseed, bass (largemouth and smallmouth), banded killifish, American eel and alewife. Ponds also provide resources for people. Year round and seasonal residents use ponds for recreational activities such as swimming, boating and fishing. Recent property values and sales show that demand for pond-front properties is increasing and use of existing residences is intensifying.

In 2001 the Cape Cod Commission, for a coalition of groups interested in protecting ponds, known as the Ponds and Lakes Stewardship (PALS) project, received a $30,000 grant from the Massachusetts Watershed Initiative to develop a Cape Cod pond stewardship strategy.

The Cape Cod Pond and Lake Atlas, published by the Cape Cod Commission in 2003, provides a status report on the PALS program. The Atlas documents the outreach and education activities leading to the creation of the PALS program and reviews water quality data collected by volunteers during the 2001 PALS Snapshot from over 190 ponds. This data was used to develop Cape Cod-specific indicators of pond impacts. Along with data collected in previous studies, the atlas details further efforts necessary to move pond protection and remediation forward on the Cape. The section on Pond Water Quality below includes a summary of the results and products of the PALS efforts.

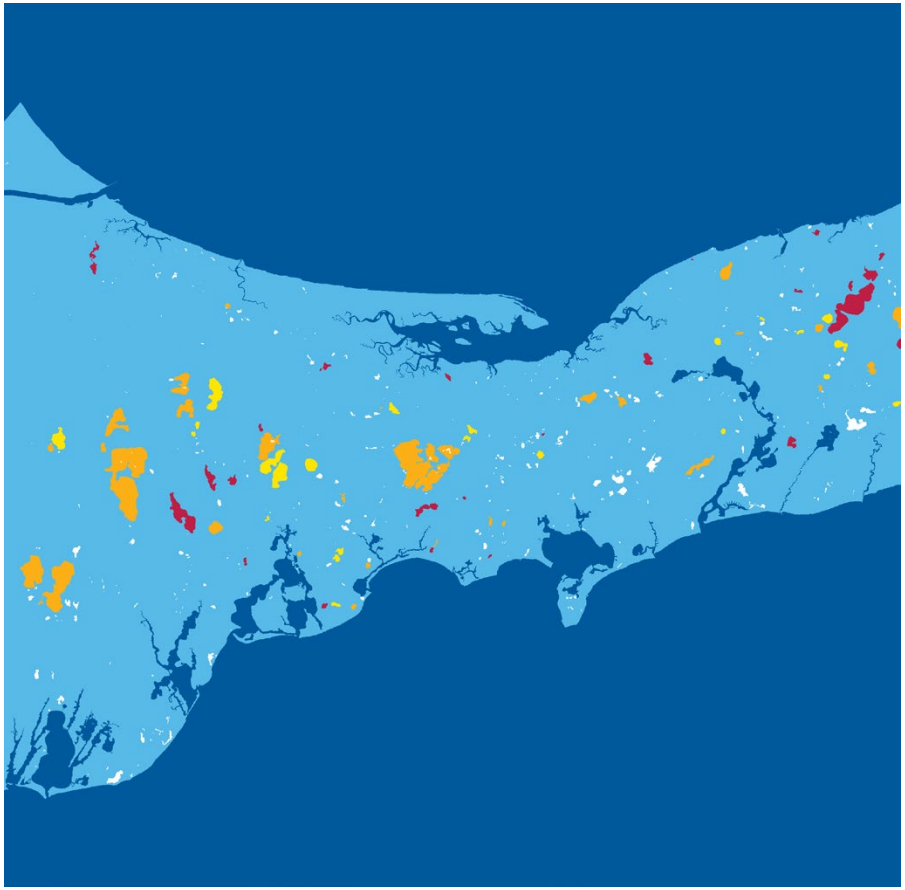
Figure 2-24



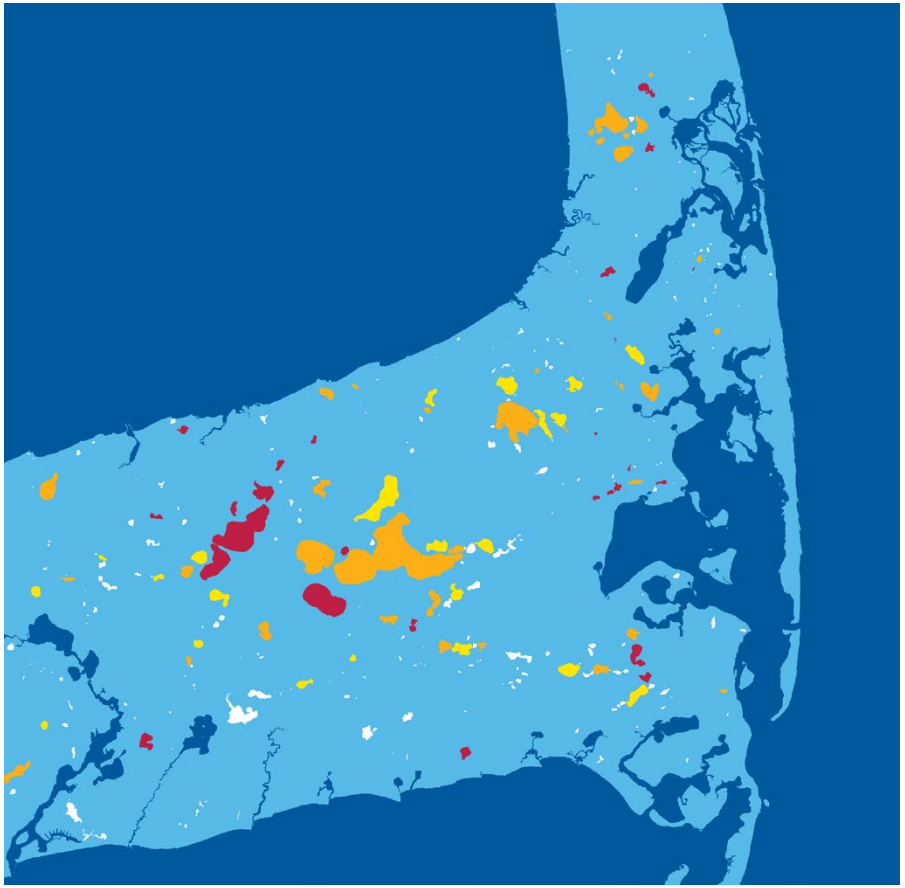
Mid Cape Pond Trophic Status

Figure 2-25

POND WATER QUALITY

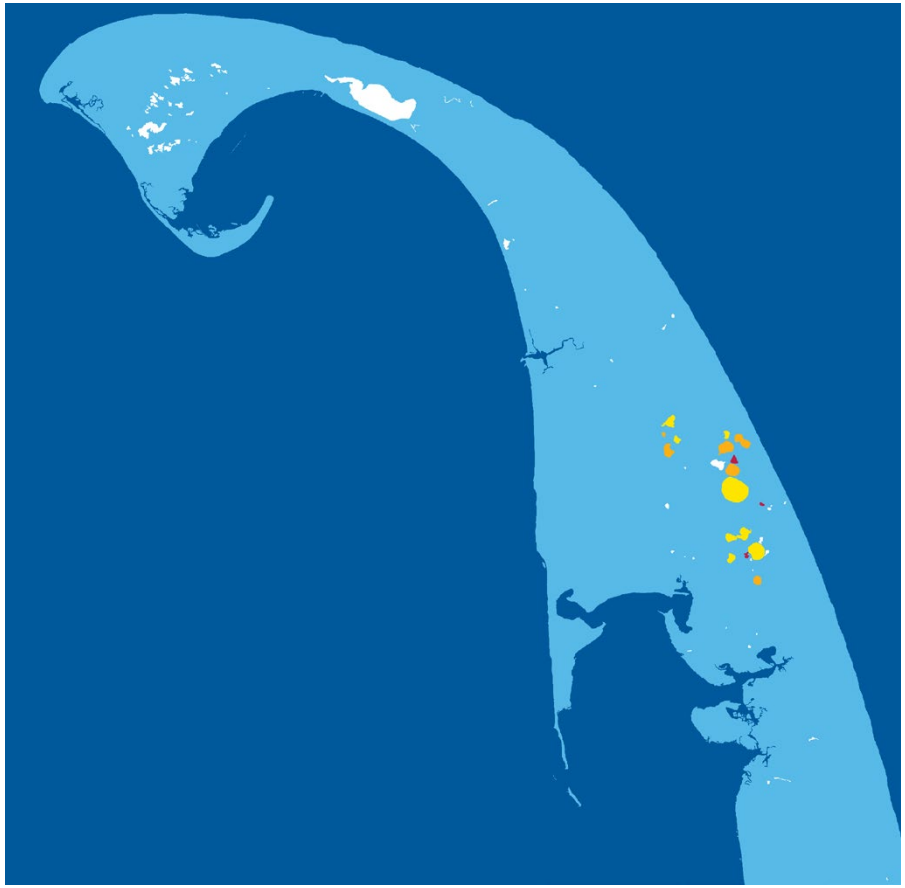
Freshwater ponds are fragile systems and their water quality is significantly impacted by surrounding land development. The soils lack the geological buffering to neutralize acid rain and allow pollutants to drain rapidly. The slow buildup of nutrients from surrounding land use and development impacts ponds through the process of eutrophication, but it can be difficult to detect and abate. The key nutrient of concern for freshwater ponds is phosphorus. Physical impacts to ponds also result from the loss of shoreline buffers as pond front property is developed, lawn area increases, and shorelines erode.

The Massachusetts Department of Environmental Protection established Surface Water Quality Standards (314 CMR 4.00), which are briefly discussed below (www.mass.gov/eea/docs/dep/water/resources/07v5/12list2.pdf). These standards are the basis for listed freshwaters under the 303(d) list for impaired waters. There are 19 fresh water ponds on Cape Cod presently listed on the



Lower Cape Pond Trophic Status

Figure 2-26



Outer Cape Pond Trophic Status

Figure 2-27

2012 Massachusetts Integrated List. Of these, 16 ponds are Category 5 Waters requiring a TMDL. Impairment causes include, but are not limited to, excess algae growth, phosphorous, turbidity, chlorophyll a, Secchi Disk transparency, abnormal fish histology, non-native aquatic plants, mercury in fish tissue, and dissolved oxygen.

A comparison of 2001 dissolved oxygen concentrations from the Cape Cod PALS project with concentrations measured in 1948 suggests that many of these pond ecosystems are not only impacted, but also seriously impaired (see **Figures 2-24** through **2-27**). Based on information in the Pond Atlas, between 74% and 93% of the Cape's ponds are impacted by surrounding development or uses.

Cape Cod Ponds Trophic Status Legend

- Eutrophic
- Mesotrophic
- Ogliotrophic
- Not Interpreted

Based largely on dissolved oxygen information, approximately 45% of all ponds and 89% of the deepest ponds are impaired. The findings suggest that the low dissolved oxygen concentrations observed in the ponds are not "natural" conditions, but are the reflection of 50 years' worth of impacts from surrounding development and land use.

Freshwater ponds play a role in coastal watershed nutrient budgets. They are credited with reducing 50% of the nitrogen load headed toward marine embayments through the process of attenuation. Freshwater ponds are surface water resources that wastewater management plans should include as part of a comprehensive analysis of local water quality. The following provides a general background on the number, condition and significant regional and local efforts to assess and manage these resources.

The annual PALS Snapshot monitoring program has continued every year since 2001 through the continued collaboration of local, county and state university programming and includes a database of over 3,500 samples for 195 ponds in all 15 towns. As part of the overall PALS program, SMAST continues to provide laboratory services at no cost to towns or volunteers for the annual PALS Snapshot of pond water quality. Many towns take advantage of the opportunities presented by the annual PALS Snapshots, and expanded their town monitoring programs. These local efforts and additional funding by the Barnstable County Growth Management Initiative enabled a number of additional lake and pond assessments to be completed in the past decade.

These reports include town wide and pond specific assessments:

Water quality degradation of Cape Cod lakes and ponds has numerous causes, but most are linked to increased nutrient loads associated with shoreline development. Management strategies identified to lessen future impacts from development include: in-pond restoration using alum or oxygen infusion devices; establishing minimum setbacks for septic systems, roads and lawns; providing natural buffer strips between lawns and ponds; treatment of direct and near shore stormwater runoff; and continued public education. The state prepared a Generic Environmental Impact Report on pond restoration alternatives that is used by towns to streamline permitting of restoration projects. The Cape Cod Regional Policy Plan requires a 300-foot buffer for Title 5 leaching systems from pond shorelines. The 300-foot buffer is used for calculating phosphorus budgets from septic systems because phosphorus is rapidly attenuated in groundwater. If a pond is significantly impacted by surrounding septic systems, a reduction of nutrients through wastewater management may be necessary. Any management plan must include continued sampling and monitoring of conditions within the pond.

Although snapshot water quality data collected over the past decade indicate significant ecological impacts, most ponds still provide the majority of uses that Cape Codders desire. Bacterial testing of ponds has generally indicated healthy conditions for swimming. Fishing and boating are still popular and recent property values and sales show that demand for pond-front properties is increasing.

Regular stocking of deep ponds sustains trout fisheries, but trout generally do not have adequate habitats to make it through a summer due to lack of oxygen in the cold waters of deeper ponds. Increased nutrients generally favor bass fishing, but half of the 18 ponds tested for mercury now have health warnings about consumption of fish tissue.

Actions to correct these ecological impairments will depend on community and state priorities. Active discussion of ecological management strategies for these ponds may lead to refinement of pond users' expectations for habitat and recreation and future TMDLs for ponds.

Despite data gathered by citizen monitoring groups and assessments that document water quality impairment, the state has listed only a few freshwater ponds on the 303d list for impaired waters for nutrients under the Clean Water Act. Additional dialogue is needed between the towns, state and county to evaluate the best use of the information collected and how it should be incorporated into the Commonwealth's clean water program.

GROUNDWATER/DRINKING WATER

The Cape Cod aquifer is one of the most productive groundwater systems in New England. It is a sole source aquifer providing drinking water to a daily summer peak of more than 500,000 people. There are 17 separate water districts or departments across Cape Cod. All together there are 158 gravel pack municipal water supply wells, one surface reservoir and hundreds of private wells. Approximately 85% of Cape Cod is serviced with public water. The remaining 15% rely on private or small volume wells in the communities of Sandwich, West Barnstable, Eastham, Wellfleet and Truro. Since 2000, public community drinking water suppliers have pumped, on average, about 10.7 billion gallons of groundwater per year from Cape Cod's sole source aquifer. Over the last decade, pumping has been fairly consistent, only showing slight variations due to seasonal climatic variations. Studies by the USGS indicate that groundwater pumping is equivalent to approximately 10% of the annual recharge from precipitation.

The Cape Cod Commission analyzed water use data from municipal water suppliers. The total amount of water use was confirmed by comparing 2008 to 2010 data from water suppliers to the total amount reported in the Annual Statistical Reports that suppliers submit to the MassDEP. The results indicate that public water suppliers provide 9.3 billion gallons of water per year to Cape Cod. Applying average water use rates for residential and non-residential uses to parcels served by private wells adds 1.2 billion gallons of water per year for a total of 10.5 billion gallons of water per year. These numbers can be converted to water use in gallons per day (gpd) per residential lot. The average residential per lot water use on Cape Cod is 169 gpd. The average non-residential water use is 586 gpd.

Information about water use is essential to planning for wastewater infrastructure. The amount of water use by parcel is fundamental data that is used to estimate wastewater generation. The MEP convention is that approximately 90% of the water used by a household ends up as wastewater.

DRINKING WATER PROTECTION

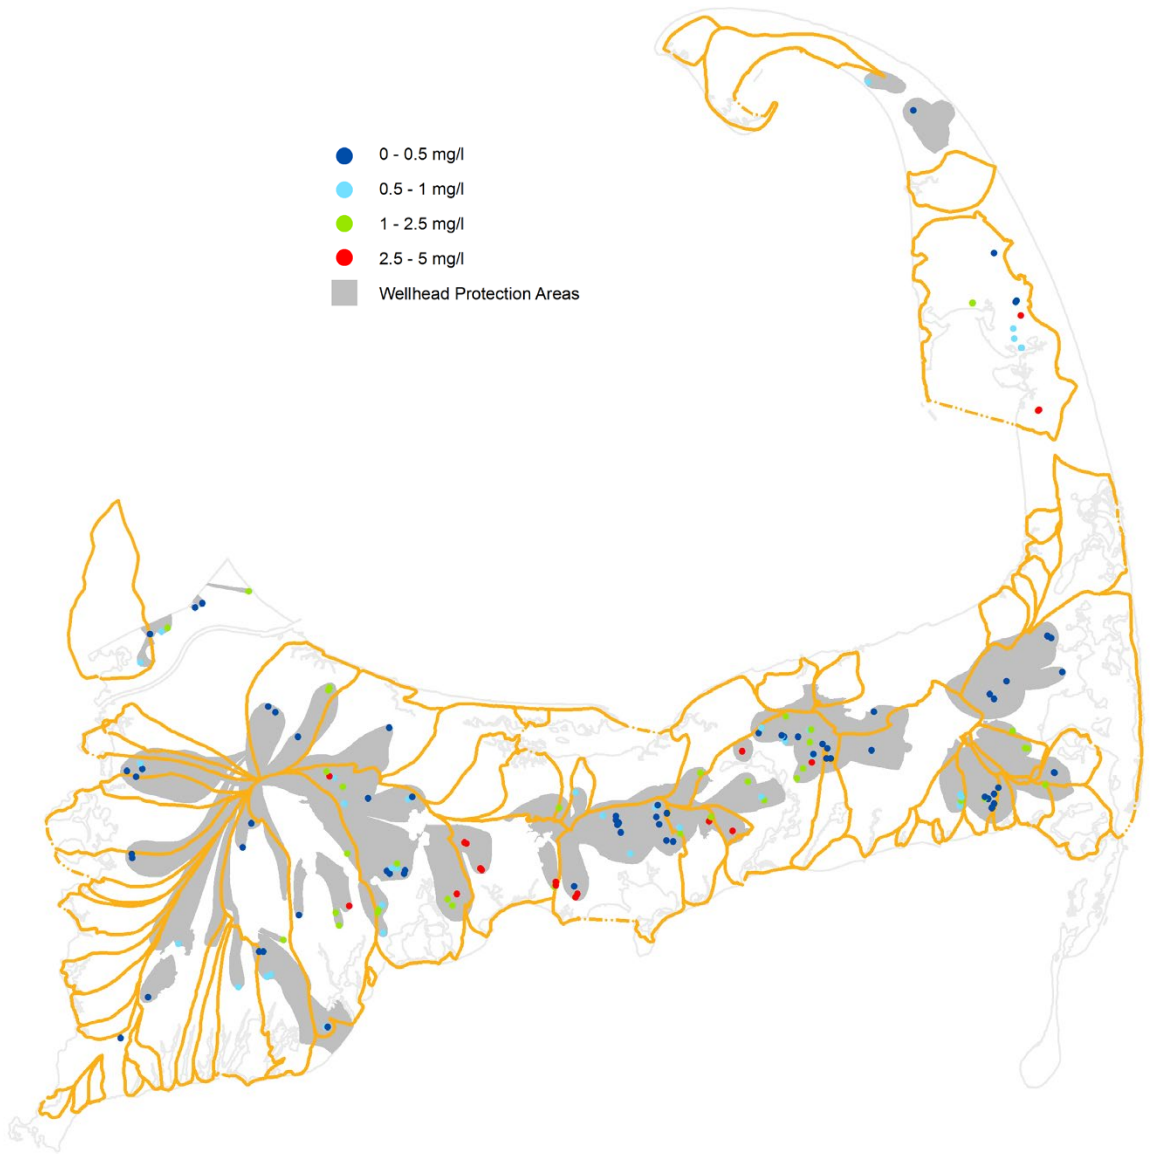
The Cape Cod Aquifer is extremely susceptible to contamination from various land uses and activities. The aquifer has been seriously impacted in the past from military activities, gas stations, landfills and a host of other activities. These examples led to strategies to protect the aquifer at all levels of government and spawned a vigorous industry for the assessment and clean-up of contaminated groundwater. The drinking water of Cape Cod is generally well protected as a result of these activities.

Over the last several decades water planners combined their knowledge of groundwater with policy mechanisms to protect Cape Cod drinking water. Adoption of wellhead protection areas (or Zone IIs) was a major strategy to protect the land area that receives precipitation to recharge the pumping wells. Today each town has zoning and Board of Health bylaws to protect their wellhead protection areas, which are collectively shown in **Figure 2-28**.

In addition, the public embraced acquisition of land for protection of wellhead areas through local, regional and state actions like the Cape Cod Land Bank (later the Community Preservation Act). The Wellhead Protection Area state regulations (310 CMR 22) and Cape Cod Regional Policy Plan (RPP) minimum performance standards prohibit or limit land uses that are potentially detrimental to drinking water quality.

GROUND WATER QUALITY ISSUES

Nitrate, a major component of human wastewater, passes through septic systems virtually untreated and is introduced to the underlying groundwater. Nitrate concentration is often used as an indicator of drinking water quality. A maximum contaminant limit (MCL) of 10 parts per million (ppm) of nitrate for drinking water supplies has been established by the US EPA and adopted by Massachusetts state



Wellhead Protection Areas

Figure 2-28

regulation. The limit was established to protect infants from methemoglobinemia, or "blue-baby" syndrome, a potentially fatal blood disorder that can occur when too much nitrate limits the amount of oxygen in the blood. The RPP established a nitrogen loading concentration of 5 ppm to ensure that nitrate levels in drinking water will not approach the 10 ppm federal standard.

Massachusetts Drinking Water Regulations (310 CMR 22.00) define two types of public drinking water supplies - community and non-community. Community public supply wells include large municipal wells pumping over 100,000 gpd, but also include small volume wells that serve at least 25 year-round residents or at least 15 service connections used by year-round residents. The small volume wells include service to schools, town halls, and community centers mostly located in the Outer Cape that lack large municipal wells. Anything not covered by the definition of community is served by non-community or private wells. Non-community public supply wells fall in to two categories - non-transient and transient. A non-transient non-community public supply well regularly serves at least 25 of the same persons or more for approximately four or more days per week, more than six months or 180 days per year, such as a school. Transient non-community public supply wells serve 25 different persons at least 60 days of the year. Some examples of these types of systems are restaurants, golf courses and community centers. The quality of Cape Cod's community public drinking water supply is generally very good. The percentage of community public supply wells that had nitrate levels at or below 0.5 ppm, which is considered very good, fell from 57% to 42% between 1993

and 2008. Even well protected community public water supply wells have elevated concentrations of nitrate derived from septic systems and other nonpoint sources.

Small volume non-community drinking water wells which are concentrated on the Outer Cape are generally shallower, pump less water and are often closer to septic systems. These non-community public supply wells have shown a greater degradation than the larger and deeper community wells. Since 2000, the number of non-community public supply wells with nitrate concentrations below 0.5 ppm has remained around 35%.

All of the wells exceeding the drinking water limit are located on the Outer Cape where wastewater disposal and private water supply often occur on the same lot. Assessments of private wells in Truro, Wellfleet and Eastham indicate a correlation of high nitrate concentration in relation to housing densities of less than ½ acre (Water Resources of the Outer Cape, 1998). In response to poor water quality, Wellfleet invested in a public water supply system to serve its Central downtown district and Eastham has completed water supply site investigations in two locations as a first step toward a public water system. Eastham voted overwhelming in the spring of 2014 to establish a new Town water system for critical areas of the Town. In February 2015, the Cape Cod Commission approved the town's application to permit the water supply project as a development of regional impact (DRI).

Other Considerations

EMERGING COMPOUNDS: PHARMACEUTICALS AND PERSONAL CARE PRODUCTS

Nitrate can serve as an indicator of other wastewater contaminants, such as disease-causing organisms, solvents, cleaners, petroleum compounds, pharmaceuticals and personal care products (PPCPs) and other emerging contaminants. Emerging contaminants are chemicals or microorganisms that are not commonly monitored or regulated in the environment, but are suspected of having potentially adverse ecological and/or human health effects. They can include hormones, human and veterinary pharmaceuticals, and household products like soaps and lotions, insect repellents, perfumes and other fragrances, sunscreens, and hand sanitizers.

There have been numerous national studies done to investigate and document the occurrence of these emerging compounds in wastewater, surface and groundwater. In 1999 and 2000, the USGS conducted a national stream reconnaissance testing 139 streams in 30 states for 95 organic wastewater compounds (OWCs) (Kolphin et al. 2002). Eighty-two of the 95 compounds were detected in at least one sample and 80% of the streams had at least one OWC detected. In 2000, the USGS sampled 47 groundwater sites across 18 states; 98% of the sites sampled had detections of emerging contaminants, with 46 of the 83 contaminants being found at least once (Barnes et al. 2008).

During 2001, the USGS analyzed 25 ground and 49 surface-water untreated public drinking water supply sources in 25 states. The majority of the samples (96%) showed at least one emerging contaminant. The emerging contaminants were more frequently detected in surface-water than ground-water sources (Focazio et al. 2008). Generally, all of these studies have detected the presence of a variety of organic wastewater contaminants and PPCP's. The detections were more common in the stream samples (86%) and surface water samples than in groundwater (35%). Mixtures of chemicals were common and the concentrations measured were generally at low levels (often less than 1 microgram/liter), just slightly above detection levels.

In June 2004 the USGS and the Barnstable County Department of Health and the Environment sampled wastewater sources and public, semipublic, and private drinking water supplies on Cape Cod that were thought to be affected by wastewater because of previously high nitrate concentrations. Forty-three of the 85 PPCP and organic wastewater contaminant compounds tested for were detected. Thirteen were detected in low concentrations (less than one microgram/liter) in the private and semipublic drinking water supplies and three - an antibiotic, an antidepressant and a solvent - were detected in the public water supply (Zimmerman 2005).

In May 2010 the Silent Spring Institute reported that PPCPs were detected in 75% of 22 public water supply wells sampled on Cape Cod. In general, wells with higher levels of nitrate and higher density land development in

the wellhead protection areas had a greater number of detections than those wells that were better protected by lower density and open space. In a similar study Silent Spring also found detectable traces of PPCP in fresh water ponds and private wells associated with residential development. A recent assessment by the Provincetown Center for Coastal Studies detected traces of PPCP in Nantucket Sound.

Although the ability to detect these emerging compounds at extremely low levels in drinking water has been greatly improved, the human health effects from these low level concentrations are not well documented.

In the absence of better information about the actual occurrence of these compounds and the need to provide a level of protection, MassDEP recently incorporated very stringent performance standards for proposed wastewater discharges in Zone IIs. MassDEP adopted a maximum Total Organic Carbon (TOC) Concentration of 3 ppm. TOC is a surrogate for PPCP in treated wastewater. Some studies documented that PPCP will be adsorbed on to particulates of carbon. It is thought that removing this carbon will provide a level of protection to the underlying aquifer and public supply wells. However, removing TOC to this level requires an extremely high level of treatment, with 20-30% higher capital treatment costs and higher annual operation and maintenance. Investigations into the transport of PPCP have found that the majority of these compounds do not travel very far in the groundwater. In fact, monitoring wells down gradient of existing wastewater disposal sites on Cape Cod have found concentrations of TOC below the 3 ppm concentration.

The US EPA has undertaken national testing of CECs in public water supplies, referred to as the Unregulated Contaminant Monitoring Rule (UCMR). Monitoring for selected CECs is required for water supplies serving over 10,000 connections or by voluntary action. A number of Cape Cod water suppliers have volunteered to have their supplies tested. As data becomes available through the UCMR the US EPA will be able to target more prevalent contaminants for review, research and action.

Although the Section 208 Plan Update is largely focused on the ecological impacts of nitrogen, particular attention will be focused on drinking water areas and wells that have higher levels of nitrogen as an indicator to address emerging contaminants. Additional investigation on the occurrence of emerging contaminants in groundwater will be needed to address the wastewater disposal options for any particular selected site that is located in a Zone II. In relation to the MassDEP TOC requirement to address PPCPs, substantial costs can be saved by avoiding wellhead protection areas and Zone IIs when locating potential wastewater disposal sites.

County Activities

BARNSTABLE COUNTY DEPARTMENT OF HEALTH AND THE ENVIRONMENT

MASSACHUSETTS ALTERNATIVE SEPTIC SYSTEM TEST CENTER

The Massachusetts Alternative Septic System Test Center has been operating since 2000 to research and test advanced on-site wastewater treatment systems. The Center is operated by the Barnstable County Department of Health and the Environment (BCDHE) and is located at Joint Base Cape Cod. Although the Center's initial emphasis was on nutrient-reducing technologies, it has more recently been conducting research on the efficacy of commercial and soils-based septic systems for removal of pharmaceuticals and personal care products. The Center has been instrumental in forming and conducting many internationally recognized standards for both secondary and tertiary wastewater treatment. Ancillary projects include the support of research efforts on wastewater diversion techniques, such as composting toilets and urine diversion, and their efficacy for addressing the nutrient management issues in sensitive watersheds.

The majority of the systems tested at the Center are proprietary systems and the efficacies of non-proprietary denitrification strategies are less understood, primarily due to the lack of financial incentives to develop and promote them. It is clear, however, that Cape Cod communities are interested in exploring all of the options available for

reducing nitrogen that enters the groundwater. Through this process to update the Section 208 Plan for Cape Cod, funding was provided to the County Department of Health and the Environment to investigate non-proprietary means to remove nitrogen by enhancing and/or manipulating soils-based systems. This work is essential in order to assure wastewater planners, managers and the public that all options are properly evaluated. More information on the study and progress to date is available in Appendix 2B.

INNOVATIVE/ALTERNATIVE SEPTIC SYSTEMS PERFORMANCE TRACKING

More than 1,500 innovative/alternative (I/A) septic systems have been installed on Cape Cod in an attempt to reduce the amount of nitrogen discharged into the groundwater. These systems range in their complexity, but all require regular maintenance and monitoring. Since 1999, BCDHE has maintained a database to assist regulators in the task of tracking performance and adherence to maintenance schedules. Regular performance and compliance updates are provided to local regulatory boards. More recently, to aid the public and engineering professionals, the department has created an interactive tool to chart performance of all technologies used within Barnstable County. This tool assists wastewater planners to develop realistic performance expectations, thus facilitating accurate local wastewater planning. Occasionally, printed compendia of the information are distributed to local boards and commissions. The department also maintains training tools to instruct boards of health regarding the proper application of these technologies.

COMMUNITY SEPTIC MANAGEMENT LOAN PROGRAM

The Barnstable County Department of Health and the Environment initiated the Community Septic Management Loan Program to assist homeowners by defraying the costs of septic system upgrades through provision of 20-year betterments. More recently the program has assisted in providing support for the actual connection costs to centralized systems or combined packaged or cluster treatment systems. For more information visit the Community Septic Management Loan Program website at http://www.barnstablecountysepticloan.org/.

CAPE COD COMMISSION

TECHNICAL SERVICES

As the region's planning agency, the Cape Cod Commission supports its regulatory and planning mission with the provision of technical services by professional staff in almost every issue area of the Regional Policy Plan (RPP) for various county, local, state and federal agencies, associations and citizens. In the area of water resources, the Commission staff provides support on water supply, freshwater ponds, coastal water quality, wastewater management and groundwater cleanup. Staff members develop both quantitative and qualitative methods that result in finding cost-effective solutions for common problems shared across the region. Staff members have provided fundamental expertise in the development of local and regional wastewater management planning and in the development of the tools and resources developed as part of the Section 208 Plan Update.

Town Wastewater Planning Efforts

All 15 Cape Cod towns have engaged to some degree in the process of developing Comprehensive Wastewater Management Plans (CWMPs) over the last 10 years. Several towns are in the Massachusetts Environmental Policy Act (MEPA) review process. A Cape Cod Commission regulatory review file of comments letters, public hearings and decision documents are available for each town that is undergoing the MEPA/DRI review process for their CWMP. Barnstable, Chatham, Falmouth and Provincetown have existing wastewater infrastructure and have completed wastewater facilities plans prior to or in conjunction with nutrient planning. The following is a synopsis of the CWMP planning efforts in each town.

STATUS OF CWMPS

BARNSTABLE

The town of Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The town completed the MEPA/DRI review process for what is known as the Wastewater Facility Plan (WWFP) in 2007. This included upgrades and expansion of the Hyannis Water Pollution Control Facility (WPCF). The WWFP resolved

wastewater disposal issues relative to wastewater disposal site capacity and identified nine Areas of Concern (AOCs) for sewer hook-up. The DRI approval conditions require an adaptive management plan for monitoring the wastewater facility as it approaches a discharge rate of 3.7 million gallons per day (MGD), prior to attaining its design capacity of 4.2 MGD. The additional 0.5 MGD may require the use of an approved remote disposal site known as the Route 132 site. The DRI conditions also include the scope for the nutrient management plan and provisions for continuing sewer expansion under the WWFP.

The town implemented the upgrades to its present facility and completed a sewer extension project for the Stewart's Creek area in the village of Hyannis.

The town reformulated a Citizen's Advisory Committee (CAC) for wastewater planning and has been working on the nutrient management plan/CWMP. The Alternatives Screening Analysis of the CWMP was submitted as a Draft Environmental Impact Report (DEIR)/Environmental Notification Form (ENF) for joint MEPA/DRI review in May 2012. The Needs Assessment and Alternatives Screening Analysis conclude with five alternative plans, not including the no-action alternative. Each alternative assumes a portion of the town will remain on Title 5 systems, where nutrient removal is not critical, and that remote recharge sites for treated effluent will be needed. The alternatives include a totally decentralized solution; a decentralized solution with some larger facilities; and centralized alternatives with either a single town plant or multiple town plants. Since the Hyannis WPCF is located in a zone of contribution to public water supply (Zone II) and would require expensive total organic carbon (TOC) removal options, the CWMP also includes ocean outfall as an alternative, as well as the alternative of abandoning existing public water supply wells.

The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes extensive comments and significant additional work. One component of the MEPA certificate is to engage in a targeted watershed approach. The Commission is presently working with Barnstable and Yarmouth to develop a targeted-watershed scope for the Lewis Bay watershed. The Commission and the town have discussed the use of the WatershedMVP to evaluate targeted watershed approaches for Three Bays. The CAC is presently considering the next appropriate steps.

A more detailed chronology of water quality planning efforts in Barnstable is available in Appendix 2C.

BOURNE

The town of Bourne recently completed a targeted wastewater planning effort for the Buzzards Bay downtown area. A portion of the Buzzards Bay area is sewered and up to 200,000 gpd of wastewater is conveyed to Wareham for treatment and disposal. Bourne is limited to this flow through its agreement with the town of Wareham.

The Cape Cod Commission worked with the town of Bourne to develop a wastewater and water supply report for Buzzards Bay. The report provided the town with a detailed assessment of the needs, alternatives, facility siting options, and estimated costs of providing wastewater infrastructure to support the revitalization of the Buzzards Bay area. A copy of the report is available on the Commission's Initiatives webpage. The town voted to approve the report's recommendations to obtain in-house expertise to guide the project and to conduct necessary steps for siting and infrastructure evaluations. In March 2013 the town hired a wastewater coordinator and soon after hired a contractor to determine if either of two identified sites - Queen Sewell Park and land behind the Bourne Veterans Memorial Community Center - is suitable for wastewater disposal. The Queen Sewell Park site was determined to be a suitable site to consider moving forward.

The town of Bourne received a MEP technical report for Phinneys Harbor/Eel Pond and Back River, but reports for other watersheds within its boundaries, including Megansett, Sequeteague, Pocasset, and Buttermilk Bay are not complete or not planned, making it difficult to pursue meaningful wastewater assessments in these areas.

A more detailed chronology of water quality planning efforts in Bourne is available in Appendix 2D.

BREWSTER

In 2009, the Town of Brewster formed a Comprehensive Water Planning Committee (CWPC). The CWPC is charged with coordinating the efforts of the Town staff and consultants and it began the CWMP process in 2009. The town chose to pursue an Integrated Water Resources

Management Plan (IRWMP) because it wanted to closely evaluate drinking water and freshwater pond issues in addition to coastal water quality impairments.

Phase I of the IRWMP was completed in 2011. As a result the town initiated a number of intermediate projects to expand the Town's data and understanding of water quality. In January 2013, Phase II of the IRWMP was issued. The report recommends a number of alternatives for coastal nitrogen reduction in the Pleasant Bay watershed, including innovative/alternative (I/A) and cluster systems, fertilizer reduction, irrigation wells to recycle and reduce groundwater concentrations, permeable reactive-barrier technologies, and alternative toilets (see Chapter 4 for technology descriptions).

The town is continuing its efforts toward drinking water protection through its bylaws and the Brewster Water Protection District of Critical Planning Concern. A number of specific opportunities for stormwater treatment have been identified and conceptual designs have been developed. There are a number of freshwater pond protection strategies that are also recommended.

The town secured funding for Phase III of the IRWMP and began work in June 2013. The goals of Phase III are to:

- Evaluate the Pleasant Bay nitrogen management alternatives identified in the Phase II report and select a preferred plan with recommendations for what Brewster needs to do to restore water quality within Pleasant Bay;
- Finalize recommended stormwater regulations developed in Phase II;
- Encourage proper management of stormwater, septic systems, fertilizers and other potential pollutants that impact Brewster's Ponds (e.g., new regulations);
- Continue with current outreach activities (e.g., website, brochure);
- Facilitate communication between the CWPC, the Cape Cod Commission, the public, and with other town boards and agencies involved in the project.

A more detailed chronology of water quality planning efforts in Brewster is available in Appendix 2E.

CHATHAM

The Chatham CWMP of 2009 is the first town-wide plan on Cape Cod to be completed that incorporates the state and federal total maximum daily loads (TMDLs) to restore coastal water quality for several large coastal embayments. The CWMP/FEIR provides a strategy for wastewater management and reduction of nitrogen loading to restore and protect Chatham's marine embayments, addresses other areas of concern, such as areas experiencing high groundwater, failing systems, and industrial/commercial areas, and includes an adaptive management plan for its implementation.

The prior WPCF in town was built in 1970 and the collection system extended to the Main Street downtown area. Prior to development and implementation of the CWMP this facility served approximately 480 properties.

The CWMP/FEIR details a two-phased implementation program to meet nitrogen TMDLs in Stage Harbor, Pleasant Bay, Sulphur Springs, and Taylors Pond. Phase 1 average annual wastewater flows are projected to be 0.94 MGD. The Phase 2 wastewater flows will be 38 percent more than Phase 1, for an average annual flow of 1.3 MGD over 30 years. The extension of sewers to the remaining part of town will take another 10 years, with an estimated completion date of 2040.

The estimated Phase 1 costs are $210 million (in 2007 dollars) over the initial 20 years. The town has adopted a number of innovative approaches for funding the project and has established a capital facilities plan with the goal of maintaining the tax rate. However, it is acknowledged that modest tax increases will be necessary to meet the costs of the proposed plan. Homeowner charges are estimated at $3,000 to $10,000 for hook-up and $400 for annual operation and maintenance.

The state and the Cape Cod Commission reviewed this 11-year project as a DEIR in 2008 and as a FEIR in 2009. An expanded adaptive management plan scope was part of the conditions of the DRI approval, which included components of implementation progress, Groundwater Discharge Permit monitoring, and monitoring of marine waters for TMDL compliance. The final adaptive management plan was submitted to the Commission two years after the DRI approval.

The town completed the treatment facility upgrade in 2010 and the main sewer trunk line construction in 2012 and is seeking State Revolving Fund (SRF) funding for the next

stage of sewer expansion in to the Stage Harbor watershed system - an area impaired by nitrogen. In 2013 the town signed an agreement with the town of Harwich to further evaluate using a portion of the treatment capacity in Chatham to serve the eastern portion of Harwich, which is part of the shared Pleasant Bay watershed. The potential sharing of the facility is allowed by condition in the DRI approval. Chatham has also been a lead town in the effort to improve circulation in Muddy Creek with a culvert-widening project that would likely reduce nitrogen removal requirements.

A more detailed chronology of water quality planning efforts in Chatham is available in Appendix 2F.

DENNIS

The town of Dennis received MEP technical reports for Herring River, Swan Pond and Bass River. Working through the Dennis Water District, the town completed fundamental portions of a needs assessment that identified a number of areas to be addressed for both nutrients and Title 5 constraints on economic redevelopment in the area of Dennisport. The district filed and passed legislation to become the Dennis Water and Sewer District. The November 2013 special Town Meeting voted to approve funding for a consultant to study previously collected data, identify problems, and recommend possible solutions, along with their costs. The output will be a water quality evaluation and mitigation alternative study for the district and the town to consider as they plan their next appropriate steps for wastewater planning.

A more detailed chronology of water quality planning efforts in Dennis is available in Appendix 2G.

EASTHAM

The town of Eastham completed a town-wide needs assessment in March 2009. The needs assessment concluded that a new public water supply system to protect public health was an overriding concern. In 2013, Town Meeting did not approve the expenditure of funds for either a town-wide water system, at a cost of about $114 million, or a phase 1 water system, at a cost of about $41 million, to serve those areas with the greatest need.

The spring 2014 Town Meeting approved $45.8 million to fund a scaled back version of the full town-wide water system. The system is described as a "backbone with landfill study area service," which will include all the basic elements to allow for expansion to all parts of the town in the future. This backbone will include a single water tower, two wells, with service connecting along major roadways and to the affected areas within the landfill study area. It includes hydrants that will be within 1000 feet of 80% of Eastham structures. The Cape Cod Commission approved this project as a DRI in February 2015.

In addition to pursuing solutions for water supply protection, the town of Eastham is actively pursuing the protection and restoration of its freshwater ponds. The town completed a town-wide assessment and is pursuing in-pond restoration efforts. Alum treatments for Herring Pond and Great Pond are complete and others are under consideration.

Eastham shares the watershed to the Nauset estuary with the town of Orleans and is willing to have further discussions about potential opportunities to share the wastewater treatment facility proposed in the approved Orleans CWMP.

A more detailed chronology of water quality planning efforts in Eastham is available in Appendix 2H.

FALMOUTH

The town of Falmouth completed the MEPA/DRI process for the West Falmouth Harbor WWFP in 2001. The WWFP focused on a necessary upgrade to the existing treatment facility in order to achieve better nutrient-removal rates. The sensitivity of West Falmouth Harbor to nitrogen loading was not well understood when the facility was permitted in the 1980s. The upgrade is now complete and water quality conditions within the groundwater have improved significantly. However, the disposal location has a limited capacity due to sensitivity of the estuary to additional nitrogen inputs.

The Cape Cod Commission reviewed an ENF for the Town of Falmouth Comprehensive Wastewater Management Planning Project for the South Coastal Watersheds in 2007. The ENF included the Needs Assessment Report and Alternatives Screening Report for Little Pond, Great Pond, Green Pond, Bournes Pond, Eel Pond, and Waquoit Bay. This draft CWMP included collection of wastewater in the south coastal areas, generally south of Route 28, treatment at a proposed regionally-shared facility at Joint Base Cape Cod (MMR at the time), and effluent disposal through

injection wells. The town formulated a new internal review committee, the Water Quality Management Committee (WQMC), to evaluate additional alternatives, and in 2012 submitted a draft CWMP/DEIR for joint MEPA/DRI review.

The 2012 draft CWMP/DEIR represented a significant change from the screened alternatives presented in the 2007 ENF. In addition to plans for sewering specific portions of the south coastal estuaries and upgrading the West Falmouth treatment facility and discharge options, the DEIR included specific opportunities for innovative on-site technologies and non-discharging systems, tidal flushing, aquaculture, permeable reactive barrier demonstration projects, and non-structural nitrogen reduction strategies consisting of fertilizer controls and stormwater management.

Through its review, the Commission supported the additional evaluation of Joint Base Cape Cod as a potential shared regional facility for the Upper Cape as one the town's alternatives.

The town received wastewater grant funds from Barnstable County for:

- technical assistance from the USGS and Cape Cod Commission staff to use a groundwater model to evaluate potential wastewater disposal sites;
- detailed hydrogeologic modeling of a likely discharge site, the Falmouth Country Club; and,
- technical assistance through the Cape Cod Water Protection Collaborative.

The town implemented the recommendations of the WQMC and Town Meeting approved $2.77 million to retain an omnibus engineering consultant to oversee design aspects of the entire project and separate expert consulting capacity to prepare feasibility studies for the pilot projects. Spring 2013 Town Meeting appropriated $9 million to provide the design of the Little Pond watershed collection system, necessary facility upgrades, and pilot project implementation.

In January 2014, a MEPA Certificate of Adequacy was issued for the Falmouth South Coast Watersheds CWMP. The certificate details how projects included in the CWMP will come forward as Notices of Project Change in the future. The Commission approved the CWMP as a DRI in February 2014 with conditions to develop an adaptive management plan.

Spring 2014 Town Meeting subsequently approved $50 million to construct a targeted watershed approach for a Little Pond watershed collection system and implement the pilot projects over the next five years, concluding in 2020.

A more detailed chronology of water quality planning efforts in Falmouth is available in Appendix 2I.

HARWICH

The town of Harwich established a water quality management task force to coordinate both fresh and marine water sampling. The task force is responsible for wastewater planning, which consists of developing a CWMP and participating in the Pleasant Bay Alliance.

The Harwich efforts were on hiatus while waiting for the Massachusetts Estuaries Project (MEP) to complete the technical reports for Herring River and several of the south-side embayments. These reports were received by the town in 2010-2012.

The town has since submitted an expanded ENF and anticipates participating in joint MEPA/DRI review with the Cape Cod Commission.

The CWMP includes options for regional infrastructure with the town of Chatham for the East Harwich economic development area of town (part of the shared Pleasant Bay watershed). The town recently signed an agreement with the town of Chatham to evaluate this option.

Harwich is also the lead town in a shared effort to improve circulation in Muddy Creek with a culvert-widening project that will likely reduce nitrogen removal requirements. Design of the culvert is close to complete and construction was scheduled to begin in fall 2015. The project received two federal grants - $3.4 million of Hurricane Sandy Mitigation and Resiliency funding and a $1 million National Coastal Wetlands Conservation grant - and spring 2014 Town Meeting approved the appropriation of an additional $1.75 million.

A more detailed chronology of water quality planning efforts in Harwich is available in Appendix 2J.

MASHPEE

The Mashpee CWMP was scoped through a joint MEPA/DRI review as an ENF in 2001. In 2007, the town submitted its Needs Assessment Report entitled, "Town of Mashpee, Popponesset Bay and Waquoit Bay-East Watersheds Needs Assessment Report." The report documents the significant level of effort that has gone into determining the nitrogen TMDLs for the two subject embayments over the course of six years. Also in 2007, the town completed a technology screening report, which was followed shortly by its draft alternative scenarios and site evaluation report in March 2008.

Mashpee has been engaged in numerous county, state, and federally funded projects, including the 2009 MassDEP Pilot Project and the 2009 Cape Cod Commission TMDL Implementation Project, which were both funded by US EPA. Through these projects, the town ran a number of scenarios through the MEP linked water quality model to evaluate TMDL compliance strategies, including an assessment of cranberry bogs and streams for potential additional natural attenuation. These projects also allowed Mashpee, together with representatives of Barnstable and Sandwich, to participate in the determination of nitrogen allocation for Popponesset Bay for each town and prepare a draft intermunicipal agreement. Mashpee received wastewater grant funds from Barnstable County to model sewer collection systems in the Popponesset watershed and technical assistance from the USGS and Commission staff to use the Sagamore Lens groundwater model to evaluate potential wastewater disposal sites.

The Needs Assessment contains a characterization of the nine operating private sewage treatment facilities, including treatment efficiency and excess capacity. This work allowed the town to focus on three potential wastewater scenarios that were developed in 2012. These options are being reviewed and will be the basis for development of their preferred alternative. The wastewater scenarios include use of the existing private plants at their planned capacity and either three or four subregional plants with consideration of shared town responsibility. Off-site disposal of effluent outside of the impaired watersheds is an important consideration for the plan's approach. The alternatives analysis included consideration of private effluent disposal sites at New Seabury, Willowbend, and others, in addition to the town's transfer facility site.

The town has an appointed seven-member Sewer Commission and an in-house coordinator for wastewater projects as the town proceeds with selecting a preferred alternative. Special legislation filed by the town to convert the Mashpee Water District to the Mashpee Water and Sewer District was signed by the Governor on April 18, 2014 and is pending approval by Mashpee voters. In addition to the needs and alternatives identified, the town is considering the use of the JBCC treatment facility and disposal site as long-term regional solutions.

In April 2014, the Sewer Commission met with Cape Cod Commission staff to begin the discussion around filing its CWMP. The current draft plan includes a significant aquaculture undertaking and an adaptive management approach to achieving water quality goals. In September 2014, the Massachusetts Secretary of Energy and Environmental Affair issued a certificate of adequacy for the DEIR for Mashpee's Comprehensive Watershed Nitrogen Management Plan.

A more detailed chronology of water quality planning efforts in Mashpee is available in Appendix 2K.

ORLEANS

The Orleans CWMP was approved by MEPA and the Cape Cod Commission in 2011 and provides a strategy for wastewater management to achieve reductions of its share of nitrogen loading to restore and protect Orleans's coastal embayments. The CWMP also addresses freshwater ponds and areas with septic system problems associated with frequent pumping, intensity of use and mounded systems. It provides modest capacity for expanded residential housing in the commercial district and includes an adaptive management approach for its implementation.

The CWMP proposes collection of an annual wastewater flow of 0.64 MGD from 2,800 properties to serve 53% of the town. The project would be implemented in six phases over a 15-20 year period of implementation.

The phased sewer plan also accommodates septage and sludge handling and proposes five small package-treatment systems that will hasten nutrient removal for subwatersheds to Pleasant Bay as the plan is phased in. The phased plan also targets nutrient reduction through non-structural elements, including a fertilizer control program, stormwater management, a water conservation

program coupled with a wastewater flow- and load-reduction initiative, enhancement of embayment flushing, and land use controls.

The estimated cost of the CWMP is $150 million (in 2008 dollars) over the 15-20 year implementation period. The average cost to a homeowner is estimated at $2,600 per year. The town has adopted a cost-recovery policy that incorporates property tax assessment to pay for 80% of the costs and relies on betterments for the remaining 20%.

The town asked the Cape Cod Commission staff to participate in reviewing the needs assessment, alternatives assessment, and preferred alternative reports prior to their formal submittal as a DEIR/ENF in 2009. As part of its CWMP process, Orleans took advantage of a Cape Cod Water Protection Collaborative grant to examine potential cost savings that could be realized if the planned Orleans wastewater facility were shared with the towns of Brewster and/or Eastham. The resulting study, entitled "Wastewater Regionalization Study: Orleans-Brewster-Eastham," was released in December 2009. The study identified a potential 6-9% savings in capital costs, and an 18-25% savings in operation and maintenance (O&M) costs resulting from a shared facility.

The town received its MEPA certificate on the FEIR and a DRI approval in 2011. The town has since engaged independent consultants to review the use of alternative sewer collection technologies and the Massachusetts Estuaries Project findings about the Nauset Marsh. The town received significant input from the community as the board of selectmen considers its appropriate next steps.

The Orleans CWMP DRI approval contained several conditions related to the potential of operating the Orleans facility as a shared municipal facility. The Town of Orleans agreed to meet with Brewster and Eastham representatives to discuss potential regionalization options and report to the Commission on the status of those discussions. The DRI decision also directs the Town of Orleans to keep options open for sharing the proposed facility, as well as disposal capacity at the facility, for a finite period of time. The intent of this condition was to create an opportunity for the three towns to pursue a shared facility, while allowing Orleans to proceed with its single town plan in a reasonable time frame.

Another regional issue raised by the Orleans CWMP is that the proposed Orleans wastewater facility will discharge into the Nauset Marsh system, which has assimilative capacity for nitrogen. The Town of Brewster expressed concern about the potential for Orleans to use up this assimilative capacity, leaving Brewster with fewer disposal alternatives as it develops its own management plan. The DRI decision capped the amount of assimilative capacity that may be used by Orleans in order to address this concern.

Funds for design and construction of the Orleans CWMP, or phases within the CWMP, have not yet been appropriated by Town Meeting.

Spring 2014 Town Meeting approved an extension of the three-town agreement with Eastham and Brewster through 2016 to run the Tri-Town Septage Treatment Facility. Town Meeting also approved an appropriation of $1.045 million to fund several projects with a collective purpose to produce information necessary to further shape water quality improvement projects in town. Specifically, the appropriated funds will be used for engineering, planning and hydrogeologic studies necessary for the development of septage, wastewater, groundwater and stormwater management plans needed to maintain and protect the water resources of the town by integrating the CWMP with a new Adaptive Management Plan and components of the Cape-wide Section 208 Water Quality Management Plan.

A more detailed chronology of water quality planning efforts in Orleans is available in Appendix 2L.

PROVINCETOWN

Provincetown completed a WWFP in 2001. The plan dealt with the public health issues of failing septic systems and inadequate infrastructure for its commercial downtown area. The comprehensive plan was approved by state agencies through MEPA and by the Cape Cod Commission through DRI review in 2001. The wastewater facility and phase 1 and 2 areas were subsequently built and are performing well. The plan included a number of innovative aspects, including a lot-by-lot assessment of Title 5 systems, use of the Route 6 median and right-of-way for effluent disposal, combination of force mains, conventional gravity and vacuum sewers, and "checkerboard" sewer areas. The plan included three phases. The town is presently expanding sewers into the Phase 3 area and is upgrading the facility to its planned capacity. During this implementation, the town was able to use measured

wastewater flow to compare to the design capacity and to negotiate the use of that excess capacity for new wastewater flow.

A more detailed chronology of water quality planning efforts in Provincetown is available in Appendix 2M.

SANDWICH

The town of Sandwich has established a water quality committee to oversee water quality and wastewater planning efforts. The committee developed a scope of work for a CWMP and submitted the scope under the Sagamore Lens Natural Resource Damages Assessment, related to past groundwater contamination at the Textron facility at the Joint Base Cape Cod (JBCC). The town received an award of $400,000 t0 conduct its water/wastewater plan and completed a comprehensive needs assessment, as well as an interim wastewater solutions plan to accommodate economic development in the South Sandwich Village Center (often referred to as the Golden Triangle area).

The town spent several years working with a private developer on a development project that included a public-private wastewater component involving the construction of a facility that would accommodate the private project and a certain amount of general public wastewater need. That project will not be completed, but the town is again seeking a private partner to create new economic growth and to potentially participate in infrastructure development.

The town is participating in discussions at JBCC about the potential use of its existing wastewater infrastructure as a regional option for the Upper Cape towns.

A more detailed chronology of water quality planning efforts in Sandwich is available in Appendix 2N.

TRURO

The town of Truro approved funds for a CWMP, acknowledging that protection of private-well drinking water is of paramount importance, and established a water resources oversight committee. The CWMP kicked off in 2012 with a focus on septic systems and stormwater-runoff and their impact on drinking water and embayment water quality. The planning process seeks to assemble existing data, and develop a GIS program to evaluate land and water data, historic septic-system management information and key areas for further analysis and characterization. The committee is in the process of reviewing the phase 1 of the draft water management plan.

A more detailed chronology of water quality planning efforts in Truro is available in Appendix 2O.

WELLFLEET

The town of Wellfleet has an established Comprehensive Wastewater Management Planning Committee that is charged with providing a comprehensive strategy for addressing wastewater treatment and disposal issues for the next 40 years and for the foreseeable build out conditions in town. Along with its consultant, the town completed a draft of its CMWP Needs Assessment and Alternatives Analysis reports in June 2012. The objectives of the CWMP are to protect and enhance the Wellfleet Harbor ecosystem, promote aquaculture-based water quality management solutions, identify low-cost and sustainable remedies, develop least-cost alternatives and, only as a final resort, engage in structured solutions.

The CWMP process allowed Wellfleet to pursue and implement pilot scale ecotoilet and oyster restoration solutions (see Chapter 4 for technology descriptions). Spring 2013 Town Meeting appropriated funds to build a bathhouse at Bakers Field Beach that uses composting toilet technology to reduce the nitrogen load to Wellfleet Harbor. The oyster restoration project is a 2-acre site in Wellfleet Harbor and has a well-structured monitoring component. Water quality monitoring was conducted at the site in 2012 and 2013 and provided necessary data for the town to make informed decisions moving forward.

A more detailed chronology of water quality planning efforts in Wellfleet is available in Appendix 2P.

YARMOUTH

The town of Yarmouth's wastewater committee began its work in 2003. In 2010, the town submitted its CWMP as a DEIR. The draft CWMP targeted areas that would require wastewater collection to restore water quality in the Lewis Bay and Parkers River watershed and deal with the Title 5 constraints on economic redevelopment in the area of Route 28. The town's plan included approximately 125 miles of sewer lines and the collection of 2.75 MGD of wastewater to

be treated at a single facility in the Parkers River watershed. The project would ultimately serve 9,580 properties by 2035. Phase 1 of the plan would begin with the treatment facility and main trunk line sewer to serve Route 28 and portions of the Parkers River and Lewis Bay watershed.

The town submitted its FEIR and received MEPA approval in July 2011, but did not complete the DRI process before going to September 2011 Town Meeting to seek Phase 1 design and construction funds. Phases 1 through 5 were scheduled to be implemented over a 25-year period. The estimated cost of the total plan was $275 million. The first phase had an estimated cost of $55 million. Town Meeting did not approve the expenditure. The town withdrew the CWMP from the DRI review process and is evaluating the next appropriate steps.

Yarmouth officials have been meeting with Cape Cod Commission staff, MassDEP and Barnstable officials to discuss the scoping of a targeted watershed approach for Lewis Bay.

A more detailed chronology of water quality planning efforts in Yarmouth is available in Appendix 2Q.

Existing Wastewater Infrastructure

There are four communities with municipally owned and operated wastewater treatment facilities on Cape Cod. In addition, there are a number of small and privately owned and operated facilities located throughout the region.

What follows is a brief summary of the existing municipal infrastructure, including information on current treatment and disposal capacity. Future analysis of potential expansion capacity of the existing municipal facilities may benefit Cape Cod communities looking for affordable solutions to collect and treat wastewater. The existing infrastructure located in and serving Joint Base Cape Cod is discussed in Chapter 7.

The four communities currently operating municipal wastewater treatment facilities are Barnstable, Chatham, Falmouth and Provincetown.

BARNSTABLE

The Hyannis WPCF, located off Bearses Way in Hyannis, is the primary facility serving the town. It has a permitted capacity of 4.2 MGD that is discharged on-site through open sand beds. In addition to the on-site discharge capacity, the town of Barnstable acquired the "McManus" site on Route 132 in 2002 to potentially accommodate future flows; however, this site is not being used today.

Current operating conditions at the facility treat an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluence and the facility has a discharge limit of 10 mg/L. The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The town of Barnstable also operates two smaller facilities - the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 GPD and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes.

CHATHAM

The Chatham WWTF, located on an 80-acre parcel on Sam Ryder Road, recently underwent a major upgrade as part of phase 1 CWMP. The facility has a permitted capacity of 1.0 MGD (annual average) and 2.3 MGD (peak day) and two existing sand beds, which have been in operation for 35 years. The permit requires a discharge limit of 10 mg/L with an annual limit of 9.132 pounds/year, which corresponds to an annual average discharge of 3 mg/L.

The upgrade to the WWTF included several improvements to its sludge processing capabilities. Dewatered sludge is discharged and taken off site for disposal. The site also accepts septage collected from Chatham parcels only.

FALMOUTH

The Falmouth WWTF, located on Blacksmith Shop Road, was upgraded from a lagoon treatment process to include Sequencing Batch Reactors (SBR) and denitrification filters in 2005. The facility is currently permitted with an effluent flow restriction of 0.8 MGD. The permit limits flows to the WWTF to 0.23 MGD inside the West Falmouth Harbor watershed and 0.57 MGD outside the West Falmouth Harbor watershed. On January 10, 2014 the town received a Certificate of Adequacy from the Secretary Of Energy and Environmental Affairs to sewer the Little Pond Service Area and discharge up to 260,000 GPD at a new disposal site is being pursued ("Site 7"), north of the existing beds and outside the West Falmouth Harbor watershed. The town is moving forward with a new effluent measuring system and optimization and improvement to the existing treatment system including the sludge thickening process at the facility.

PROVINCETOWN

The Provincetown WWTF is an advanced secondary treatment plant that is capable of treating a maximum daily flow (MDF) of 650,000 GPD, with discharge to four subsurface disposal beds at six locations along Route 6. Additional upgrades may be required to increase the capacity to allow a MDF of 750,000 in the future, and will occur when required.

Provincetown is currently working to design, permit, expand, and operate its wastewater collection, treatment and disposal systems.

The current sludge management plan includes periodic removal from the SBRs, storage for aeration and mixing, and hauling by a contractor for disposal at a facility in Cranston, RI.

03 POLICY

Regulations

Advancements in the sciences of marine ecosystems and hydrogeology have helped improve understanding of ongoing impairments as well as establish new standards for coastal water quality, but the language and enforcement tools contained in important water quality statutes are imperfect solutions to today's problems.

The Clean Water Act was effective in stopping direct discharge water pollution and Massachusetts Title 5 regulations successfully protect public drinking water supplies from septic system pollution, but neither is well suited to address coastal nutrient pollution on Cape Cod. The Clean Water Act, as applied, does not regulate discharges on Cape Cod and Title 5 allows septic systems with nitrogen levels in effluent that degrades water quality in embayments.

REGULATORY STREAMLINING

The current permitting and regulation framework is a one-size fits all approach with little consideration for shared watershed permitting and regulation across municipal lines. What's recommended provides a necessary evolution of this framework to successfully implement established federal and state water quality goals.

TARGETED

A permitting approach that allows Targeted Wastewater Management Plans reduces upfront planning time, lowers cost and focuses attention where it's needed.

REDUCTION CREDITS

Towns should get credit for what they are already doing. Policies to reduce fertilizer use and stormwater runoff, supported by performance monitoring, should lower watershed nitrogen reduction targets.

WATERSHED PERMIT

Under the watershed permit approach, nitrogen loads are allocated on a watershed-by-watershed basis, as developed through the Waste Treatment Management Agency, or WMA, designations. The watershed permit will list all technology options identified for implementation by stakeholders for the particular watershed, as well as each permittee's specified annual discharge limit.

Regulating the Problem v. Regulating the Solution

Septic systems are the primary wastewater management infrastructure tool on Cape Cod, with limited groundwater discharges from four (Barnstable, Chatham, Falmouth, and Provincetown) publicly owned treatment works (POTWs) and 58 of smaller wastewater treatment works. These discharges are managed by a one size fits all approach with little consideration for shared watershed permitting and regulation across municipal lines. Wastewater management plans with traditional technologies have clear but often lengthy and extensive permitting paths while alternative technologies are often not permitted or their nitrogen reduction performance is poorly understood and not applied to meeting overall watershed nitrogen management goals and standards.

An inescapable conclusion of the Section 208 Plan Update is that the current regulatory scheme is ill suited to result in effective solutions to the water quality challenges of Cape Cod and that reform is necessary for effective and affordable outcomes to be realized. The recommendations

History of the Clean Water Act

The Federal Water Pollution Control Act of 1948 was the first major U.S. law to address water pollution. Growing public awareness and concern for controlling water pollution led to sweeping amendments in 1972, when the law became commonly known as the Clean Water Act.

The 1972 Amendments:

- Established the basic structure for regulating pollutants discharges into the waters of the United States.
- Gave US EPA the authority to implement pollution control programs such as setting wastewater standards for industry.
- Maintained existing requirements to set water quality standards for all contaminants in surface waters.
- Made it unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a permit was obtained under its provisions.
- Funded the construction of sewage treatment plants under the construction grants program.
- Recognized the need for planning to address the critical problems posed by nonpoint source pollution.

Subsequent amendments modified some of the earlier provisions. Changes in 1987 phased out the construction grants program, replacing it with the State Water Pollution Control Revolving Fund, more commonly known as the Clean Water State Revolving Fund.

For more information: www2.epa.gov/laws-regulations/history-clean-water-act

that follow suggest a necessary evolution of the tools and established regulatory framework to successfully implement federal and state water quality goals to protect and restore coastal waters, while providing flexibility and certainty in the permitting path for local decision makers.

Regulating the Problem: Existing Regulation and Permitting

FEDERAL REQUIREMENTS AND GOALS

FEDERAL CLEAN WATER ACT

The United States Environmental Protection Agency (US EPA) regulates water quality under the federal Water Pollution Control Act of 1972 and its subsequent amendments in 1977, 1981, and 1987. Collectively these are known as the Clean Water Act (CWA) (see http://www.epw.senate.gov/water.pdf for the full Clean Water Act). The objective of the act is to maintain and restore the chemical, physical and biological integrity of US waters. The act requires states to establish ambient water quality standards for water bodies based on the need to protect the use(s) designated for that water body.

The CWA provides the umbrella for the planning, permitting and financing of water pollution control facilities nationally. As a national tool, it deals in broad strokes with the causes of water quality impairment as they were understood at the time of passage and subsequent amendment of the Act. The law has not been updated to address the diffuse and nonpoint nature of water quality problems experienced on the Cape in mind and, as a result, is an imperfect tool for devising and implementing solutions scaled to Cape Cod.

Clean Water Act Section 208

A cornerstone, but rarely still utilized portion of the CWA is Section 208. This section provides the template for areawide waste treatment management plans, like this one, that form the blueprint for attainment of water quality goals within a given region. Plans prepared pursuant to Section 208 of the Clean Water Act must include, in pertinent part, identification of treatment works necessary to meet anticipated waste treatment needs of the area over a 20-year period; establishment of construction priorities and time schedules for the treatment works; establishment of a regulatory program; identification of those agencies necessary to construct, operate and maintain all facilities required by the plan; identification of measures necessary to carry out the plan, including financing and the economic, social, and environmental impact of carrying out the plan; a process to identify construction activity related sources of pollution and to set forth procedures to control such sources; a process to control the disposition of all residual waste that could affect water quality; and a process to control the disposal of pollutants within such area to protect ground and surface water quality.

Section 208 also requires states, as part of the certification process, to designate one or more Waste Treatment Management Agencies (WMAs). WMAs have specific responsibilities articulated in the CWA, including the ability to build and operate treatment works and technologies outlined in their watershed plan to achieve Total Maximum Daily Load (TMDL) compliance, but also issue bonds and notes to raise revenues to carry out their plan. See Chapter 8 for more information on WMAs.

Point and Nonpoint Source Water Pollution

A “point source” of pollution is defined in §502(14) of the federal Clean Water Act as “any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged.” Point sources are regulated by National Pollutant Discharge Elimination System (NPDES) permits.

The term “nonpoint source” is defined as any source of water pollution that does not meet the above legal definition of a “point source.” Nonpoint sources are typically described as those emanating from precipitation that has picked up natural and human-made pollutants as it moves over and through the ground. The US EPA lists fertilizers, herbicides, pesticides, oil and grease, sediments and bacteria and nutrients as examples of nonpoint source pollutants. Septic systems, despite the fact that they introduce nutrients and other contaminants into the groundwater are considered non-point sources of pollution and are therefor not regulated by US EPA.

Regulations and Enforcement

At the present time, there is no federal law that requires the regulation of nonpoint source water pollution in a way that gives rise to enforcement actions. Given the scope of the CWA and the nature of wastewater management on the Cape, US EPA permit requirements do not apply to Cape Cod and the reach of the CWA on Cape Cod is limited to planning and the development of TMDLs for impaired waters.

Cape Cod has recently been the subject of a lawsuit on this issue in the matter of Conservation Law Foundation (CLF) and the Buzzards Bay Coalition (BBC) v. the United States Environmental Protection Agency et al. The original lawsuit asserted that the US EPA violated the Clean Water Act and its regulations by failing to properly regulate nonpoint sources resulting in increased nitrogen levels which have degraded the embayments in a manner that has injured the recreational, commercial and aesthetic interests in those waters. This lawsuit was dismissed for lack of standing, leaving the underlying claims of the plaintiff unresolved by the courts

In a refiled suit, CLF asserted that the US EPA's mandatory annual review of how Massachusetts administers its State Revolving Fund (SRF) has been contrary to law. Specifically, under the Clean Water Act, the US EPA has the authority to grant money to a state's SRF fund for certain types of wastewater management projects subject to certain restrictions on the use of the funds, with the main one being that funded projects be consistent with approved 208 plans. The US EPA has a duty to review a state's plans and reports concerning the state's use of those funds on an annual basis.

CLF sought an injunction requiring that (1) the US EPA notify the Commonwealth of its noncompliance; and (2) an update to the Section 208 Area Wide Water Quality Management Plan be completed within one year. The US EPA sought and received a stay of this lawsuit until June 1, 2015, pending review and approval of this updated Cape Cod area wide water quality management plan under Section 208 of the Clean Water Act.

Subsequently, on November 17, 2014, CLF and US EPA filed a settlement agreement in US District Court requesting an extension of the existing stay of the Section 208 Action from June 1, 2015 to September 15, 2015, a stay of the TMDL Action until September 15, 2015, and a dismissal of both actions upon completion of a series of actions to be completed by EPA, including the approval of the Cape Cod Section 208 Plan Update.

While the lawsuit sought to change this, direct federal regulation of large nonpoint source water pollution is managed today through non-regulatory means, including assistance to states from federal planning and grant programs under the Clean Water Act. Among the non-regulatory strategies this plan tries to leverage are watershed and land use planning, development of voluntary best management practices, technical assistance programs regulatory reform and cost-sharing for implementation of prevention and control measures.

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) STORMWATER PERMIT PROGRAM AND MUNICIPAL SEPARATE STORM SEWER SYSTEMS (MS4)

The Clean Water Act authorizes US EPA and states to regulate point sources that discharge pollutants into waters of the United States through the National Pollutant Discharge Elimination System permit program. These "point sources" are generated from a variety of residential, municipal and industrial operations, including treated wastewater, process water, cooling water, and stormwater runoff into drainage systems. The NPDES Stormwater Program regulates discharges from certain municipal separate storm sewer systems (MS4s), construction activities, and industrial activities. The US EPA Regional Administrator may also designate needed stormwater controls for discharge based on waste load allocations that are part of a TMDL that address the pollutant of concern. See 40 CFR §122.26(a)(9)(i)(C) and (D)(relating to discharges that the Regional Administrator determines are a significant contributor of pollutants or contribute to a violation of water quality standards).

On Cape Cod, all communities except Truro and Provincetown are expected to be subject to newly issued regulation under the MS4 permit program.

The Clean Water Act provides that municipal and industrial stormwater permits "shall require controls to reduce the discharge of pollutants to the maximum extent practicable,

including management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants" CWA Section §402(p)(3)(B)(iii).

Municipalities not only have to control pollutants to the maximum extent practicable, but also have to effectively prohibit non-stormwater discharges into the system and comply with provisions as deemed by the Regional Administrator or, in states with an approved NPDES program, the State Director.

The definition of MS4s includes but is not limited to: stormwater outfalls, roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels, and/or storm drains. The complete definition may be found at 40 CFR §122.26(b)(8).

The Cape communities south and west of Eastham are currently operating under an administrative extension to the 2003 MS4 permit, which remains enforceable and in effect administratively with all of terms and conditions until a new permit is issued. US EPA Region 1 published a 2014 Draft Massachusetts MS4 Permit on September 30, 2014; the comment period for the draft permit closed on February 27, 2015.

The draft Massachusetts MS4 permit has six minimum measures:

- Public education and outreach
- Public involvement
- Illicit discharge detection and elimination
- Construction runoff
- Post construction stormwater management
- Pollution prevention

For more information about the draft permit, see: http://www.epa.gov/region1/npdes/stormwater/MS4_MA.html. In addition, US EPA anticipates issuing a separate small MS4 permit for the Massachusetts Department of Transportation (MassDOT) in the near future.

The 2003 MS4 permit established goals and metrics geared toward improving water quality in water bodies regulated under the Clean Water Act. Municipalities were required to develop, implement, and enforce a stormwater management program designed to control pollutants to the maximum extent practicable in the watershed. The "maximum extent practicable" standard is a flexible goal intended to be met through an iterative process. Municipalities implement their stormwater management programs through best management practices (BMPs), periodically assess the effectiveness of the BMPs, and then make revisions to address ineffective elements of the program, and improve pollutant control.

Presently there are approved TMDLs for nitrogen in many of Cape Cod's coastal embayment systems. The Massachusetts Estuaries Project (MEP) technical reports for Cape Cod watersheds identify MS4 sources as comprising 3%-17% of the controllable watershed nitrogen load, depending on the watershed studied. It has been anticipated that the new permit will contain specific regulations for discharges subject to an approved TMDL to better address specific pollutant problems in regulated water bodies.

For the "Cape Cod Nitrogen TMDL's," the 2014 draft Massachusetts MS4 permit seeks nitrogen reduction through enhanced Best Management Practices for discharges to nutrient impaired waters or their tributaries, with a focus on public education, new development/redevelopment and good housekeeping. For discharges to waterbodies without an approved TMDL, there are still requirements for bacteria, nutrients, solids, chloride, metals and oils and grease. A Nutrient Source Identification Report, which is due on year four from the date of the issuance of the permit, seeks the delineation of potential nitrogen or phosphorus sources, an identification of potential retrofits, one demonstration project by year six, and the tracking of nitrogen or phosphorus reductions through the implementation of structural BMPs.

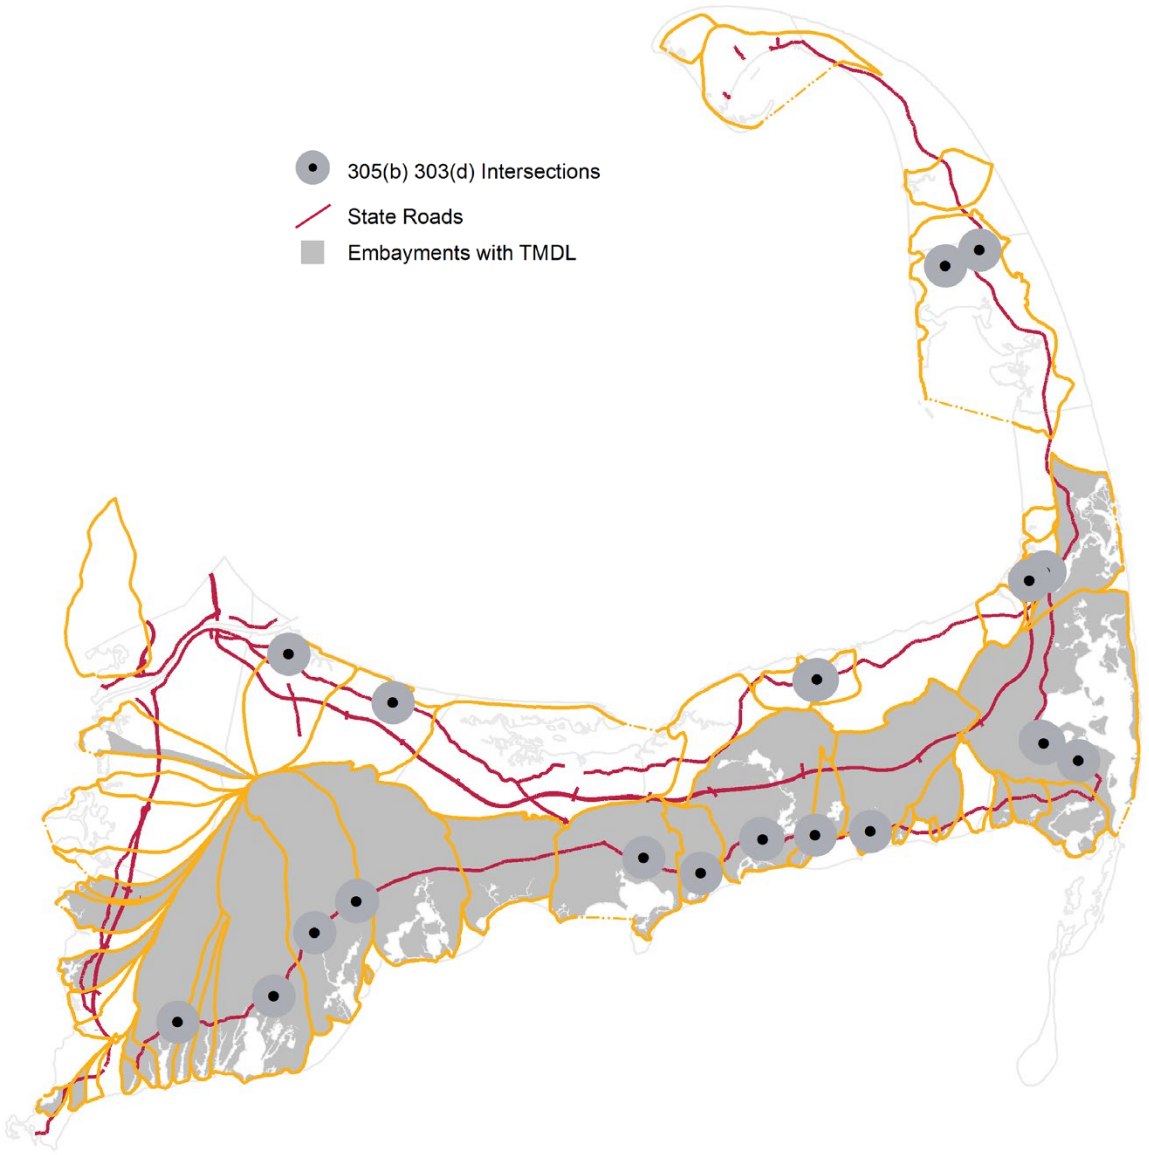
Towns should be prepared to respond to the draft small MS4 general permit soon after its issuance. To seek coverage under the small MS4, towns must file a Notice of Intent (NOI) within 90 days of US EPA's issuance of the final MS4 permit following the public comment period. Requirements for the NOI filing include: the location of the current Stormwater Management Program (website or physical address), status of outfall map, a summary of the status of relevant bylaws/ordinances, identification of the number of outfalls contributing to receiving waters and a summary of the current Stormwater Management Program.

MassDOT is recognized as a regulated entity with a separate individual small MS4 permit anticipated to be released in the near future. State roadways operated by MassDOT in watersheds to impaired water resources also contribute nutrients and other pollutants from stormwater. **Figure 3-1** shows the state roadways that intersect water resources with completed TMDLs for nitrogen, are pending MEP analysis, and/or are listed on §305(b) or §303(d) Integrated List of Waters. See Chapter 7 for specific recommendations for working with MassDOT to improve stormwater management on state roadways.

For more information about the MS4 Permit Program, see http://epa.gov/region1/npdes/stormwater/. Chapter 6 provides a discussion of stormwater utilities as a means of raising stable and adequate revenue to fund stormwater improvements and maintenance.

NPDES AUTHORITY

The CWA allows the US EPA to authorize the NPDES Permit Program to state governments, enabling states to perform many of the permitting, administrative, and enforcement aspects of the NPDES Program. Currently, the US EPA has authorized all but five states to participate in some capacity in the administration and enforcement of NPDES permits. Massachusetts is not a delegated state under the NPDES permit program. NPDES permits are jointly issued by the US EPA and the MassDEP and are equally and separately enforceable by both agencies. Presently, there are various methods used to monitor NPDES permit conditions. According to the US EPA, these include the following:



2012 Integrated List of Waters 305(b) 303(d)

Figure 3-1

- The permit requires the facility to sample its discharges and notify US EPA and the state regulatory agency of its results.
- The permit also requires a facility to notify US EPA and the state regulatory agency when the facility determines it is not in compliance with the requirements of a permit.
- US EPA and state regulatory agencies also send inspectors to companies in order to determine if they are in compliance with the conditions imposed under their permits.

Federal law provides US EPA and authorized state regulatory agencies with various methods of taking enforcement actions against violators of permit requirements. These include the authority for US EPA and state regulatory agencies to issue administrative orders requiring facilities to correct violations and assess monetary penalties. The US EPA and state agencies may also pursue civil and criminal actions that may include mandatory injunctions or penalties, as well as jail sentences for persons found willfully violating requirements and endangering the health and welfare of the public or environment.

To the extent a locally proposed solution results in the need for a NPDES permit, providing the Commonwealth of Massachusetts permitting and enforcement abilities that the majority of the United States currently exercise will enable the locality to pursue the streamlined process that the Section 208 Plan proposes. Delegating such authority to the Commonwealth of Massachusetts in conjunction with its newly produced action plan pursuant to Section 208 is in line with its proposal and it's consideration is recommended as part of this plan.

Recommendation R3.1: The Commonwealth of Massachusetts should seek delegated authority under the Clean Water Act to issue and enforce NPDES permits.

REQUIREMENTS AND GOALS

The lack of direct federal NPDES permitting on Cape Cod means that much of the regulatory load is carried by the Commonwealth of Massachusetts through the Department of Environmental Protection (MassDEP). Wastewater discharges are currently regulated in the Commonwealth through the following means:

- **SEPTIC SYSTEMS:** Regulation of septic systems is delegated by the state to municipalities under the jurisdiction of the Boards of Health in each city or town in accordance with 310 CMR 15.000 (Title 5). The BOH role is to ensure that the systems are installed and maintained according to code.
- **GROUNDWATER DISCHARGES (VOLUMES OVER 10,000 GALLONS PER DAY):** MassDEP issues Groundwater Discharge Permits for facilities that discharge to the ground. At a minimum, these permits require secondary treatment with a nitrogen limit of 10 milligrams per liter (mg/l) before discharging to the ground. Groundwater discharge permits are prominent on Cape Cod.
- **SURFACE WATER DISCHARGES (NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM [NPDES] PERMIT):** MassDEP issues these permits jointly with the US EPA. These permits for discharge to surface waters have end of the pipe effluent limits for pollutants of concern, like nitrogen and phosphorus, which comply with the surface water quality standards.

These permitting processes are part of a set of regulatory programs that, taken together, provide a framework of tools to manage, somewhat imperfectly, the water quality challenges facing Cape Cod. There is no single regulatory program with the scope and authority to successfully manage Cape Cod waters, so these separate programs and tools must be woven together, reformed and used in new ways.

STATE TITLE 5 REGULATIONS ON WASTEWATER FLOWS

MassDEP regulates wastewater flows less than 10,000 gallons per day under 310 CMR 15.000: The State Environmental Code, Title 5: Standard Requirements for the Siting, Construction, Inspection, Upgrade and Expansion of On-Site Sewage Treatment and Disposal Systems and for the Transport and Disposal of Septage (typically referred to as Title 5). Title 5 typically covers such uses as conventional on-site septic systems, alternative systems, such as denitrifying systems (often called "Innovative/ Alternative," or I/A, systems), as well as composting toilets

and other kinds of systems in use on individual properties or cluster developments. Title 5 presumes residential wastewater flows at 110 gallons per day per bedroom (e.g., Title 5 presumes that a four-bedroom house will generate 440 gallons per day, and that one 440 gpd septic system per acre is protective of drinking water quality). Non-residential wastewater generation is typically based on use and square footage, or for example, the number of restaurant seats.

MASSACHUSETTS GROUND WATER QUALITY STANDARDS

Massachusetts Groundwater Quality Standards

Massachusetts applies a number of regulations protective of groundwater, many of which are also protective of surface waters because contaminants affecting groundwater quality, e.g. nitrogen, ultimately discharge to surface waters. Massachusetts Groundwater Quality Standards, 314 CMR 6.00, were rescinded in 2009 because revisions to 314 CMR 5.00 eliminated the need for this regulation.

Primary regulations protective of groundwater include:

- Drinking Water Regulations (310 CMR 22.00)
- Groundwater Discharge Program (314 CMR 5.00)
- Septic System regulations (310 CMR 15.00; Title 5)
- Land Application of Sludge and Septage Wastewater & Sewer Regulations (310 CMR 32.00)
- Supplemental Requirements for Hazardous Waste Management Facilities (314 CMR 8.00)
- Reclaimed Water Regulations (314 CMR 20.00)
- Wetlands Protection Act Regulations (310 CMR 10.00, including the Massachusetts Stormwater Policy and Guidelines)
- Massachusetts Contingency Plan (310 CMR 40.0000)

GROUNDWATER DISCHARGE PERMITS

Flows in excess of 10,000 gallons per day are regulated under the state Groundwater Discharge Permit Program (See 314 CMR 5.00 Groundwater Discharge Permit Program). Systems requiring a groundwater discharge permit require significant removal of nitrogen because the Cape Cod Aquifer is designated as a non-degradation resource. Groundwater discharge permits for Cape Cod require an effluent treatment level of at least 10 milligrams per liter of nitrate, which is almost a two-thirds reduction in the amount of nitrogen leaving a septic system, although not low enough to achieve or maintain marine water quality. In the last 10 years, groundwater discharge permits for projects located in watersheds to nitrogen impaired embayments have been held to a "no-net nitrogen" standard by MassDEP. This means that any nitrogen released into the watershed must be "offset" by the removal of nitrogen from an existing source. To date, this typically occurs by connecting a nearby existing development to remove nitrogen via wastewater treatment.

MASSACHUSETTS SURFACE WATER QUALITY STANDARDS

Following federal law, and as prescribed by the federal Clean Water Act, the Commonwealth of Massachusetts adopted surface water quality standards for individual water bodies. The standards designate the most sensitive uses for which the water body must be "enhanced, maintained, and protected" (whether or not the designated use is currently attained), prescribe minimum water quality criteria necessary to sustain the designated uses and contain the regulations necessary to achieve and maintain the designated use and, where appropriate, prohibit discharges.

Massachusetts divides coastal and marine surface waters into three classes: SA, SB, and SC, in descending order of the most sensitive uses that water body must attain. Additionally the state has special designations of Outstanding Resource Waters, Special Resource Waters, Shellfish (waters), and Warm Water. A brief description of these classes and special designations follows. For more information see M.G.L. c. 21, §27. 314 CMR 4.00: Massachusetts Surface Water Quality Standards.

SA Waters are designated as the highest quality, providing excellent habitat for marine life and for primary and secondary contact recreation. In certain waters, excellent habitat may include seagrass and, where designated for shellfishing, SA waters are suitable for shellfish harvesting without depuration (process of removing impurities). Nearly all of the coastal waters of Cape Cod have been classified as SA.

SB Waters are designated as habitat for marine life and for primary and secondary contact recreation. In certain waters, habitat may include seagrass. Where designated for shellfishing, these waters are suitable for shellfish harvesting with depuration. Several water bodies on Cape Cod have been classified as SB waters, particularly those that are used heavily for shipping and boating.

SC Waters are designated as habitat for marine life and for secondary contact recreation. They may also be suitable for certain industrial cooling and process uses. There is no water body on Cape Cod that has been classified as SC.

Outstanding Resource Waters (ORW) denotes waters that "include Class A Public Water Supplies (314 CMR 4.06(1)(d)1) and their tributaries, certain wetlands as specified in 314 CMR 4.06(2) and other waters as determined by the department based on their outstanding socio-economic, recreational, ecological, and/or aesthetic values." An application to nominate a water body as an ORW must be submitted in accordance with applicable department application procedures and requirements. Areas of Cape Cod that have been designated as ORW include waters within and adjacent to the Cape Cod National Seashore and Areas of Critical Environmental Concern (ACECs). See Appendix 3A for a list of ACECs.

Shellfishing Waters are subject to more stringent regulation in accordance with the rules and regulations of the Massachusetts Division of Marine Fisheries.

Warm Waters are those waters in which the dissolved oxygen and temperature criteria for warm-water fisheries apply. This designation applies only to fresh water bodies.

There is a provision to remove a designated use through a Use Attainability Analysis (UAA) persuant to 40 CFR 131.10(g). The towns of Eastham and Orleans have begun discussions with the state regarding an UAA for Rock Harbor.

IMPAIRED WATERS AND TOTAL MAXIMUM DAILY LOADS

Massachusetts submits a list of the conditions of surface waters to the US EPA every two years in compliance with the Clean Water Act. The "Integrated List of Waters" identifies each water body or segment of a water body as supporting a designated use or as impaired. With the Integrated Report option, US EPA encourages states to use a five-category system for classifying all water bodies (or segments) within its boundaries regarding the waters' status in meeting the state's water quality standards. The categories are listed below in **Table 3-1**. The classification system uses designated uses as the basis for reporting on water quality.

The waters from Category 5 constitute the Section 303(d) list of impaired or threatened waters within the State boundaries. In addition to the 303(d) report, the CWA requires that each state report every two years on the health of all its waters, not just those that are impaired. Information from this report, known as the 305(b) report or "biennial water quality report," has historically been used

CATEGORY/SUBCATEGORY	DESCRIPTION
Category 1	All designated uses are supported, no use is threatened.
Category 2	Available data and/or information indicate that some, but not all, designated uses are supported.
Category 3	There is insufficient available data and/or information to make a use support determination.
Category 4	Available data and/or information indicate that at least one designated use is not being supported or is threatened, but a TMDL is not needed.
Category 4a	A State developed TMDL has been approved by US EPA or a TMDL has been established by US EPA for any segment-pollutant combination.
Category 4b	Other required control measures are expected to result in the attainment of an applicable water quality standard in a reasonable period of time.
Category 4c	The non-attainment of any applicable water quality standard for the segment is the result of pollution and is not caused by a pollutant.
Category 5	Available data and/or information indicate that at least one designated use is not being supported or is threatened, and a TMDL is needed.

Five Category System for Classifying Waterbodies

Table 3-1

to develop the "threatened and impaired waters" list. Most states compile the data and findings from the 305(b) report and add information from other sources, such as the state's report of waters affected by nonpoint sources (CWA §319), to produce the 303(d) list. EPA recommends that states combine the threatened and impaired waters list, 303(d) report, with the 305(b) report to create an "Integrated Report," due April 1 of even-numbered years.

The most recent impaired waters list for Massachusetts, including Cape Cod waters, is the Massachusetts Year 2012 Integrated List of Waters. As of the date of this report, the Massachusetts Year 2014 Integrated List of Waters is still considered draft.

The Clean Water Act, under §303(d), requires states to assess the quality of surface waters based on the intended uses identified in the state Water Quality Standards on a regular basis and to develop a list, referred to as the 303(d) list, of impaired waters detailing those waters that do not meet the intended uses. The Clean Water Act requires all states to submit for US EPA approval every two years on even-numbered years a list of impaired and threatened waters. The states identify all waters where required pollution controls are not sufficient to attain or maintain applicable water quality standards, and establish priorities for development of TMDLs based on the severity of the pollution and the sensitivity of the uses to be made of the waters, among other factors. States then provide a long-term plan for completing TMDLs within 8 to 13 years from first listing.

Under §303(d) of the Clean Water Act, states are required to:

- Identify those water bodies that are not expected to meet the Surface Water Quality Standards from technology-based controls; and,
- Establish, subject to US EPA approval, for those water's TMDLs—the maximum amount of a pollutant from any source and of any kind that a water body can have without violating water quality standards.

On Cape Cod, state-developed TMDLs are based on technical reports prepared by the MEP. TMDLs are formulated by MassDEP and submitted to US EPA for approval after public comment. The TMDLs are utilized as the standards MassDEP and other regulatory authorities use to determine whether their regulations are met as required by the Federal Clean Water Act.

NONPOINT SOURCE MANAGEMENT PLAN

Massachusetts developed a nonpoint source management (NPS) plan in 1988 pursuant to §319 of the Clean Water Act. This plan, updated most recently in 2014, is an integrated strategy for the prevention, control and reduction of pollution from nonpoint sources. As part of the 2014 update, the MA Office of Coastal Zone Management also updated its Coastal Nonpoint Pollution Program 5-Year implementation Plan and 15-Year Program Strategy, and included it in the statewide plan. Federal funds are available for activities such as technical assistance, education, training, technology transfer, watershed restoration and demonstration projects. Only those implementation strategies identified in the management plan are eligible for federal funding. In addition to the NPS Management Plan, in 2006 MassDEP developed a Clean Water Toolkit (also known as the Massachusetts Nonpoint Source Pollution Management Manual) that provides information about the nonpoint source management measures that can be used in Massachusetts. Both the 2014 Massachusetts Nonpoint Source Management Program Plan and the Toolkit can be found at http://www.mass.gov/eea/agencies/massdep/ for more information.

SAFE DRINKING WATER ACT

The US EPA Primacy Agent for the Federal Safe Drinking Water Act is the MassDEP, Division of Watershed Management's Drinking Water Program. On behalf of the US EPA, MassDEP regulates water quality monitoring, new source approvals, water supply treatment, distribution protection and the reporting of water quality data

The Safe Drinking Water Act (SDWA) is the main federal law that protects the quality of drinking water and the rivers, lakes, reservoirs, springs and groundwater wells that are the source of drinking water. The Act authorizes the US EPA to set standards for drinking water quality to protect against natural and human-caused contaminants and to oversee the implementation of those standards on the state, local and water supplier levels. At present, there are standards that regulate 83 different contaminants. Cape Cod was designated a Sole-Source Aquifer under the Safe Drinking Water Act in 1982.

The Act applies to the more than 170,000 public drinking water systems in the country and requires their evaluation by third party analytical laboratories. The Act does not

cover systems that service fewer than 25 individuals or apply to bottled water. There are 17 SDWA regulated public water suppliers on Cape Cod.

DRINKING WATER AND ZONE II WELLHEAD PROTECTION AREAS

Massachusetts' drinking water regulations (310 CMR 22.00) are intended to protect public health by ensuring that all water used for public consumption is safe, fit and pure to drink. The regulations identify contaminants that must be controlled, establish limits on the allowable concentrations of these contaminants and mandate the type and frequency of monitoring required, ensuring compliance with the regulations.

The regulations define a Zone I as "the protective radius required around a public water supply well or wellfield" and a Zone II as "that area of an aquifer that contributes water to a well under the most severe pumping and recharge conditions that can be realistically anticipated." Zone IIs are also known as wellhead protection areas and all Cape towns have protected them through zoning and Board of Health bylaws. Municipalities identify areas as potential Zone IIs and submit them to the state. Zone I areas are roughly 11 acres large and must be controlled by the public water supplier. Zone IIs are much larger and are subject to protection from the siting of discharges, landfills and other potentially hazardous land uses.

WATER POLLUTION ABATEMENT DISTRICTS

MassDEP may propose the creation of water pollution abatement districts (WPAD) consisting of one or more cities or towns, or designated parts thereof. If MassDEP deems that such a district is necessary for the prompt and efficient abatement of water pollution, it may, after a public hearing, mandate the formation of such a district.

Districts can be proposed by a town or by MassDEP; if it is the latter, a town must take a vote at Town Meeting within 90 days of the nomination. If the town meeting votes against the establishment of a WPAD, MassDEP may hold a hearing with the Water Resources Commission if it finds that the creation of a district is "necessary for the prompt and efficient abatement of water pollution."

Once created, each district is its own independent entity administered by a "district commission." Representatives of the town may comprise the WPAD, but MassDEP may mandate that their agency appoint members (with approval of the Water Resources Commission).

After its creation, the district has one year to present an abatement plan to MassDEP (or a lesser time as established by MassDEP) that contains the source of pollution, the means by which to abate it, and proposed projects for the solution. Once formed, the WPAD may only be dissolved by an act of the Legislature.

The source of authority for WPADs is the Massachusetts Clean Waters Act (M.G.L. c. 21, §§28-30, 32, 35, 36). The Act enables towns to:

- Adopt bylaws/regulations
- Acquire, dispose of and encumber real/personal property (including eminent domain powers)
- Construct, operate and maintain water pollution abatement facilities
- Apportion assessments on the member municipalities
- Issue bonds and notes and raise revenues to carry out the purposes of the district

Member municipalities may then impose assessments on residents, corporations and other users in the district. If a town fails to pay its share, the state may pay it for them out of other funds appropriated to that town.

COMPREHENSIVE WASTEWATER MANAGEMENT PLANS

Currently, individual municipalities develop Comprehensive Wastewater Management Plans (CWMPs) within town boundaries. These plans include watersheds that are both wholly within town boundaries, and watersheds that are shared with a neighboring town. MassDEP considers requests for municipal permits and financing after a state level environmental scoping review is conducted under the Massachusetts Environmental Policy Act (MEPA). MEPA thresholds mandate review for construction and upgrades to wastewater treatment and disposal facilities (MEPA Regulations 301 CMR 11.03 Review Thresholds). Specifically, MassDEP reviews CWMPs under MassDEP "Selection, Approval and Regulation of Water Pollution

Abatement Projects Receiving Financial Assistance from the State Revolving Fund" (310 CMR 44.00). CWMPs have traditionally recommended conventional wastewater sewer collection and treatment facilities, which require a groundwater discharge permit and sewer construction permits. The filing of a CWMP with MEPA typically requires the preparation of an Environmental Impact Report (EIR) which also triggers mandatory regulatory review by the Cape Cod Commission.

The MassDEP Division of Municipal Services Guide to Comprehensive Wastewater Management Planning outlines the process for development of a CWMP. According to the guidance, "The planning exercise requires a community to perform a needs analysis: identifying problem areas including areas with poor soils, areas with failing septic systems and densely developed areas. Different wastewater treatment options including on-site septic systems, decentralized systems, or a centralized community-wide system are also analyzed for applicability in addressing the identified wastewater issues while considering environmental concerns (groundwater recharge, pollution prevention) and costs. Public input is sought throughout the CWMP process."

MEPA AND OTHER STATE PERMITTING REQUIREMENTS

As discussed above, CWMPs typically require MEPA review prior to state and regional permitting. MEPA review involves scoping proposed projects for their potential environmental impacts, identifying alternatives, and avoiding, minimizing or mitigating environmental impacts. CWMPs are typically filed first as an Environmental Notification Form (ENF) or Expanded ENF with a Draft Environmental Impact Report (DEIR) and released for public comment. At the end of public comment, the Secretary of Energy and Environmental Affairs will issue a Certificate of Adequacy that outlines additional information or analysis that should be conducted prior to the next MEPA filing. The final MEPA filing is a Final Environmental Impact Report (FEIR). Upon the Secretary's issuance of a Certificate of Adequacy for an FEIR, appropriate state agencies and the Cape Cod Commission then commence their regulatory reviews (See, 301 CMR 11.). CWMPs typically trigger EIR review because they involve construction of a new wastewater treatment and disposal facility with a capacity of 2,500,000 gallons per day, or because they result in construction of one or more new sewer mains 10 or more miles long. CWMPs may also trigger mandatory EIR thresholds for land and wetland alterations, impacts to endangered or threatened species or archeological sites, and other factors. In addition to MassDEP regulatory review, other state agency permits may include: Massachusetts Natural Heritage and Endangered Species Program; Massachusetts Historical Commission; Massachusetts Division of Marine Fisheries, and others.

Barnstable County Requirements and Goals

CAPE COD COMMISSION

The Cape Cod Commission, the Cape's regional planning agency, was created by an act of the Massachusetts Legislature and ratified by the voters of Barnstable County in 1990 in response to the rapid development pressure of the 1980s. The increased pace of development focused attention on the need to manage growth, guide land use, promote balanced economic growth, provide for adequate capital facilities and infrastructure, and protect environmental resources. The Commission has planning, technical and regulatory tools that can be applied to water quality management on Cape Cod. The Commission has independent statutory authority and is a department within the structure of Barnstable County government.

DRI REVIEW OF MUNICIPAL COMPREHENSIVE WASTEWATER MANAGEMENT PLANS

A Development of Regional Impact (DRI) is a proposed development that is likely to present development issues significant to more than one municipality in Barnstable County. Projects are referred to the Cape Cod Commission for review as DRIs by a variety of means. The Commission is required to review the proposed development and either approve, approve with conditions, or deny the development proposal.

CAPE COD REGIONAL POLICY PLAN

The Cape Cod Commission Act (Act) established a Commission regulatory function to review and approve, condition, or deny development projects that exceed Development of Regional Impact thresholds. The Act includes a provision that the Commission develop and implement a Regional Policy Plan (RPP) that contains the minimum performance standards (MPS) for its regulatory review of proposals. The Commission published the first version of the Regional Policy Plan in 1991; it has been updated and revised every five years.

The initial water resources section of the Regional Policy Plan recognized that many of the Cape's embayments were suffering from water quality impacts associated with nitrogen from septic systems. In the late 1990s the plan's minimum performance standards for development not exceeding a critical nitrogen loading limit and maintaining or improving coastal water quality were interpreted as the "no net" nitrogen load policy. This means that development in a watershed to a nutrient-overloaded system cannot add any more nitrogen to the watershed or that the amount of nitrogen added by the project must be offset by an equivalent reduction.

The "no net" policy may be achieved by (1) providing wastewater treatment for the development or redevelopment and additional treatment capacity for nearby land uses; (2) installation of alternative denitrifying technologies for existing septic systems in the same Marine Water Recharge Area; and/or, (3) an equivalent monetary contribution of $1,550 per kilogram per year of nitrogen towards a municipal or watershed effort that achieves the intent of the "no net" load policy. The implementation of the policy was fairly successful and accepted by the towns and the regulated community. It resulted in increased levels of wastewater treatment from proposed package plants, the construction of package plants with excess capacity to hook in neighboring areas, and hundreds of thousands of dollars in mitigation funds for towns to pursue mitigation and/or CWMP development. Most importantly, it resulted in an acceptance that coastal eutrophication is an important matter for Cape Cod and that better treatment of wastewater is required.

The 2009 Regional Policy Plan changed the "no net" policy to reflect the newly adopted TMDLs by MassDEP and US EPA as the critical nitrogen loading limit. The performance standard interprets the adopted TMDL as a "fair share." The fair share is the TMDL equivalent load on a per-acre rate using the watershed and sub-watershed area. Fair-share nitrogen loads are calculated as the threshold controllable nitrogen load necessary to achieve TMDL compliance in the applicable surface water body, as indicated by the Massachusetts Estuaries Project, apportioned to the project in proportion to the size of the project area relative to the area contributing to applicable surface water body.

DRI project nitrogen loading calculations are reviewed to evaluate how a proponent could best meet the intent of the fair share. The Commission has developed a methodology to assist in calculating a project's nitrogen load and to compare its respective mitigation amount under the fair share.

The Commission's regulatory review of a CWMP is presently guided by the planning guidance and minimum performance standards of the Regional Policy Plan. The pertinent technical sections of the RPP include water resources, open space, natural resources, planning and historic preservation. Some of the requirements are similar to MassDEP requirements, but some are quite different. The pertinent standards from the RPP water resources section are available in Appendix 3B.

JOINT REVIEW PROCESS

As mentioned above, municipalities are typically required to file an EIR with the MEPA for the development of CWMPs. The Cape Cod Commission Act § 12(i) requires that the Commission shall review as a DRI any proposed development project for which the Massachusetts Secretary of Energy and Environmental Affairs (Secretary) requires the preparation of an Environmental Impact Report. As a result, at the conclusion of the MEPA process, the Commission conducts a regulatory review, and issues a written approval decision containing findings and conditions for all CWMPs proposed by Cape Cod towns.

A November 1991 Memorandum of Understanding (MOU) between the Commission and MEPA states that the environmental review processes of the Commission and the MEPA Unit are, in some instances, overlapping and that the environmental review procedures are similar. As

such, the MOU was executed given the extensive overlap of the statutory responsibilities of the Commission and the Secretary with respect to development on Cape Cod, in order to establish a coordinated review process for development projects that are subject to both Commission and MEPA review. The MOU establishes a coordinated voluntary Joint Review Process (JRP) for projects that are subject to MEPA and deemed to be DRIs pursuant to the Cape Cod Commission Act. The seventeen-step process is outlined as an attachment to the MOU. See Appendix 3C for the MOU.

DISTRICTS OF CRITICAL PLANNING CONCERN

The Cape Cod Commission Act provides for the designation of certain areas of critical value to Barnstable County as Districts of Critical Planning Concern (DCPCs).

A DCPC is a planning tool that allows for the adoption of special rules and regulations to protect, preserve, or promote an area, depending on the purpose of the DCPC. Certain local boards and commissions may nominate land within their own municipal boundaries, as well as land in a contiguous town (for example, a town could nominate land in a shared watershed to a nitrogen-sensitive embayment that lies within a neighboring town), as a DCPC. DCPCs may also be nominated by the Cape Cod Commission, the Board of County Commissioners and the Barnstable County Assembly of Delegates. Upon nomination to the Commission, the DCPC is considered by the Commission, which may in turn recommend it to the Assembly of Delegates and County Commissioners for adoption by county ordinance. Ultimately, implementing regulations are adopted and locally enforced by the town(s) to carry out the purposes of the DCPC. With the district designation comes a 12-15 month moratorium on certain development; the development moratorium is limited to specific development proposals as deemed necessary to support the purposes of the nominated district.

In terms of wastewater management or nitrogen control, as one example, a DCPC could be used to specify growth expectations in watersheds that are shared between one or more towns. The DCPC is a very flexible land use planning tool that could have many applications for water quality and growth planning on the Cape.

DCPCs are discussed further in Chapter 7 and a full list of designated DCPCs is available in Appendix 7A.

Other Regulations - Municipal

BOARD OF HEALTH REGULATIONS

Municipalities have authority and responsibility over wastewater flows within their jurisdiction in several ways. Boards of Health have jurisdiction over on-site septic systems and are responsible for enforcing compliance with Title 5 on the local level. Title 5 is a state minimum code, although municipalities may impose stricter standards then those found in Title 5. Under Title 5, Board of health responsibilities include:

- issuing permits and licenses for septic systems, septic installers and sewage haulers;
- controlling lot sizes and setbacks for purposes of siting septic system components;
- conducting inspections of septic systems;
- permitting the use of alternative systems, including denitrifying septic systems; and,
- mandating monitoring of alternative systems where applicable.

Boards of Health are responsible for defining what constitutes a bedroom for the purposes of septic system design flow requirements.

Boards of Health may also promulgate regulations more strict than imposed by Title 5. For example, under Title 5 a leaching field must be located at least 50 feet from a coastal bank, coastal dune, coastal beach, salt marsh, or vegetated wetland bordering on any creek, river, stream, pond, or lake. All Cape towns have increased this setback to 100 feet. Boards of Health may also issue variances and exemptions from certain requirements of local regulations.

In towns with sewers, Boards of Health or Sewer Commissions also promulgate water and sewer regulations. Several Cape Cod towns have implemented nutrient management controls through board of health regulations or general bylaws. Boards of Health have also adopted interim regulations for protection of saltwater estuaries. Some towns have taken steps to address flow-related growth potential through sewer connection regulations. These regulations limit flow to what existed before sewering

or to a small increase. These regulations are "growth neutral" in terms of design flow but do not address non-flow related criteria such as siting and setbacks.

Sewer-connection regulations set limits on the amount of wastewater flow to ensure that the capacity of a planned treatment plant is not exceeded and that TMDLs are met at present and in the future.

CONSERVATION COMMISSION REGULATIONS

WETLANDS PROTECTION

Although the jurisdiction of a local conservation commission is restricted to the delineated wetlands resource area and the 100-foot designated buffer (200 feet if the resource area meets the regulatory definition of a riverfront; 100 feet if it meets the requirement for a certified vernal pool), communities may expand the Massachusetts Wetlands Protection Act "protected interests" to include additional conservation values deemed important to the community. Like with Title 5, the WPA is a minimum code and communities may adopt more stringent wetlands rules for their community. The Massachusetts Association of Conservation Commissioners recommends that communities expand protected interests to include:

- Water quality, including surface water bodies
- Erosion/sedimentation control
- Natural habitat, wildlife habitat, rare species habitat, and wildlife corridors
- Agriculture, aquaculture, and shellfisheries
- Storm damage prevention, including coastal storm flowage
- Prevention and control of pollution
- Recreation

By including these as protected interests, the Conservation Commission has the ability to comment and impose conditions on proposed projects that may threaten resources that are no longer protected due to the elimination of Title 5 criteria.

Conservation Commissions may expand their jurisdiction over proposed projects by changing their bylaws and regulations that concern resource areas and buffer zones. Many Cape towns have established "No Build" and "No Disturb" zones within the 100-foot buffer. In no-build zones, no structures can be placed but some pruning is allowed. In no-disturb zones, no alteration can be made, including disturbing vegetation. Conservation Commissions can also extend jurisdiction by expanding the buffer zone beyond 100 feet.

The Cape Cod Commission has a model bylaw that provides language to extend the buffer zone to 200 feet for riverfronts in concordance with the riverfront amendments to the Massachusetts Wetlands Protection Act. Other language also expands the buffer to 300 feet for coastal plain pond shores, 350 feet for vernal pools, and 300 feet for wetlands that are designated as estimated habitat for rare species by the Massachusetts Natural Heritage and Endangered Species Program and for areas within Areas of Critical Environmental Concern.

Conservation Commissions may have jurisdiction when a septic system is upgraded if the existing system is not located with adequate depth to groundwater or if the leach field is less than the distance required from a wetland resource. If an existing system is repaired or upgraded, the new system must meet the requirements of the 100-foot buffer to the extent possible.

A thorough review of zoning and growth management measures and controls is included in Chapter 7 of this plan update.

LOW-IMPACT DEVELOPMENT

Low-impact Development (LID) is a comprehensive, conservation-based approach to land use planning. LID maintains the pre-development hydrology of a site through the use of natural stormwater best management practices including bio-retention filters, vegetated swales, shared driveways, pervious concrete, green roofs, and other strategies that promote the infiltration, filtering, storage, and evaporation of water on location. To date, none of the Cape towns have implemented comprehensive town-wide LID bylaws. However, several towns have adopted measures to improve stormwater treatment. For example, in 2011 the town of Brewster adopted Chapter 115 (Illicit Discharges bylaw) governing discharges to municipal storm systems. The Town of Dennis adopted a stormwater management bylaw in 2009.

NUTRIENTS FROM FERTILIZERS

Fertilizers are included in the nitrogen loading assessment prepared for each watershed by the MEP. With respect to controllable nitrogen loads, the percentage of unattenuated fertilizer load present in the coastal watersheds of Cape Cod ranges from 2% to 20% with an average of 9%.

MUNICIPAL FERTILIZER MANAGEMENT REGULATIONS

The Massachusetts Department of Agricultural Resources released draft regulations in March 2014 pursuant to M.G.L. c. 128, §2(k) and §65(A), as amended by St. 2012, c. 262. 330 CMR 31.00: Plant Nutrient Application Requirements for Agricultural Land and Land Not Used for Agricultural Purposes seeks to establish limitations on the application of plant nutrients to lawns and non-agricultural turf to prevent pollutants from entering surface and groundwater resources. In addition, the regulations ensure that nutrients are applied to agricultural land in a way that provides for plant growth while minimizing the impacts on water resources. Specific limits are proposed for the application of phosphorus: the application of nitrogen is required to be consistent with the University of Massachusetts Extension guidelines for nutrient best management practices for turf.

Barnstable County, through the regulatory authority of the Cape Cod Commission, designated Cape Cod as a Fertilizer Management District of Critical Planning and Concern, allowing municipalities on Cape Cod to further regulate the use of fertilizer. The Cape Cod Commission developed model regulations for use by the municipalities, which incorporate Turf Management Best Management Practices from the University of Massachusetts Extension, and provide specific nitrogen-related limits. For further information see Chapter 7.

Regulating the Solution: Permitting the Watershed

Changes in statute, regulation and practice will be necessary to provide the tools needed to cost effectively solve the water quality problems identified in this plan. The watershed permit is the central feature of the revised regulatory approach.

WATERSHED PERMITTING

The most important factors in defining the successful achievement of TMDL compliance lie with both the designation of the most effective Waste Management Agencies and redefining the watershed permitting process so that (1) the parties designated are those that can do the job; and (2) the process by which this task is achieved is direct and result-oriented.

The Watershed Permit

In reviewing the permitting process as it currently exists, it becomes clear that the jurisdiction of the solution lies within watershed management. Development of a watershed permit that would be obtained through MassDEP plays a central role in achieving compliance with the TMDL on a watershed-by-watershed basis.

Why is a watershed permit approach needed?

The current regulatory approach may not be conducive for the kinds of local plans expected based on recommendations from the Section 208 Plan Update. Non-traditional mitigation strategies may require a different regulatory approach to ensure that watershed-based nitrogen loading targets are met. Compliance points may differ from traditional end-of-pipe effluent limits. Determinations will need to be made on specific permit goals or limits that apply to the range of alternatives that may be considered as wastewater solutions.

How will the watershed permit work?

MassDEP is still evaluating the details of how a watershed permit will be drafted and implemented, as well as what regulatory and statutory changes could help make a transition to a watershed focus. The following will be considered in the development of this permit process:

- Groundwater discharge permit regulations, which are contained at 314 CMR 5.00, are broad enough to incorporate a watershed approach.

- Permits will be issued for one municipality or multiple municipalities in order to facilitate a focus on watersheds instead of decisions that are driven by town boundaries.
- Consideration of the formation of watershed districts and how to permit them will have to be addressed.
- Water quality targets established through the Massachusetts Estuaries Project, state water quality standards, and applicable total maximum daily loads (TMDLs) will be the foundation of the permit.
- Watershed permits will incorporate an appropriate strategy designed to achieve water quality targets based on the consideration of a variety of treatment approaches.
- Monitoring requirements will be incorporated into the permit and will be tailored to the treatment approaches being proposed to ensure that alternatives are resulting in the required nitrogen reduction or remediation.
- Adaptive management will be incorporated into the watershed plans and permits so that MassDEP can allow communities to try various approaches and determine their effectiveness, accurately monitor and assess their performance, and make any necessary changes to the overall approach needed to achieve the ultimate goal—achieving water quality targets in a timely manner.

What are the components to the watershed permit?

Under the watershed permit approach, the nitrogen load is allocated on a watershed by watershed basis. Approaches to allocating responsibility for nitrogen remediation are discussed in greater detail in Chapter 8, as is the requirement for designation of waste management agencies under Section 208 of the Clean Water Act.

The watershed permit will allocate a portion of the load reduction to each management technique being used in each watershed. The permit will establish standards and expectations for performance, define compliance and will establish the protocol for incremental steps for additional management if the initial measures fail to achieve compliance with the water quality standards. By authorizing and including alternative approaches into a permit, the watershed permit would unlock the savings that can come from properly sited and scaled alternative measures where no such permitting mechanism currently exists.

The permit would also implement a Nitrogen Credit Exchange Program that would be created by the Massachusetts Legislature. It would also reference the Nitrogen Credit Advisory Board which would be created by the Legislature to administer the exchange program. If a permittee cannot meet its specified limit, it must purchase equivalent nitrogen credits. Permittees generate credits when they produce less than their specified annual discharge load.

The general permit would establish the framework for WMAs seeking to offset proposed expansion or new construction by allowing the option of purchasing nutrient reductions generated by nonpoint source BMPs.

It is recommended that MassDEP issue guidance regarding watershed permitting.

Recommendation R3.2:
MassDEP should issue guidance regarding watershed permitting.

FEASIBILITY OF PERMITTING

In pursuing a watershed approach that encompasses the use of non-traditional technologies along with sewering in discreet areas, one issue that must be addressed is the current permitting process. In reviewing the current process it is clear that implementing the comprehensive process proposed in this plan utilizing the current permitting paths is, at its best, a daunting task, and at its worst, next to impossible (see **Figure 3-2**).

The existing permitting for both sewering and the non-traditional technologies as outlined above may require the following permits:

- Municipal Separate Storm Sewer Systems (known as “MS4”) from the Environmental Protection Agency (EPA)
- Groundwater discharge permits from DEP

Existing Permitting for Non-Traditional Technologies

Potential Permits by Technology

Figure 3-2

- Title 5 permits from each town's Board of Health in accordance with 310 CMR 15.00, Surface Water Discharges
- National Pollutant Discharge Elimination System (NPDES) permit from EPA
- An ACOE (Army Corps of Engineers) Section 401 Water Quality Certification that the activity complies with all applicable water quality standards, limitations and restrictions (as a precursor to all federal permits)
- MEPA (Massachusetts Environmental Policy Act) review if it meets the thresholds for review
- Each town Conservation Commission in accordance with the Wetlands Protection Act
- Water Management Act permit from DEP to withdraw over 100,000 gallons/day annually
- DEP and Board of Health approval for use of Innovative and Alternative Technology Systems
- Permits from MassDOT
- Permits from MA Historical Commission
- Approval from the MA Natural Heritage and Endangered Species Program
- Approval form the US Fish & Wildlife Service/ MA Division of Marine Fisheries

A more streamlined process will encourage better planning, enable better intermunicipal cooperation and provide enhanced ability for this plan to be successfully implemented. It is recommended that the watershed permit incorporate and streamline the multitude of permits required to implement a watershed plan.

TITLE 5 DESIGNATION OF NITROGEN SENSITIVE AREAS

MassDEP may identify certain areas as particularly sensitive to pollution from on-site wastewater systems and therefore require the imposition of loading restrictions. These Nitrogen Sensitive Areas (NSAs) include:

- Interim Wellhead Protection Areas and department-approved Zone IIs of public water supplies
- Areas with private wells
- Nitrogen-sensitive embayments or other areas which are designated as nitrogen sensitive under Title 5 based on appropriate scientific evidence

The design flow for wastewater is restricted to 440 gallons per day per acre (gpd/acre) in NSAs and higher levels of nitrogen removal are required. There are exceptions for aggregate flows and systems with enhanced nitrogen removal (typically referred to as Innovative/Alternative or I/A systems). I/A systems are regulated by the state at 310 CMR 15.000. A summary of the DEP approved Innovative/ Alternative systems is located at http://www.mass.gov/eea/agencies/massdep/water/wastewater/summary-of-innovative-alternative-technologies-approved.html. See 310 CMR 15.216 (aggregate flows) and 310 CMR 15.217 (enhanced nitrogen removal) for additional information.

The nitrogen-loading restrictions in NSAs apply to new construction only and do not affect existing Title 5 systems unless they are deemed to have failed or are required to be upgraded at the time of property transfer. Those systems are regulated through the inspection process and the definition of "failing" systems in 310 CMR 15.303 and 15.304. Title 5 has special requirements for repairing failed systems and for the construction of new systems in NSAs.

On Cape Cod, MassDEP has not designated watersheds to embayments that exceed their critical load as "nitrogen sensitive" because the designation would trigger the requirement for new development within the designated area to construct I/A systems. I/A systems are more costly than standard Title 5 systems, and the scenario development work conducted as part of the Section 208 Plan Update demonstrates that even 100% use of I/A systems in many watersheds will not achieve the nutrient reduction levels necessary to meet TMDLs.

MassDEP should consider designating as Nitrogen Sensitive Areas watersheds contributing to waterbodies impaired by nitrogen that are subject to a 208 Plan, whose development primarily relies on on-site septic systems and/or where the water body is listed on the 303(d) list due to nitrogen overloading and modify available remedial actions to allow for appropriate time for waste management agencies to plan. In addition, MassDEP should consider eliminating or amending the regulatory language establishing the presumption that Title 5 systems meet the state water quality standards in situations where it has been established that septic systems contribute to non-attainment.

Recommendation R3.3:
MassDEP should consider designating as Nitrogen Sensitive Areas watersheds contributing to waterbodies impaired by nitrogen that are subject to a 208 Plan, whose development primarily relies on on-site septic systems and/or where the water body is listed on the 303(d) list due to nitrogen overloading and modify available remedial actions to allow for appropriate time for waste management agencies to plan.

Recommendation R3.4:
MassDEP should consider eliminating or amending the regulatory language establishing the presumption that Title 5 systems meet the state water quality standards in situations where it has been established that septic systems contribute to non-attainment.

MODIFIED DEVELOPMENT OF REGIONAL IMPACT REVIEW

The Commission has historically reviewed CWMPs as DRIs pursuant to the Cape Cod Commission Act. In accordance with the Act, in order to approve a DRI, the Commission must find that a proposed project is consistent with any Commission-certified Local Comprehensive Plan (LCP); municipal development bylaws; any District of Critical Planning Concern Implementing Regulations; the Regional Policy Plan; and the probable benefit from a proposed project must be greater than the probable detriment.

The Regional Policy Plan contains over 200 minimum performance standards and best development practices in 12 different issue areas – including land use, economic development, water resources, coastal resources, wetlands, wildlife and plant habitat, open space and recreation, transportation, waste management, energy, affordable housing and heritage preservation/community character. Currently, these MPSs and Best Development Practices (BDPs) are applied during DRI review not only to site-specific individual developments, such as supermarkets and commercial businesses, but also to larger systemic phased projects, such as CWMPs.

The Section 208 Plan Update recognizes the need to modify the existing regulations in order to accommodate the unique nature of wastewater management planning and recommends consideration of alterations to Commission regulations.

The Commission should amend its regulations accommodating for the unique nature of capital wastewater management planning.

Recommendation R3.5: The Cape Cod Commission shall amend its regulations accommodating for the unique nature of capital wastewater management planning.

SPECIAL REVIEW PROCESS

The voluntary Cape Cod Commission/MEPA Joint Review Processed discussed above applies to comprehensive capital planning projects as well as individual parcel developments. CWMPs typically require MEPA review and Commission DRI review and Cape Cod towns have historically elected to participate in the JRP.

Additionally, the Secretary may establish a Special Review Procedure (SRP) for a project that may provide for coordination and consolidation of MEPA review with other environmental or development review and permitting processes (310 CMR 11). An example of an established SRP within Barnstable County is the Herring River Restoration Project in Wellfleet and Truro.

As an alternative to the existing JRP, a Special Review Procedure for Projects designed pursuant to the Section 208 Plan Update should be developed. The SRP should provide a framework for review and implementation of regional wastewater projects and provide flexibility and opportunities for streamlining. Projects could include CWMPs that address nutrient remediation in all watersheds

within a municipality or group of municipalities; Targeted Watershed Management Plans (TWMPs) that address nutrient remediation within a single watershed or a grouping of watersheds, wholly contained within one municipality, or shared by multiple municipalities; and Nutrient Remediation Projects that are individual water quality restoration projects addressing portions of watersheds or municipalities.

A Section 208 Plan Update SRP could contain the following elements:

- **CAPE COD COMMISSION SECTION 208 CONSULTATION:** Municipalities are encouraged to consult with the Commission to ensure coordination between active wastewater planning efforts and the Section 208 Plan Update and to establish consistency between proposed municipal plans and the Section 208 Plan Update with respect to the evaluation of wastewater needs, wastewater management alternatives, and alternatives analyses. Consultation also includes use of Commission decision support tools, such as WatershedMVP, with Commission staff assistance. The Commission would assign a Watershed Team to the specific planning efforts to assist with the decision support tools, permitting of technologies, and financing.
- **WATERSHED ASSOCIATIONS ESTABLISHED:** For projects addressing watersheds shared by more than one town, Watershed Associations could be established. Possible members could include elected and appointed municipal representatives, members of existing water quality advisory committees, representatives from Joint Base Cape Cod or the Cape Cod National Seashore, as appropriate, an expert on traditional wastewater approaches, representatives from the business, real estate and environmental sectors, a Commission representative, and an alternative technology representative. Under current regulations, when establishing a SRP, the Secretary ordinarily establishes a Citizens Advisory Committee (CAC) to assist in reviewing the project. Existing municipal CACs or water quality advisory committees, or a newly formed Watershed Association could be designated as the CAC.
- **WATERSHED MANAGEMENT PLAN DEVELOPED:** Watershed Management Plans should address all water quality planning including remediation of nitrogen, phosphorus, contaminants of emerging concern (CECs), etc. Individual projects identified as CWMPs, TWMPs and other Nutrient Remediation Projects could be eligible for the Section 208 Plan Update SRP. The Project plans should be submitted to MEPA and the Commission simultaneously for expedited review by both entities.
- **PUBLIC HEARING PROCESS:** The citizen engagement process should be expansive and educational and should allow for all public, local, state, regional and federal comment on proposed Projects.
- **FINAL EIR/COMMISSION DRI:** In order to streamline review, a simplified process of submitting one review document that can suffice as a Final EIR and Commission DRI application should be implemented. Upon approval, this document would lead to the Secretary's issuance of a Certificate of Adequacy for the FEIR and the Commission's DRI approval decision.

A recommendation of the Section 208 Plan Update is for the Commission to work with MassDEP and the Secretary of Energy and Environmental Affairs on a Special Review Procedure for Projects designed pursuant to the Section 208 Plan Update, to execute a Memorandum of Understanding between the Cape Cod Commission and the Secretary of Environmental Affairs, and to identify and implement other potential regulatory changes.

Recommendation R3.6: The Cape Cod Commission and MEPA should work together to develop an effective and streamlined process for reviewing projects designed pursuant to the Section 208 Plan Update that are reviewed jointly by both agencies.

SECTION 208 PLAN UPDATE CONSISTENCY REVIEW

A recommendation of this plan is the requirement that all nutrient management planning in the region be subject to review for consistency with the Section 208 Plan Update.

Recommendation R3.7: All nutrient management planning in the region shall be subject to review for consistency with the Section 208 Plan Update.

As outlined below, the consistency review will include, but is not limited to, a review of the planning approach used to ensure consistency with a proposed hybrid watershed planning approach; review and acceptance of a nutrient growth management plan; and a consistency review of the applicable Minimum Performance Standards and Best Management Practices for siting technologies. Specific guidance on the Section 208 Plan Update Consistency Review shall be issued within 90 days of its approval.

Recommendation R3.8: Specific guidance on the Section 208 Plan Update Consistency Review shall be issued by the Cape Cod Commission within 90 days of the 208 Plan Update approval.

Hybrid Watershed Planning Approach

It is recommended that for most watersheds, the most efficient and effective combination of watershed management strategies should include a planning process that integrates prevention, collection, and non-collection strategies. See Chapter 5 for a detailed discussion of the hybrid watershed planning approach.

Review and Acceptance of Nutrient Growth Management Plan

Growth management measures and strategies are an important component in managing nutrient impacts to coastal embayments. As part of the Section 208 Plan Update, the Commission recommends the establishment of a Nutrient Growth Management Plan. A commitment to review and accept or adopt a Nutrient Growth Management Plan shall be a requirement for any watershed plan seeking to realize the benefits related to consistency, and shall be a component of the Section 208 Plan Update Consistency Review. In addition, it is recommended that local plans segregate and present costs to manage nutrient removal from existing development and costs to manage nutrient removal from anticipated new development.

Minimum Performance Standards and Best Management Practices

As part of the Section 208 Plan Update, the Commission recommends MPSs and BMPs for siting technologies should be developed. Compliance with these MPSs and BMPs shall be requirements for any watershed plan seeking to realize certain benefits related to consistency. The MPSs and BMPs shall draw upon updated information in the Technologies Matrix for siting and monitoring technologies and approaches to nutrient management and shall be updated on a regular basis. They will address specific requirements from Section 208 of the Clean Water Act with regard to site selection impacts on water resources and other natural resources, including, but not limited to, impacts from construction and the location of disposal, and their effects on freshwater, saltwater and drinking water resources. Consistency with the MPSs and BMPs shall be a component of the Section 208 Plan Update Consistency Review.

Preserving Capacity for Towns in Shared Watersheds

Where centralized technologies are employed, localities should preserve capacity for treatment and/or disposal by towns in shared watersheds where feasible. Shared systems in higher density areas reduce costs for everyone by bringing more customers online to share costs.

Conducting a Fiscal Analysis of Costs to Taxpayers when Regional Solutions are not Adopted

In the event a municipality determines that it will not pursue available opportunities to design, construct and operate shared infrastructure, they shall conduct and present a fiscal analysis of potential additional costs associated with constructing infrastructure limited to town boundaries.

04 SOLUTIONS

Nutrient Mitigation Technologies & Policies

Cape communities have been aware of decreasing water quality in estuaries and coastal waters for over a decade – but there is little consensus on how to address the problem. Comprehensive wastewater planning at the municipal level is often impeded by concerns about scope and cost, which can lead to failed town meeting votes. The need to identify management options for nutrients beyond traditional collection and centralized treatment approaches became evident. This chapter presents the results of an extensive search for and vetting of alternative approaches for nutrient management on Cape Cod.

SOLUTIONS

Chapter 4: Nutrient Mitigation Technologies & Policies

Tools for Nutrient Management in Coastal Waters

Cape Codders are closely connected to the water. Whether salt or fresh, water defines Cape Cod and each person's experience with the environment. In the search for solutions to water quality problems, alternative technologies, tools, policies and approaches that may restore water quality in affected water bodies more quickly and cost effectively than traditional methods have been identified. Techniques that may be applied directly within the water body have raised questions about their potential effectiveness, reliability and speed to results.

Water Quality Technologies Matrix

Figure 4.1 (Facing Page)

The technologies and approaches included in the Technologies Matrix address nutrients by means of reduction, remediation, and restoration and are implementable in scales ranging from on-site, to neighborhood, watershed, and Cape-wide.

The Section 208 planning process has provided the opportunity to take an in-depth look at a broad range of techniques for managing nutrients. This chapter examines 10 categories and a total of 67 nutrient reduction, remediation and restoration technologies and approaches. This work is embodied in the Water Quality Technologies Matrix (Technologies Matrix) and then simplified based on the point of intervention, the scale of the technology or approach (site, neighborhood, or watershed) and whether it requires a collection system to remove waste from the property for disposal in another location. The Technologies Matrix includes the breadth of traditional approaches, from on-site (Title 5) systems to centralized treatment facilities, and a diverse array of non-traditional or alternative approaches, ranging from coastal habitat restoration to source-reducing toilets (**Figure 4.1**). The Technologies Matrix is the result of nearly two years of research by Cape Cod Commission staff and consultants, review by a panel of experts, followed by vetting by state, federal, and other stakeholders. **Table 4-1** identifies the technologies and strategies that have been examined.

The Technologies Matrix is conceived as a living compendium of data on nutrient management technologies. The technologies in the Matrix have all shown some promise for being used for nitrogen management; however, many are yet untested on Cape Cod or have been deployed at scales smaller than might be necessary in a watershed plan. It became clear through the research, as well as in questions raised during the many discussions among planning staff, stakeholders, academia and government and private experts, that the Technologies Matrix needs continual refinement as new or more accurate information becomes available through research or from pilot projects on Cape Cod. The actions needed to implement water quality improvements across the Cape will contribute to the body of knowledge about non-traditional nutrient management technologies, allowing us to refine the list of best practices that have proven to be effective in solving water quality problems. It is recommended that the Cape Cod Commission develop a process for annual updates to the Technologies Matrix.

TECHNOLOGY GROUPING	TECHNOLOGY / STRATEGY
Green Infrastructure	Constructed Wetlands - Surface Flow
	Constructed Wetlands - Subsurface Flow
	Constructed Wetlands - Groundwater Treatment
	Hydroponic Treatment

	Thermal Drying
	Drying and Gasification

Technologies Included in the Water Quality Technologies Matrix

Table 4-1

Recommendation I4.1: The Cape Cod Commission shall develop a process for annual updates to the Technologies Matrix.

Among the actions needed to validate the efficacy of non-traditional approaches are the piloting of technologies in suitable locations, monitoring water quality and environmental parameters down gradient from a technology, analyzing technology performance and updating the Technologies Matrix as appropriate. Piloting, monitoring and analysis are discussed later in this chapter, along with corresponding recommendations for action. In addition, this plan recommends an annual symposium to present and review new research on these nutrient management techniques. The symposium will support the exchange of research on these tools and provide an opportunity to share experiences on the implementation of pilot projects. New findings may then be incorporated into the Technologies Matrix on a regular basis. A web-based interface will make the data on these technologies available to anyone.

Recommendation I4.2: The Cape Cod Commission shall seek opportunities to sponsor an annual symposium to present and review new research on nutrient management technologies and approaches that coincides with regular updates to the Technologies Matrix.

Catalog of Non-Traditional Technologies

In the pages that follow, summaries of the non-traditional technologies and approaches are presented in an at-a-glance format. This "catalog" of technologies provides a simple method of comparison. Among the features covered in this section are the benefits and performance challenges of a technology, its efficiency in addressing nitrogen, its resilience to sea level rise and whether it rose to the top as a technology for use in developing watershed scenarios on Cape Cod.

Each tool or practice has been categorized according to the scale and the situation in which it best performs. Technologies sorted as restoration are those that address nutrient rich water within an affected water body. Technologies categorized as remediation are those that treat nutrient rich water as it travels through the groundwater, before it reaches a water body. Technologies identified as reduction are those that reduce nitrogen before it enters the groundwater.

As discussed at many of the stakeholder meetings, the Section 208 Plan Update recognizes that while non-traditional technologies hold great promise in managing nutrients in groundwater and water bodies, traditional technologies will also play a significant role in wastewater management. Following the catalog of information presented below, the types and merits of traditional wastewater treatment are reviewed. Traditional wastewater approaches typically do not require piloting to establish performance; consequently, brief summaries of the types of technologies are presented in this chapter to familiarize the reader with the range of methods available.

Detailed performance information may not be available for all technologies at this time. However, a more detailed narrative of each of each technology can be found in Appendix 4A; the most detailed and extensive information can be found in the Technologies Matrix, available in Appendix 4B or on the web at: http://capecodcommission.org/matrix.

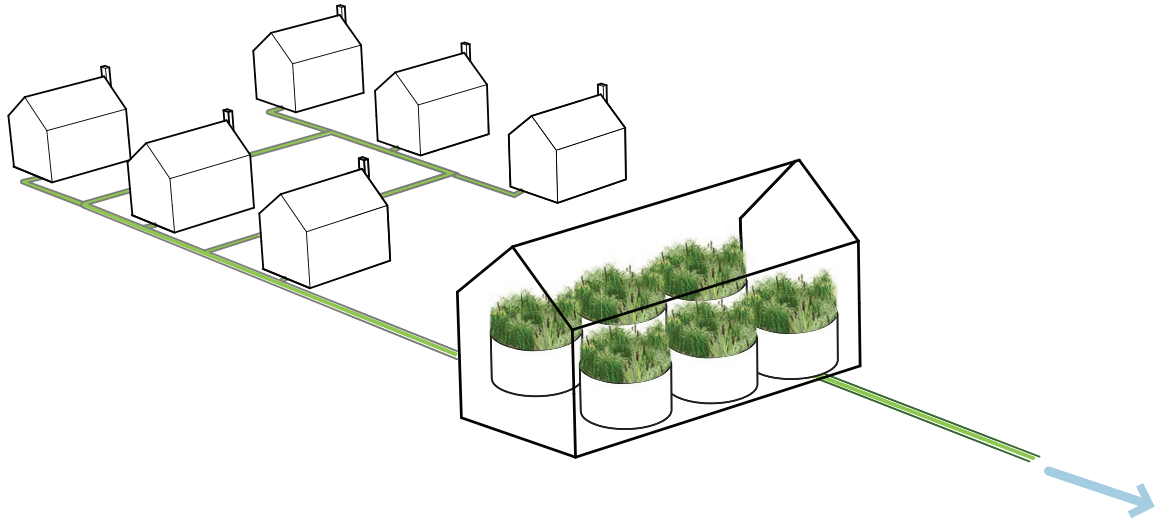

Figure 4-2

Hydroponic Treatment

SCALE: SITE/NEIGHBORHOOD/WATERSHED
APPROACH: REDUCTION

SCENARIO PLANNING: NOT SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Hydroponic treatment and Photo Bioreactors are natural systems that treat septic tank effluent or primarily treated wastewater. With Hydroponic Treatment, aeration and clarification chambers are combined with constructed wetlands to treat the influent. The wetlands are a series of chambers allowing for microbial communities to engage with and treat the wastewater. Plants are often suspended on racks with their roots systems doing the work. Solids removal is generally onsite, after which water is pumped through the gravel filled cells (similar to subsurface wetlands.) This process transfers more oxygen to the wastewater and completes the pollutant removal process. The wetland effluent can be discharged into a water body or used for open space irrigation after treatment. The wetland effluent can also be discharged into a leach field or similar system for discharge to the groundwater.This technology can also be used for wastewater treatment with primary, secondary, or advanced effluent generally for flows less than 500,00 gpd.

Hydroponic Treatment

SCALE: SITE/NEIGHBORHOOD/WATERSHED
APPROACH: REDUCTION

SCENARIO PLANNING: NOT SELECTED FOR USE
IDENTIFIED FOR PILOTING

SITING NEEDS

- Adjacent to housing and development

ECO-BENEFITS

- Promotes Green Space / Conservation / Recreation
- Improves Management of Flooding / Extreme Events

PERFORMANCE CHALLENGES

- Require high energy and maintenance costs as these systems are generally constructed in greenhouses
- Low phosphorus removal rates

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to more frequent inundation and increased exposure to saline water
- Mobilization of contamination as a result of failure of storage system
- Backflow of saline water into system causing overflows, increased degradation of materials and change in biological processes
- Destabilization of assets as a result of changes in groundwater levels or erosion

CLIMATE RESILIENCE: SOLUTIONS

- Locate infrastructure outside the flood hazard area that is anticipated for the life of the installation
- Select materials and coatings that are able to cope with an increasingly saline environment
- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets)
- Backflow valves on outlets
- Anchoring of buried assets

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Massachusetts Department of Environmental Protection

Fertilizer Management

N+P+K MGMT

SCALE: CAPE WIDE
APPROACH: REDUCTION

SCENARIO PLANNING: SELECTED FOR USE

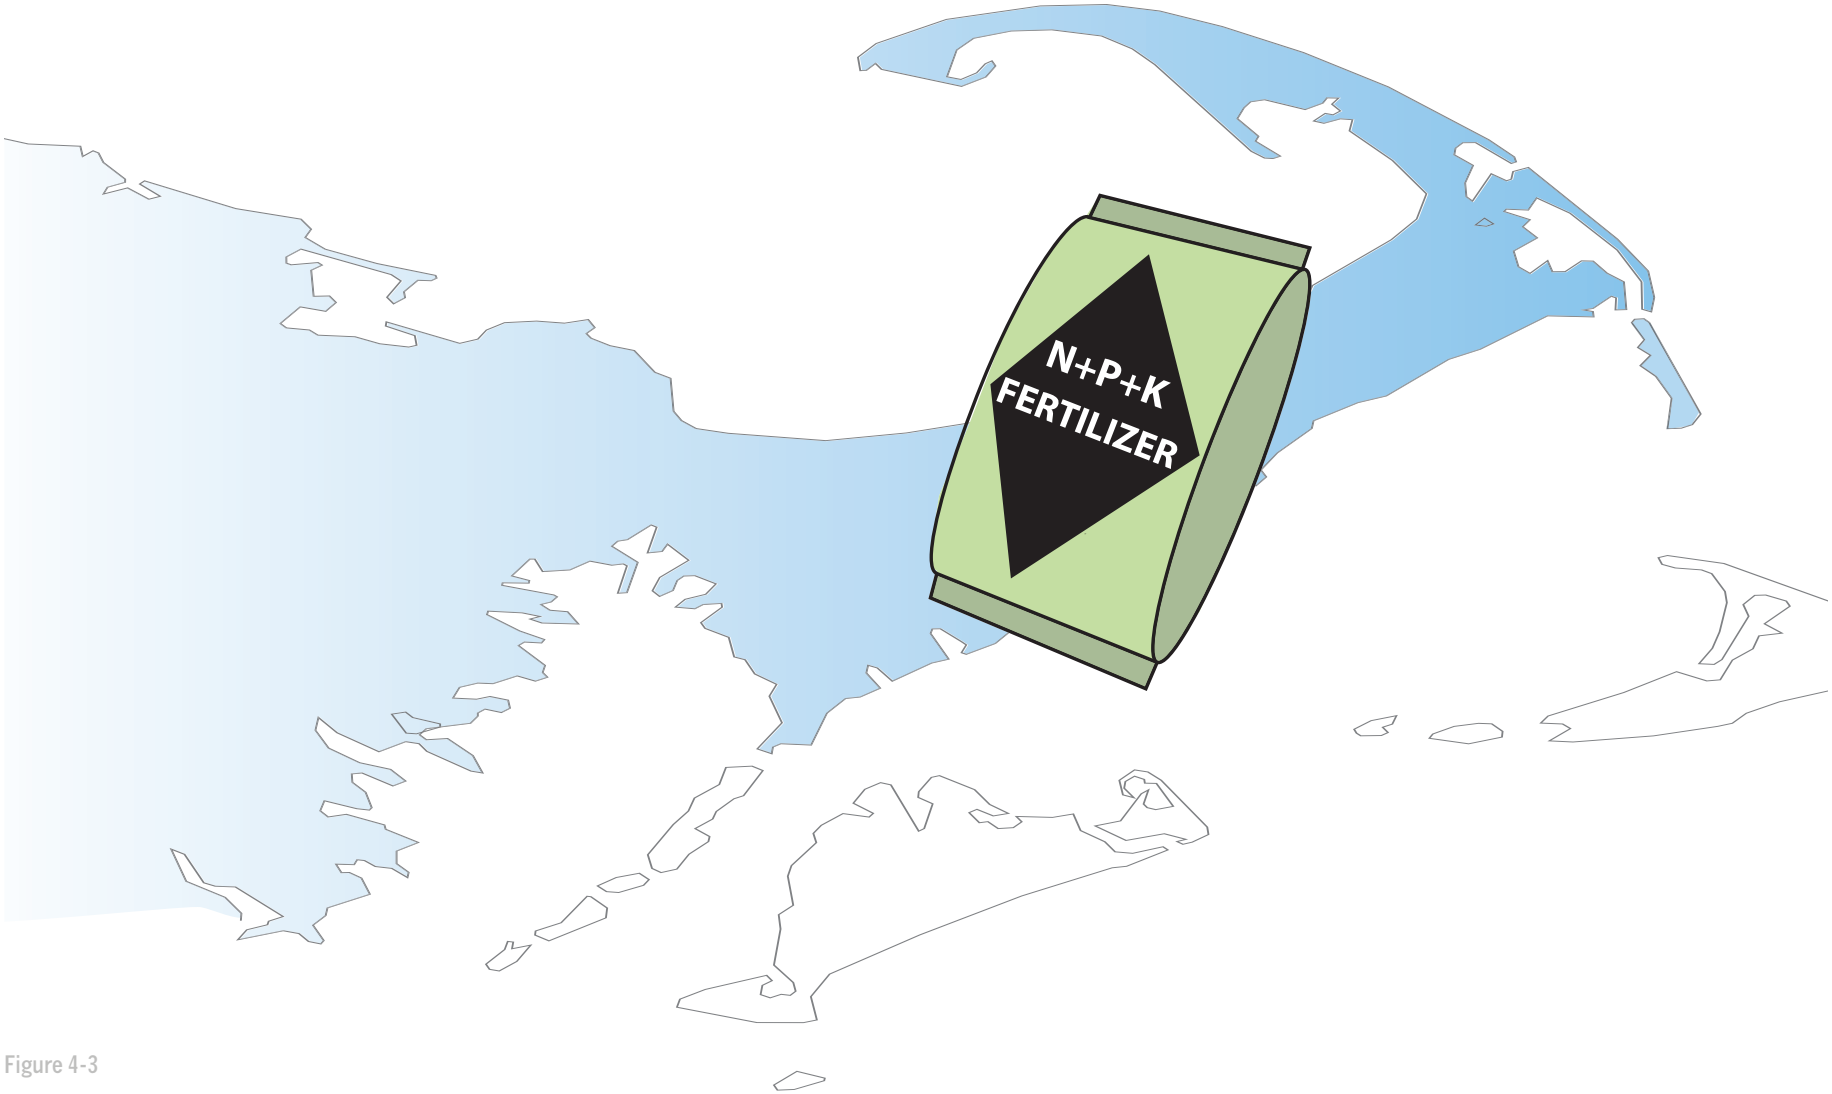

Figure 4-3

Fertilizer Management

SCALE: CAPE WIDE
APPROACH: REDUCTION

SCENARIO PLANNING: SELECTED FOR USE

N+P+K MGMT

DESCRIPTION

This approach relies on managing fertilizer application rates to lawns, golf courses, athletic facilities and cranberry bogs. Residential lawn loading rates could be reduced on existing developed parcels through an intensive public education/ outreach program. This could include a "Cape Cod Lawn" branding program, replacing some turf areas with native vegetation, establishing naturally-vegetated buffer strips on waterfront lots, and reducing application rates. Fertilizer loading rates for new development could be accomplished by reducing lot sizes (cluster development), by restricting lawn sizes and/or by incorporating more naturally-vegetated open space areas. Municipalities could directly reduce fertilizer applications on athletic fields and other properties. Golf courses can significantly reduce nitrogen loading rates by using slow-release fertilizers and reducing application rates in rough areas.Cranberry bog fertilizer exports from the bogs can be reduced using tail water recovery systems. Site-specific assessments are needed to estimate load reductions.

SITING NEEDS

- Fertilizer management does not have specific site requirements.

ECO-BENEFITS

- Enhances Habitat / Wildlife / Biodiversity

PERFORMANCE CHALLENGES

- Resulting nutrient removal rates are highly dependent on homeowner / landowner behavior and participation in the program
- Site-specific assessments are needed to estimate load reductions

CLIMATE RESILIENCE: RISKS

- Fertilizer management does not result in significant climate resiliency risks.

CLIMATE RESILIENCE: SOLUTIONS

- Climate resiliency solutions are not needed for Fertilizer Management.

Permitting

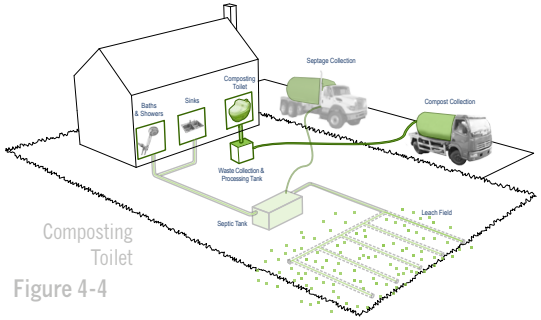
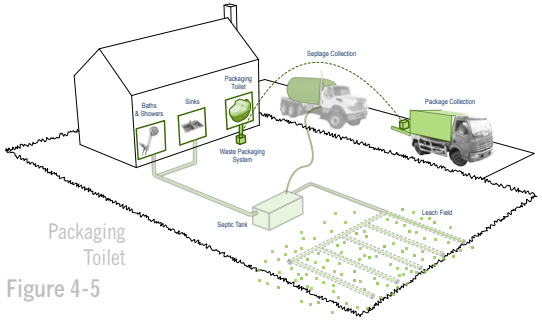
Waste Reduction Toilets

SCALE: SITE
APPROACH: REDUCTION

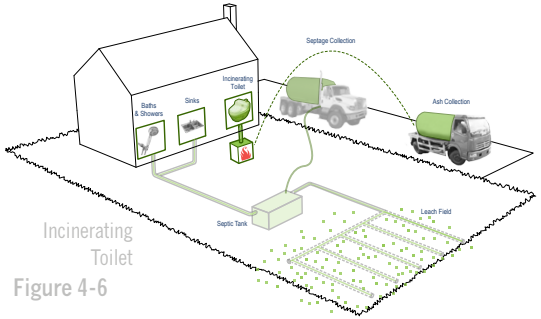
SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING



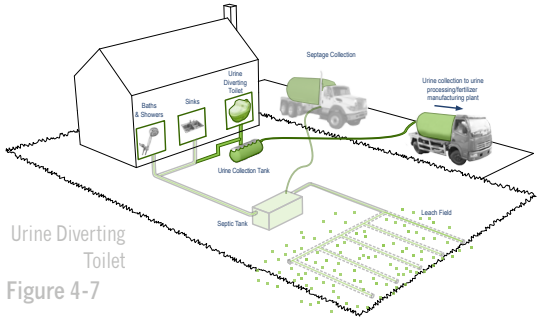
Composting Toilet
Figure 4-4



Packaging Toilet
Figure 4-5



Incinerating Toilet
Figure 4-6



Urine Diverting Toilet
Figure 4-7

DESCRIPTION

A waste reduction toilet is a system which separates human waste from shower, sink and other household water uses. These systems use no or minimal amounts of water. Waste reduction toilets require the installation of a separate toilet(s). Household water uses (i.e. sink and shower uses) continue to flow to the septic system.The four main categories of waste reducing toilets include: composting, incinerating, packaging and urine diverting. Composting toilets capture human waste in a container in the basement where it is decomposed and turned into compost. Incinerating toilets rely on electric power or natural or propane gas to incinerate human waste to sterile, clean ash. Packaging toilets encapsulate human waste in a durable material, stored beneath the toilet, for removal from the site when full. Urine diverting toilets divert urine to a holding tank where it is periodically collected by a servicing company; remaining human waste continues on to the septic system.

SITING NEEDS

- Requires a Title 5 System for ther gray water sources

ECO-BENEFITS

- Improves Energy Savings, Nutrient Recovery, Recycling

PERFORMANCE CHALLENGES

- Resulting nutrient removal rates are highly dependent on homeowner/landowner behavior and participation in the program
- Requires a significant number of citizens to participate to be effective

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to increased exposure to saline water
- Mobilization of contamination as a result of failure of storage system
- Backflow of saline water into system causing overflows, increased degradation of materials and change in biological processes
- Reduced effectiveness of biological processes as a result of more frequent inundation or exposure to saline water (surface or ground water)
- Temporary restricted access to infrastructure to remove waste materials and undertake maintenance. Longer term access restriction may lead to reduced performance or overflow

Waste Reduction Toilets

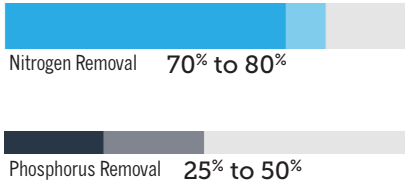
SCALE: SITE
APPROACH: REDUCTION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

CLIMATE RESILIENCE: SOLUTIONS

- Select materials and coatings that are able to cope with an increasingly saline environment
- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets)
- Backflow valves on system
- Anchoring of buried assets

Composting Toilet

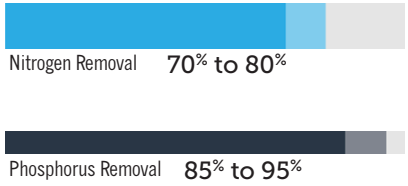


$266	$2,323
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)
20 years	1 to 10 years
Useful Life	Time to See Results

SPECIFIC PERFORMANCE CHALLENGES

- Requires ongoing maintenance to function correctly
- Requires independent citizens to change systems to be cost effective

Incinerating Toilet

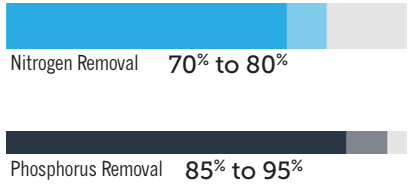


$328	$1,195
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)
20 years	1 to 10 years
Useful Life	Time to See Results

SPECIFIC PERFORMANCE CHALLENGES

- Incineration process demolishes any nutrients found in human waste - meaning it cannot be used for nourishing soil
- Saves water, but uses more energy
- Still requires septic tank and leaching field for grey water
- The proprietary nature of this technology will impose high fees for waste removal and maintenance

Packaging Toilet



$198	$720
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)

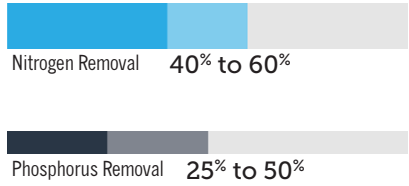
SPECIFIC PERFORMANCE CHALLENGES

- Still requires septic tank and leaching field for grey water
- The proprietary nature of this technology will impose high fees for waste removal and maintenance

Urine Diverting Toilet



$333	$2,912
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)
20 years	1 to 10 years
Useful Life	Time to See Results

SPECIFIC PERFORMANCE CHALLENGES

- Requires company infrastructure to pick up package
- Tight tank for urine storage required.

SPECIFIC POTENTIAL PERMITTING AUTHORITIES

- Municipality (Local plumbing inspector)
- Municipal Board of Health

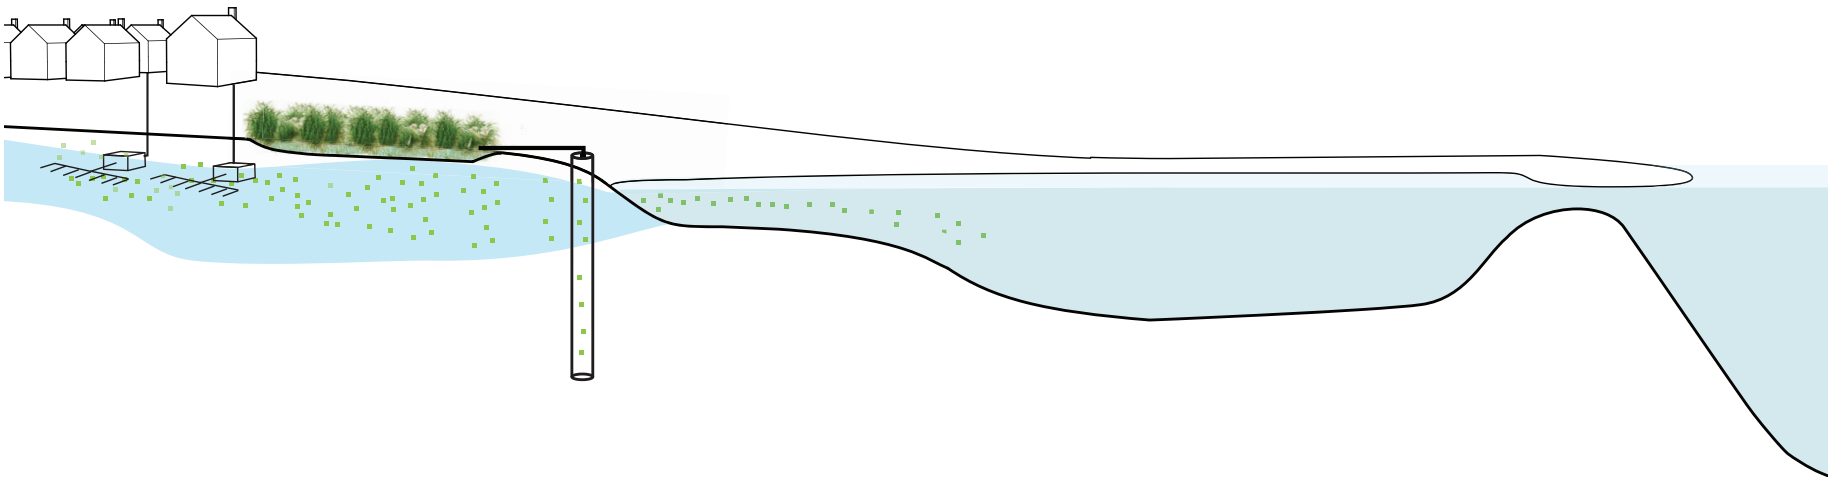


Figure 4-8

Constructed Wetlands Groundwater Treatment

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: REMEDIATION
SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

After collecting groundwater with higher nitrogen concentrations, groundwater is treated by pumping water slowly through subsurface gravel beds where it is filtered through plant root zones and soil media. Water flows 3" to 8" under the surface to prevent public exposure to wastewater and mosquito breeding. A combination of horizontal and vertical flow subsurface systems must be utilized to provide total nitrogen removal. These systems occasionally use additional treatment steps to remove nutrients from wastewater. The preferred disposal method is an infiltrator chamber system similar to a leach field but larger in size and designed for overflows. The reclaimed water is generally then discharged to the groundwater. The reclaimed water can also be discharged into a water body or used for open space irrigation after treatment. However, more strict permitting and water quality standards must be met if not discharging to groundwater.

Technology Performance

Nitrogen Removal 85% to 95%

Phosphorus Removal 50% to 90%

$340	$437
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)

Constructed Wetlands Groundwater Treatment

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE IDENTIFIED FOR PILOTING

SITING NEEDS

- Undeveloped land > 1 Acre
- Outside all wetlands resource areas
- Outside 100 year flood hazard zone
- Groundwater separation - GW depth > 4 feet
- Not within priority habitat areas
- Not within protected open space
- Benefit if site has clay based soils, has disturbed soils, parcel intersects with 50 to 100 foot Buffer zone, has municipal ownership
- No steep topography

ECO-BENEFITS

- Enhances Habitat / Wildlife / Biodiversity
- Promotes Green Space / Conservation / Recreation
- Improves Energy Savings / Nutrient Recovery / Recycling
- Improves Management of Flooding / Extreme Events

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Municipal Conservation Commission
- Massachusetts Department of Environmental Protection

PERFORMANCE CHALLENGES

- Higher maintenance in first few years
- May require carbon source initially
- Can become clogged over time
- Phosphorous removal may decline over time
- May require fencing and security measures
- May attract water fowl which could aggravate N issue
- In addition, on the Cape, these systems may need to be lined to prevent complete infiltration and allow time for N removal rather than just putting N into groundwater

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to more frequent inundation and increased exposure to saline water
- Mobilization of contamination as a result of failure of storage system
- Backflow of saline water into system causing overflows, increased degradation of materials and change in biological processes
- Destabilization of assets as a result of changes in groundwater levels or erosion
- Reduced effectiveness of biological processes as a result of more frequent inundation or exposure to saline water (surface or ground water)

CLIMATE RESILIENCE: SOLUTIONS

- Locate infrastructure outside the flood hazard area that is anticipated for the life of the installation
- Select materials and coatings that are able to cope with an increasingly saline environment
- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets and health of vegetation)
- Backflow valves on outlets
- Anchoring of buried assets
- Project design and species selection to ensure adequate performance in increasingly saline environments

Constructed Wetlands Surface Flow

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

After primary treatment in a septic tank or WWTF or secondary treatment at a WWTF, water is fed into a free water surface (FWS) constructed wetland. Free water constructed wetlands closely mimic the ecosystem of a natural wetland by utilizing water loving plants to filter wastewater through their root zone, a planted medium, and open water zones. FWS wetlands are systems where open water is exposed much like in a natural marsh. The reclaimed water is generally discharged into a leach field or similar system for discharge to the groundwater. The reclaimed water can also be discharged into a water body or used for open space irrigation after treatment. However, more strict permitting and water quality standards must be met if not discharging to groundwater. This technology can be used as an alternative to conventional polishing (i.e. mechanical and/or chemical) of secondary and advanced wastewater treatment.

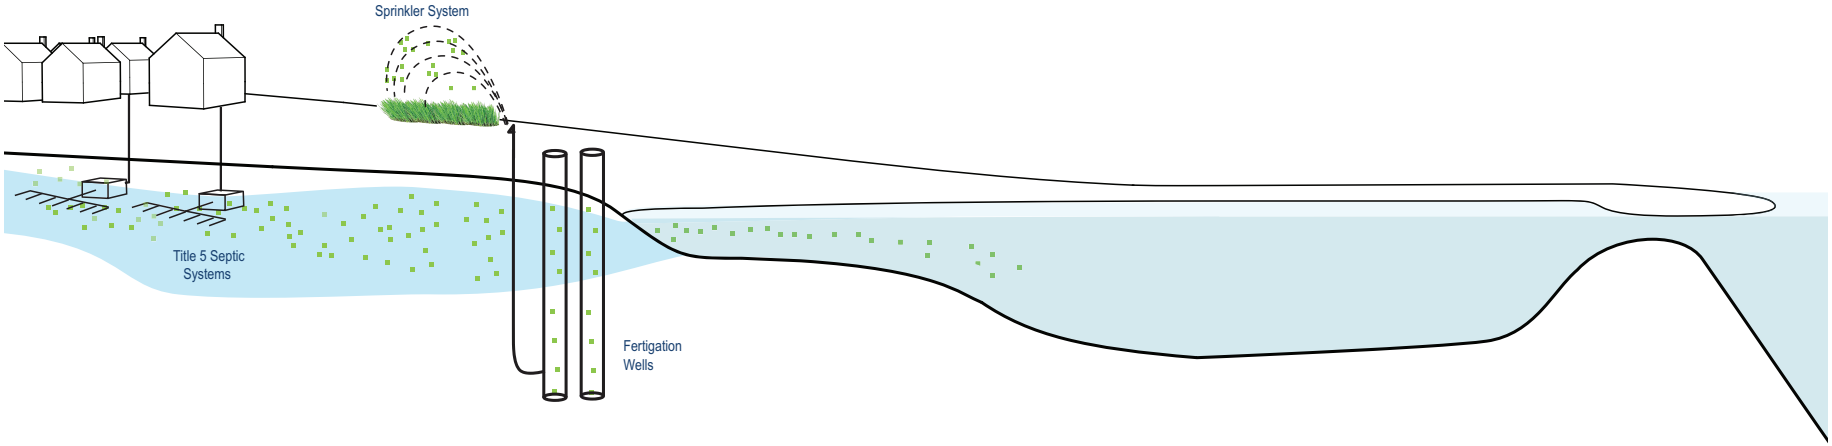

Figure 4-11

Fertigation Wells

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Fertigation consists of capturing nitrogen enriched groundwater via wells and using it to irrigate plants that use the nutrients. Fertigation wells can capture nutrient enriched groundwater and recycle it back to irrigate and fertilize turf grass areas, and to irrigate crops. Irrigated turf grass areas include golf courses, athletic fields and lawns, while irrigated crops typically include cranberry bogs. Fertigation can reduce nutrient loads to down gradient surface waters while reducing fertilizer costs to the irrigated areas.

Technology Performance

Nitrogen Removal 60% to 80%

Phosphorus Removal 60% to 80%

Fertigation Wells

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

SITING NEEDS

- Fertigation wells should be located down gradient of nutrient source areas such as wastewater treatment plant disposal fields and compact development
- They can also be positioned down gradient of high-density subdivisions where they might capture nutrients derived from both septic systems and residential lawns
- The specific locations, depths and diameters can be optimized using standard hydrogeologic principles

ECO-BENEFITS

- Promotes Green Space / Conservation / Recreation
- Improves Energy Savings / Nutrient Recovery / Recycling

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Turf: Massachusetts Department of Environmental Protection
- Cranberry Bogs: Massachusetts Department of Environmental Protection and Municipal Conservation Commission

PERFORMANCE CHALLENGES

- Seasonal technology potentially requiring several capture wells to capture entire nutrient plume
- Most effective in areas where groundwater contains a "plume" of high concentration of nutrients (i.e. down gradient of a WWTF discharge, etc.)
- Need an area to irrigate for nutrient uptake
- May require monitoring

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to more frequent inundation and increased exposure to saline water
- Inundation leading to saltwater intrusion into groundwater potentially affecting reuse of water (e.g. irrigation)
- Destabilization of assets as a result of changes in groundwater levels or erosion

CLIMATE RESILIENCE: SOLUTIONS

- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets)
- Select materials and coatings that are able to cope with an increasingly saline environment
- Backflow valves on outlets
- Anchoring of buried assets
- Locate technology outside flood hazard area anticipated for the life of the installation

IDENTIFIED FOR PILOTING

SITING NEEDS

- Undeveloped open land > 1 acre
- GW depth > 4 feet
- Permeable soils
- Outside all wetlands resource areas
- Outside 100 year flood hazard zone

ECO-BENEFITS

- Enhances Habitat / Wildlife / Biodiversity
- Promotes Green Space / Conservation / Recreation
- Improves Energy Savings / Nutrient Recovery / Recycling
- Improves Management of Flooding / Extreme Events

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Municipal Conservation Commission
- Massachusetts Department of Environmental Protection

PERFORMANCE CHALLENGES

- Will likely require meeting stringent and costly water reuse regulations including increased treatment and monitoring requirements
- Plants can only be irrigated during growing season (about 3 months)
- For tree systems, it takes several years before plants are mature enough to uptake the maximum number of gallons per day requiring the effluent be held in holding ponds until the irrigation season

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to more frequent inundation and increased exposure to saline water
- Mobilization of contamination as a result of failure of storage system
- Backflow of saline water into system causing overflows, increased degradation of materials and change in biological processes
- Destabilization of assets as a result of changes in groundwater levels or erosion
- Reduced effectiveness of biological processes as a result of more frequent inundation or exposure to saline water (surface or ground water)

CLIMATE RESILIENCE: SOLUTIONS

- Locate infrastructure outside the flood hazard area that is anticipated for the life of the installation
- Select materials and coatings that are able to cope with an increasingly saline environment
- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets and health of vegetation)

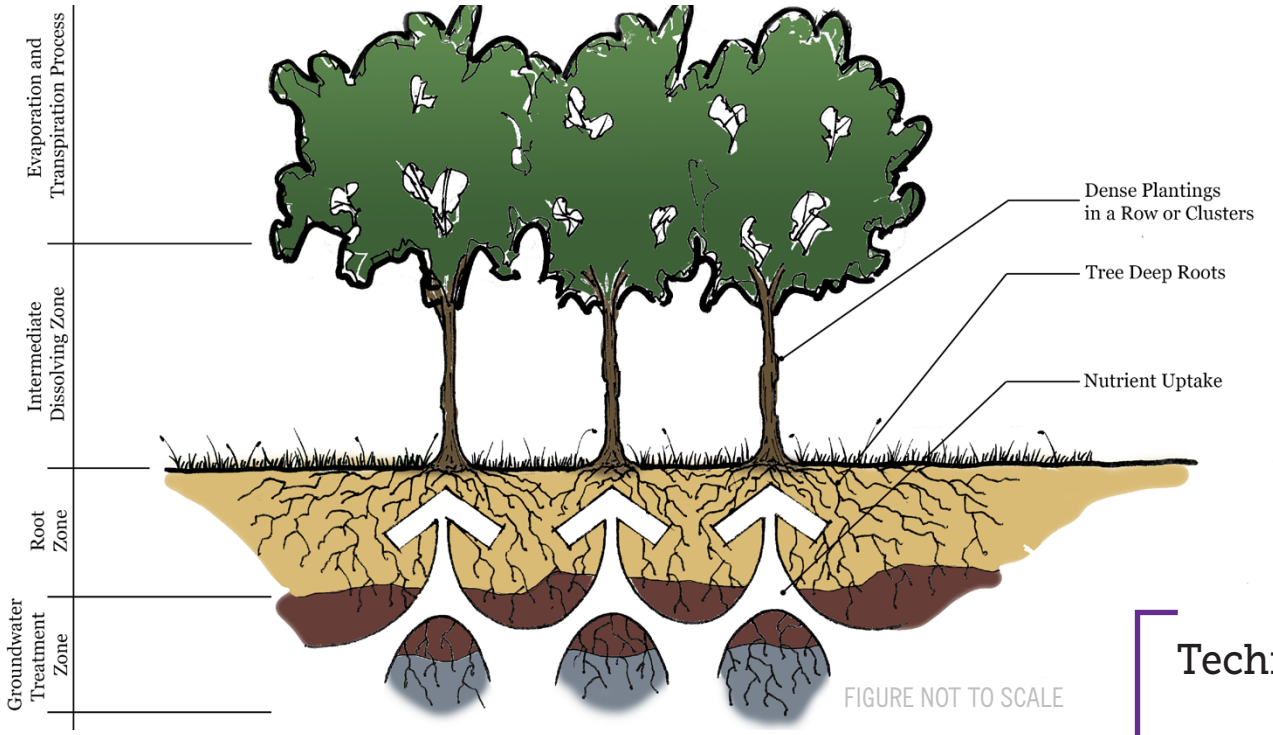

Figure 4-13

Phytoremediation

SCALE: SITE/NEIGHBORHOOD
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE IDENTIFIED FOR PILOTING

DESCRIPTION

Green plants with deep tap roots are planted as a buffer to intercept high nitrogen (nitrogen enriched) groundwater. The plants and microorganisms in their root zone reduce/use the nitrogen, removing it from the groundwater and watershed. Phytoremediation can be used to redirect a plume of nitrogen enriched groundwater or pull it up from deeper in the aquifer, allowing the plants to treat the plume.

Technology Performance

Nitrogen Removal 50% to 90%

Phosphorus Removal 20% to 60%

$228	$1,999
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)
20 years	1 to 10 years
Useful Life	Time to See Results

Phytoremediation

SCALE: SITE/NEIGHBORHOOD
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

SITING NEEDS

- Permeable soils
- Depth to groundwater <10 feet
- Not within priority habitat areas
- Not within protected open space
- Benefit if site is located within a Zone II, has disturbed soils, parcel intersects with 50 to 100 foot wetland buffers, has municipal ownership, necessary nitrogen removal in groundwater filtering through parcel is high

ECO-BENEFITS

- Enhances Habitat / Wildlife / Biodiversity
- Promotes Green Space / Conservation / Recreation
- Improves Energy Savings / Nutrient Recovery / Recycling
- Improves Management of Flooding / Extreme Events

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Licensed Site Professional/Massachusetts Department of Environmental Protection
- U.S. Environmental Protection Agency

PERFORMANCE CHALLENGES

- In year one after planting, no remediation occurs because trees have not reached the groundwater. As the trees get larger and pump more water, nitrogen removal rates increase and plateau
- Plants can only be irrigated during the growing season, requiring use of holding ponds in non-growing season.

CLIMATE RESILIENCE: RISKS

- Reduced effectiveness of biological processes as a result of more frequent inundation or exposure to saline water (surface or ground water)

CLIMATE RESILIENCE: SOLUTIONS

- Ensure frequent maintenance inspections to monitor condition and performance of technology (i.e. achieving nutrient removal targets and health of vegetation)
- Species selection to ensure adequate performance in increasingly saline environments
- Preserve areas / buffers to allow migration of salt marsh to higher elevations as MHW rises

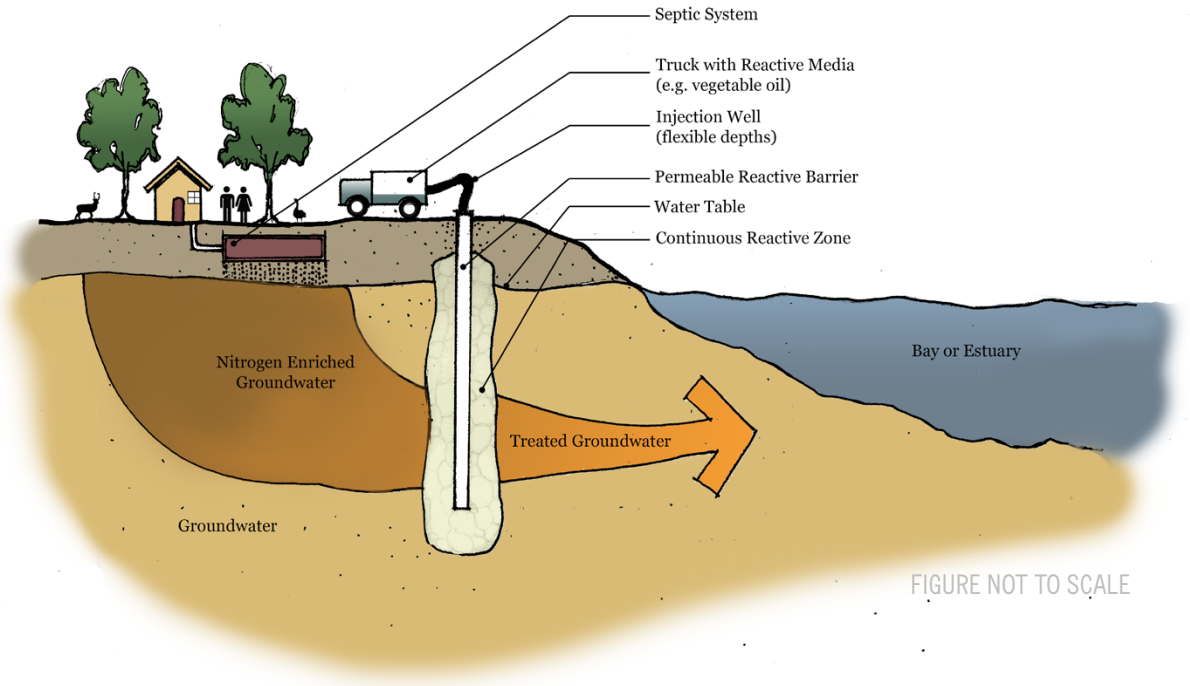

Figure 4-14

Permeable Reactive Barriers (PRBs) Injection Well Method

PRB

SCALE: SITE/NEIGHBORHOOD
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

A permeable reactive barrier (PRB) is an in-situ (installed within the aquifer) treatment zone designed to intercept nitrogen enriched groundwater. Through use of a carbon source, microbes in the groundwater uptake the nitrogen, denitrifying the groundwater. An injection Well PRB system typically uses a series of injection wells to introduce the carbon source (medium) into the groundwater.The injection wells can be installed to depth greater than the PRB trench method. The injection well PRB method can be used in combination with the PRB trenching method described previously. As groundwater flows through the medium, microbes naturally occurring in the groundwater consume the carbon source, as well as oxygen, developing an anaerobic environment. This process releases nitrogen gas to the atmosphere, reducing the groundwater nitrogen load before reaching the estuary.

Technology Performance

Nitrogen Removal 75% to 95%

Phosphorus Removal 50% to 95%

$279	$1,310
Removal Cost per kg N (avg life cycle)	Removal Cost per kg P (avg life cycle)

Permeable Reactive Barriers (PRBs) Injection Well Method

SCALE: SITE/NEIGHBORHOOD
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE IDENTIFIED FOR PILOTING

PRB

SITING NEEDS

- Suitable groundwater flow path (depth to intercept groundwater)
- Generally at least 20 feet of saturated aquifer thickness is desired
- In general, the injection well PRB can be installing areas with steeper topography than a trench PRB
- In general, the injection well PRB can be installing areas where utilities limit the installation of trench PRBs
- Ready access for construction
- Access to sites up gradient or down gradient to allow groundwater monitoring
- Permitting requirements if used in or near wetlands
- Construction cost based on 20-foot spacing between injection wells installed to an overall depth of 40 feet. Deeper installations are possible

Permitting

POTENTIAL PERMITTING AUTHORITIES

- Massachusetts Department of Environmental Protection

ECO-BENEFITS

- Improves Energy Savings / Nutrient Recovery / Recycling
- Improves Management of Flooding / Extreme Events

PERFORMANCE CHALLENGES

- Siting can be limited by wetlands, public utilities and abutter concerns
- Detailed knowledge of local groundwater hydrology needed
- Large projects may require a hydrogeologic investigation and groundwater modeling to estimate effectiveness of PRB
- Permitting requirements may be extensive and time consuming
- Projects may require extensive groundwater monitoring early in the project to quantify nitrogen load reduction
- Projects may require groundwater monitoring near or in embayments as well as monitoring of vegetation and benthic monitoring where groundwater surfaces in the receiving estuary

CLIMATE RESILIENCE: RISKS

- Degradation of materials and reduced asset lifespan due to more frequent inundation and increased exposure to saline water
- Inundation leading to saltwater intrusion into groundwater potentially affecting reuse of water (e.g. irrigation)
- Destabilization of assets as a result of changes in groundwater levels or erosion

CLIMATE RESILIENCE: SOLUTIONS

- Ensure frequent maintenance inspections to monitor asset condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets)
- Select materials and coatings that are able to cope with an increasingly saline environment
- Backflow valves on outlets
- Anchoring of buried assets
- Locate technology outside flood hazard area anticipated for the life of the installation

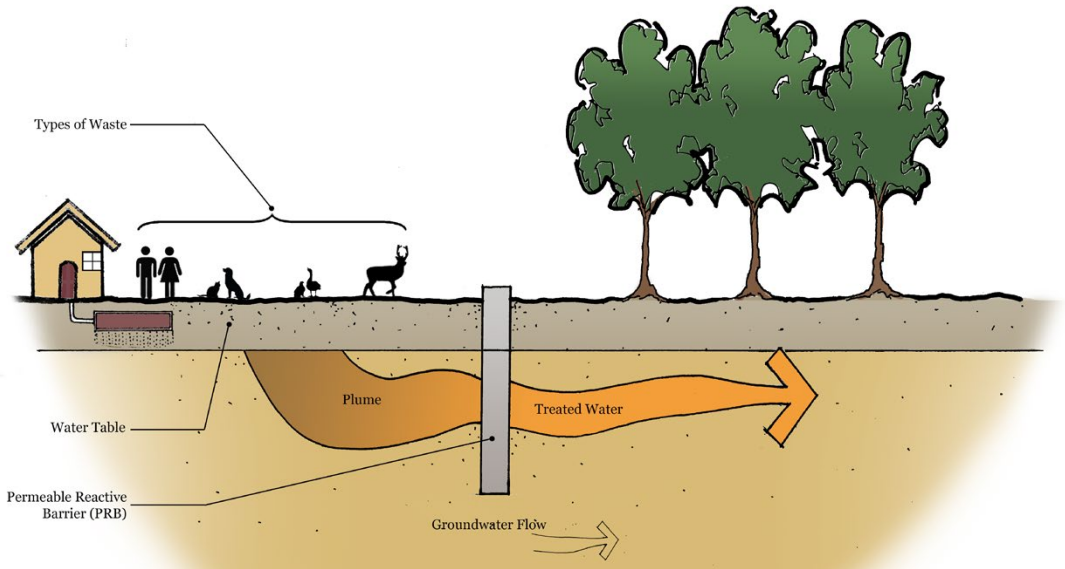

Figure 4-15

Permeable Reactive Barriers (PRBs) Trench Method

PRB

SCALE: SITE/NEIGHBORHOOD
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

A permeable reactive barrier (PRB) is an in-situ (installed within the aquifer) treatment zone designed to intercept nitrogen enriched groundwater. Through use of a carbon source (the PRB medium), microbes in the groundwater uptake the nitrogen, denitrifying the groundwater. The trench method PRB uses large trenching equipment to install a mixture of coarse sand, wood chips, compost and/or other materials (medium) in the trench created by the trencher. The vertical wall can be installed to a depth of 40 feet with a width of 1.5 to 3 feet; PRBs can also be installed in large diameter columns. As groundwater flows through the wall, the medium provides a carbon source for microbes living in the groundwater. The microbes consume the carbon source as well as oxygen, developing an anaerobic environment which releases nitrogen gas to the atmosphere, reducing the groundwater nitrogen load before reaching the estuary.

Technology Performance

Nitrogen Removal 75% to 95%

Phosphorus Removal 50% to 95%

Stormwater Bioretention Soil Media Filters

SCALE: SITE
APPROACH: REMEDIATION

SCENARIO PLANNING: NOT SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Bioretention is the process in which contaminants and sedimentation are removed from stormwater runoff through physical, biological and chemical treatment processes. Stormwater is collected into the treatment area which consists of a grass buffer strip, sand bed, ponding area, organic layer or mulch layer, planting soil, and plants. Runoff passes first over or through a sand bed, which slows the runoff's velocity, distributes it evenly along the length of the ponding area, which consists of a surface organic layer and/or groundcover and the underlying planting soil. The ponding area is graded, its center depressed. Water is ponded and gradually infiltrates the bioretention area or is evapotranspired. The bioretention area is graded to divert excess runoff away from itself. Stored water in the bioretention area planting soil exfiltrates over a period of days into the underlying soils.

PHYTOBUFFERS IDENTIFIED FOR PILOTING

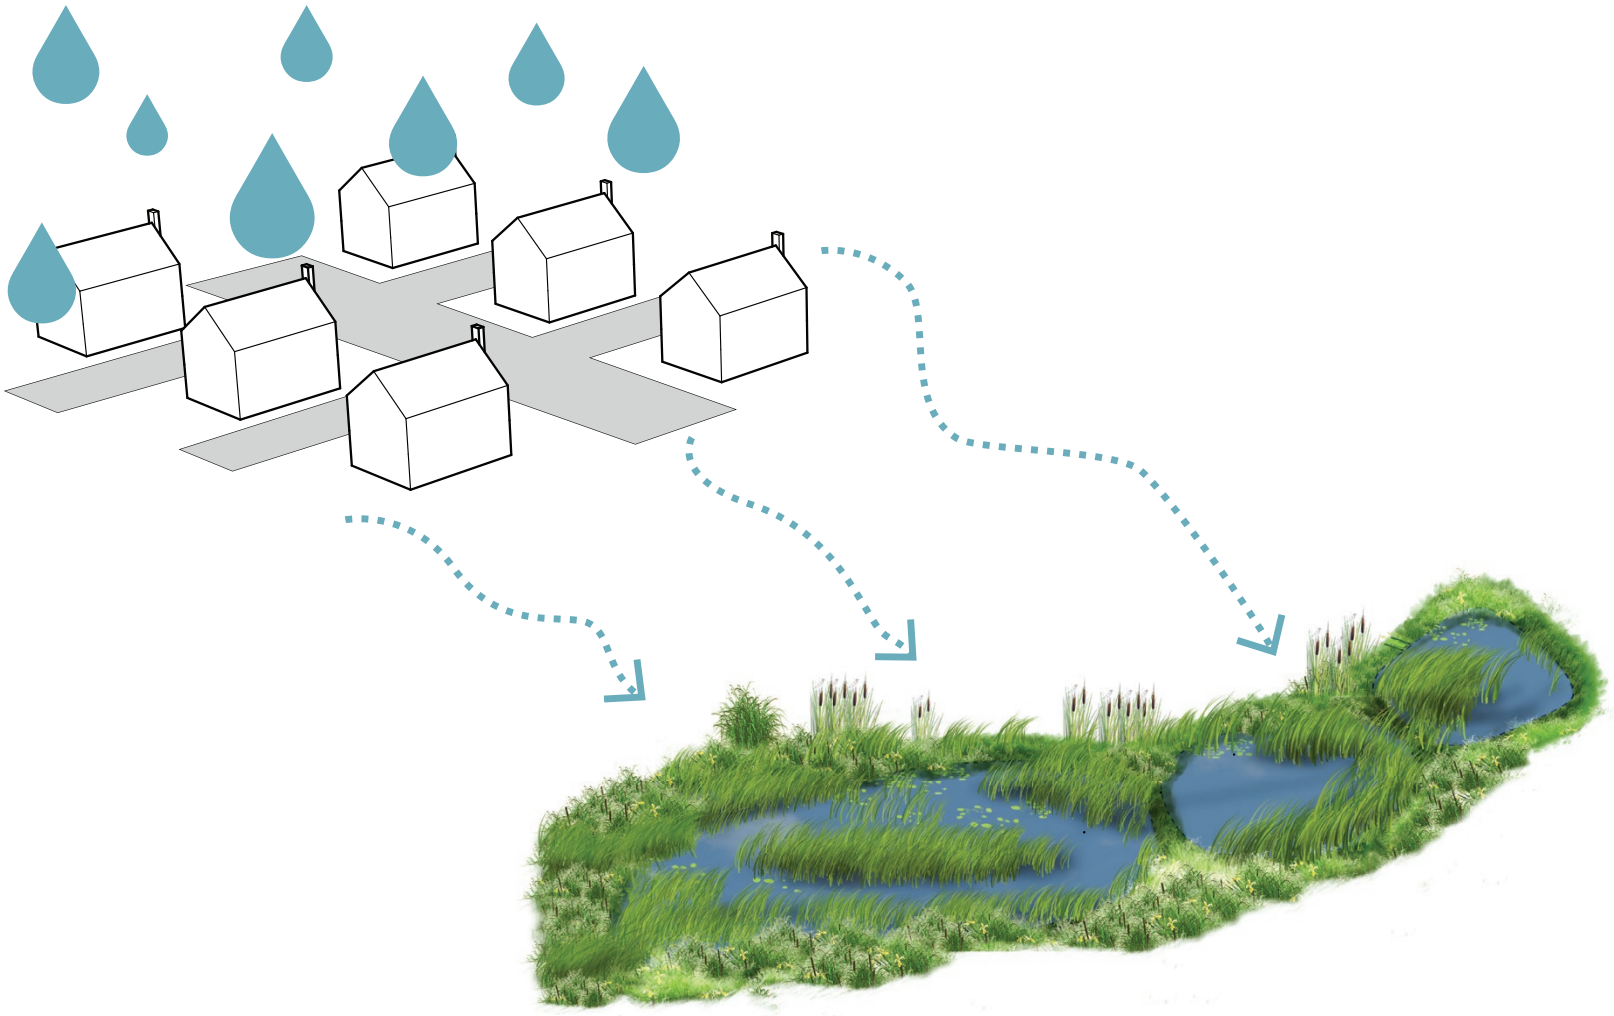

Figure 4-18

Stormwater Constructed Wetlands, BMPs

SCALE: CAPE WIDE
APPROACH: REMEDIATION

SCENARIO PLANNING: SELECTED FOR USE
PHYTOBUFFERS IDENTIFIED FOR PILOTING

DESCRIPTION

There are several types of structural stormwater BMPs, such as phytobuffers, vegetated swales, and constructed wetlands, which can contribute to nutrient removal. These approaches typically employ an excavated elongated basin engineered to accommodate the requirements of the site, together with components designed to enhance nutrient attenuation. These components may include: a swale to convey runoff; a system of chambers that allow for filtration, sediment settling, aerobic and anaerobic activity; and vegetation for nutrient uptake. Vegetated swales are typically grassed parabolic basins with relatively flat side slopes. Phytobuffers employ fast growing poplars and willow trees to remove nutrients and other contaminants. Constructed wetlands filter stormwater as it flows horizontally through a sediment forebay and a series of gravel-bottomed wetland cells, where algae and microbes grow in abundance. Constructed wetlands can be engineered to mimic natural systems, but designed to improve residence time within anaerobic chambers, allowing for year round nitrogen removal.

SITING NEEDS

Aquaculture Mariculture

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: RESTORATION

SCENARIO PLANNING: NOT SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Seaweed and other marine vegetation remove nitrogen from their environment. The cultivation and removal of the marine vegetation can remove nitrogen from an estuary, reducing the estuary's nitrogen load. Mariculture can become a dual purpose project where seaweed can be harvested for market while there will be a local reduction in nitrogen in the overlying water column during the growth and maturation of the seaweed. This method of aquaculture cultivates marine vegetation such as seaweed to remove nitrogen. Harvesting a portion of the vegetation may be required to remove nitrogen. Mariculture can be used in combination with other types of aquaculture as well as floating constructed wetlands designed for brackish water.

Aquaculture Shellfish

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: RESTORATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Shellfish, specifically oysters, remove nitrogen from their environment. The growing and removal of the mature oysters can remove nitrogen from an estuary, reducing the estuary's nitrogen load. Aquaculture can become a dual purpose project where shellfish are harvested for market while there will be a local reduction in nitrogen in the overlying water column during the growth and maturation of the oysters.

Shellfish may be cultivated above or within the estuary bed. The "in-estuary bed" method cultivates the shellfish in the benthic soils of the estuary. Shellfish may also be cultivated above the estuary bed in containters. With either approach, harvesting a portion of the oysters is required to remove nitrogen. Shellfish cultivation may be used in combination with other types of aquaculture (e.g mariculture), as well as floating constructed wetlands designed for brackish water.

Coastal Habitat Restoration

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: RESTORATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

Restoration of coastal habitats includes establishing and/or enhancing estuary salt marshes, eel grass beds, as well as shellfish and oyster beds together as an ecosystem.When considering restoration of coastal habitats, implementing these ecosystems jointly should be considered. The installation of riparian buffer zones and Floating Constructed Wetlands should be considered when restoring coastal habitats. Habitat restoration should focus on creating or rehabilitating habitats, including creating communities that are natural to the area.

Floating Constructed Wetlands

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: RESTORATION

SCENARIO PLANNING: SELECTED FOR USE
IDENTIFIED FOR PILOTING

DESCRIPTION

FCWs are manmade floating "islands" that act as floating wetlands that treat waters within ponds and estuaries. The islands are made of recycled materials that float on ponds or estuaries, exposing the plant's roots to the pond and estuarine waters. The root zones provide habitat for fish and microorganisms while reducing nitrogen and phosphorus levels. The floating islands can also be designed to allow shellfish and seaweed to grow which can be harvested, offsetting some of the systems costs. Some systems circulate surface water through the island, exposing the water to the root zones of the plants. The islands can be installed with shellfish beds and/or salt marsh grasses potentially assisting with their establishment. The islands are generally stationary and can be installed with walkways to access and maintain the plants growing on the islands. The islands require little O&M and do not need to be removed during the winter months, even if freezing water is a concern.

APPROACH: RESTORATION

SCENARIO PLANNING: NOT SELECTED FOR USE

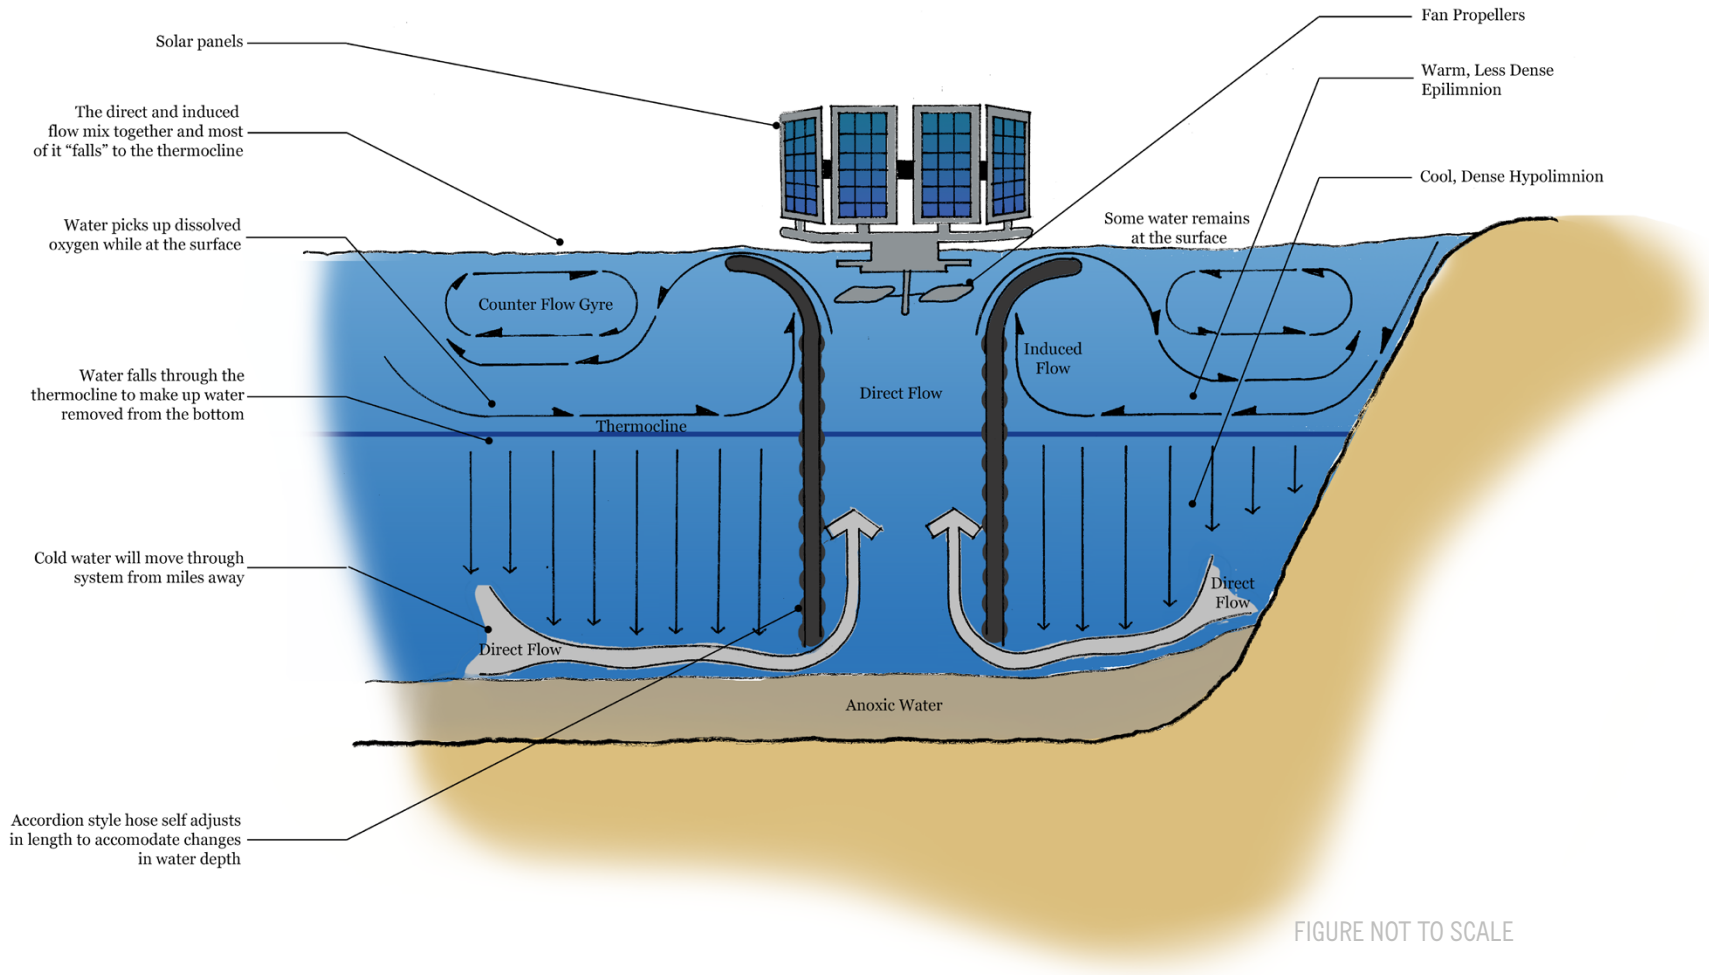

Figure 4-24

Pond and Estuary Circulators

SCALE: NEIGHBORHOOD/WATERSHED
APPROACH: RESTORATION

SCENARIO PLANNING: NOT SELECTED FOR USE

DESCRIPTION

The circulation of pond and estuary water increases the oxygen concentration while reducing nutrients (nitrogen and/or phosphorus) concentrations, reducing odors, and enhancing fish habitat. The circulation is generally performed mechanically by installing solar or electric powered circulators.

Pond and estuary circulators work by reducing stratification in ponds and estuaries. Anoxic conditions can occur within the lower stratified layers leading to harmful algae blooms, fish kills and odors. Circulators mix these stratified layers, thereby increasing dissolved oxygen concentrations throughout the pond depths.

Traditional Approaches for Nutrient Management

There are four categories of traditional infrastructure wastewater systems. These include:

- Individual on-site systems with and without enhanced nitrogen removal
- Cluster systems serving up to approximately 30 homes with aggregate wastewater flows less than 10,000 gallons per day (gpd)
- Satellite systems serving from 30 to 1,000 homes (wastewater flows between 10,000 and 300,000 gpd), intended to treat and dispose of wastewater from one area of a community
- Centralized systems that can provide for most or all of a community's wastewater management needs

These traditional approaches are summarized below; more complete discussions of individual treatment techniques can be found in Appendix 4A; the most detailed and extensive information can be found in the Technologies Matrix, available in Appendix 4B and on the web at: http://capecodcommission.org/matrix.

INDIVIDUAL ON-SITE SYSTEMS

The most common infrastructure on Cape Cod is individual on-site systems. These systems include cesspools, non-Title 5 compliant septic systems, Title 5 compliant septic systems, innovative/alternative (I/A) septic systems and enhanced I/A systems. All of these systems work similarly (**Figure 4-27**). Title 5 systems include a septic tank into which wastewater from households and businesses is discharged, and a distribution box from which effluent from the septic tank flows and is distributed to the soil absorption system (SAS), which releases the effluent to the ground. Cesspools do not include a distribution box, leach field, or SAS. The amount of nitrogen removed through denitrifying septic systems is about 40% and can be somewhat enhanced dependent on the soil type and the distance between the discharge and groundwater. Very sandy soils with little organic material, soils common on the Cape, provide less treatment than other soil types.

When estimating nitrogen concentrations being discharged to groundwater, Title 5 compliant systems have a discharge concentration of 26.25 milligrams per liter (mg/L). This concentration includes all denitrification that occurs in the wastewater within the septic system and in the unsaturated soils as it reaches the water table. The Massachusetts Department of Environmental Protection (MassDEP) approves I/A septic systems for 19 mg/L. This value is typically used when estimating nitrogen reduction for nutrient management plans. Enhanced I/A systems may achieve a greater reduction. I/A septic systems may play a significant role in helping to manage nutrients entering the groundwater.

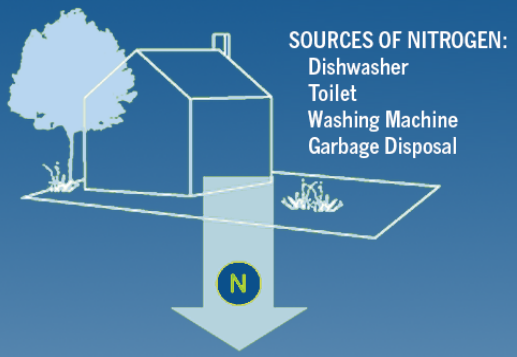
One of the limiting factors in optimizing the performance of I/A systems is variability and inconsistency in maintenance. Outside oversight of I/A systems, potentially at the municipal or county level, could improve performance. Management entities with oversight of private I/A systems can ensure high quality system installation and inspection, maintenance and operation, service provider training and certification, qualified installers and construction inspectors and performance tracking. There are many forms of so-called "Responsible Management Entities" (RME), including public utilities, regional service authorities and county entities, among others. Two US EPA documents – "Voluntary National Guidelines for Management of Onsite and Clustered (Decentralized) Wastewater Treatment Systems" dated March 2003, and "Handbook for Management of Onsite and Clustered (Decentralized) Wastewater Treatment Systems" dated December 2005 – provide useful references for considering management oversight of on-site systems. The establishment of I/A management entities, and the definition of their essential roles and functions, is an area that merits further consideration. Currently, the Barnstable County Department of Health and the Environment (BCDHE) provides a maintenance and monitoring database to assist towns in meeting compliance requirements and the potential to expand this program could be considered.

On-Site Treatment systems

individual on-site systems

Individual on-site systems represent the most common traditional infrastructure on Cape Cod. These systems include cesspools, Title 5 compliant and non-Title 5 septic systems, and innovative/alternative (I/A) and enhanced I/A septic systems and any remaining cesspools.

Wastewater from households and businesses are collected and treated to varying degrees by microbes in these systems. Once treated, the liquid wastewater is discharged, leaving behind small amounts of solid waste.



The soil absorption system (SAS) from a Title 5 system is located at least four feet above the high water table under the discharge area. A Title 5 system has the same general design as a non-Title 5 septic system, but meets MassDEP standards outlined in Title 5 regulations.

of the development on Cape Cod uses septic systems designed for wastewater treatment.

The amount of nitrogen reduction depends on soil type and distance to groundwater. Very sandy soils with little organic material, where are common on the Cape, allow septic system discharges to drain to the water table with less treatment than other soil types.

has standards for maintenance, operation and approval of I/A and enhanced I/A septic systems that nitrogen to 19 and 13 mg/L of discharge.

On-Site Treatment Systems

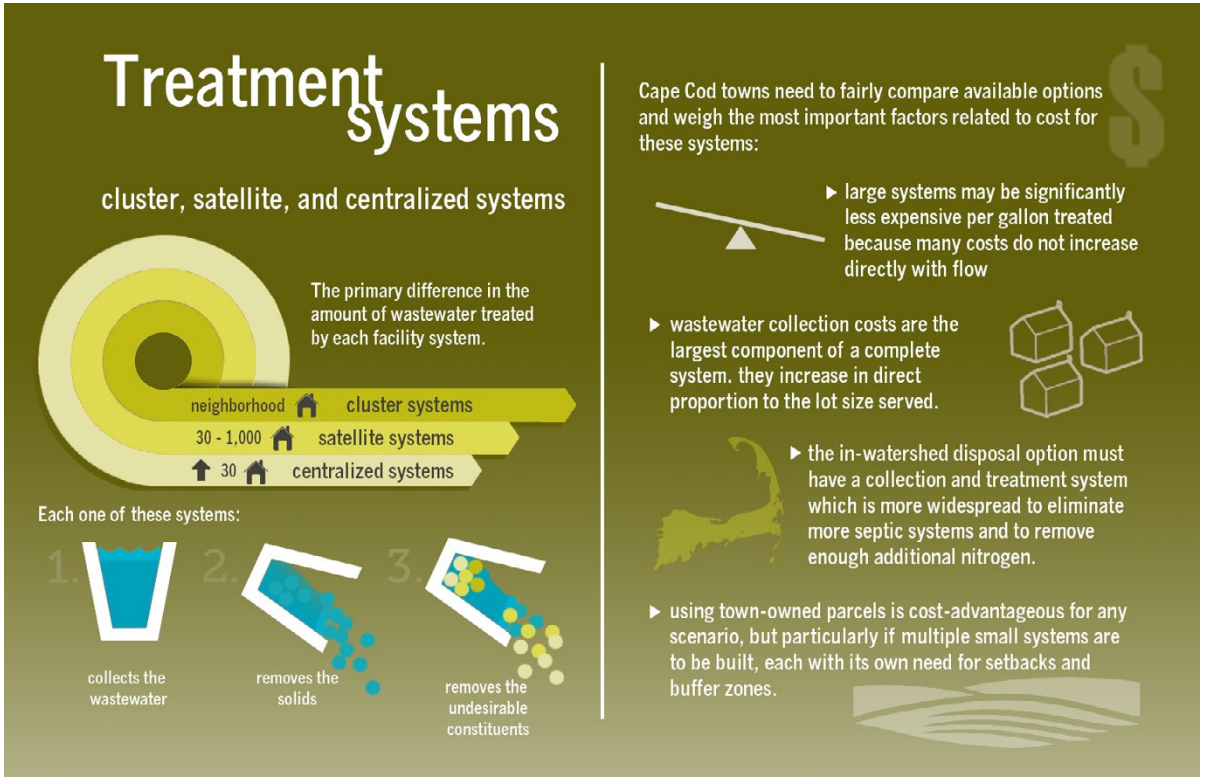
Figure 4-27

CLUSTER, SATELLITE AND CENTRALIZED SYSTEMS

Cluster, satellite and centralized systems all have a series of pipes and sometimes pumps that collect wastewater from multiple households and convey it to a centralized facility for the treatment and disposal of wastewater (effluent) and solids. The primary difference in the facilities is the amount of wastewater each treats. In general, cluster systems treat less than 10,000 gpd, satellite systems treat up to 300,000 gpd and centralized systems treat flows over 100,000 gpd (**Figure 4-28**).

Each of these systems collects wastewater, removes the solids, and through a series of treatment technologies treats the wastewater by partially reducing the undesirable constituents, including nitrogen and phosphorus, prior to discharge to the groundwater, surface water or an ocean outfall. The degree of removal is dependent on the treatment type and degree of treatment designed into the facility. In general, the greater the treatment, the greater the costs to design and build the facility and collection system, operate and maintain the facility, and treat and discharge the wastewater.

The effectiveness of traditional infrastructure can vary and is site-specific. Many wastewater pollutants can be managed with traditional systems, including nitrogen, phosphorus, total suspended solids, biological oxygen demand, pH, suspended metals, total petroleum



Treatment Systems

Figure 4-28

hydrocarbon and pathogens. Traditional systems may be able to remove or manage some contaminants of emerging concern, though which CECs and how well they may be managed is still largely unknown. CECs are addressed in more detail later in this chapter.

Traditional infrastructure generally performs well when operated properly. However, it is possible for these systems to operate below their nutrient reduction potential if not operated properly. Decreases in performance can occur if the design flow is exceeded, the influent contains too much fats, oils or grease, or if the influent contains a compound that compromises the health of the microbes in the system.

ALTERNATIVES FOR EFFLUENT DISPOSAL

Once wastewater is collected and treated at a wastewater treatment facility (WWTF), the treated wastewater (effluent) is generally discharged to surface water or groundwater. There are tradeoffs in selecting sites or approaches for disposing of wastewater, including cost, efficiencies in reducing nutrients in the effluent and thereby meeting total maximum daily load (TMDL) targets and environmental considerations.

Even highly-treated effluent contains some nitrogen. If effluent is disposed of within a watershed with a TMDL as opposed to a location that is not impacted by nitrogen, more septic systems in that watershed must be eliminated or fitted with denitrification systems to meet the TMDL target. If land availability within a town dictates that effluent must be disposed of in public wellhead water supply recharge areas, then a higher level of treatment is needed at sharply increased costs for both capital facilities and operations and maintenance (O&M).

Federal and state laws regulate the dumping of waste into waters of the United States or the Commonwealth. The Massachusetts Ocean Sanctuaries Act of 1990, as amended, (Chapter 132A, §12A-16E, and §18) regulates discharge of wastes, including municipal wastewater, into the Commonwealth's ocean sanctuaries, rivers, and estuaries. As authorized by the federal Clean Water Act, the National Pollutant Discharge Elimination System (NPDES) permit program controls water pollution by regulating point sources that discharge pollutants into waters of the United States. Under this program, new WWTFs on Cape Cod may not discharge effluent to a freshwater body or stream.

The vast majority of WWTFs on Cape Cod are permitted with effluent recharged to the groundwater through beds, fields, or wells designed for specific locations and hydrogeologic site conditions. These conditions include soil characteristics, offset distance between the effluent discharge location and the groundwater layer and the environmental limitations imposed by natural and/or regulatory requirements. See Appendix 4A; Effluent Disposal for more information.

When thinking about siting new wastewater treatment alternatives, effluent disposal can occur at the site of treatment or remotely, depending on the availability of appropriate site conditions. The location of disposal sites may be inside or outside the watershed being served by the WWTF. Effluent transport out of the watershed is a possible option where conditions of the current watershed impose severe limitations or prohibit disposal of wastewater effluent. Looking beyond the borders of a nutrient-sensitive watershed may increase the number of potential disposal sites, may provide overall nutrient-removal efficiencies and may also realize cost efficiencies.

With these considerations in mind, finding disposal sites within direct discharge or outside of wellhead protection areas should rise to the top for Cape Cod communities. Identifying disposal sites will require careful analysis and in-depth community discussions. As a starting point, a GIS analysis may be used to identify sites that meet desirable criteria, including: sites that are outside of nutrient-sensitive watersheds, avoid sensitive resources and other receptors, and/or include under-utilized lands, such as MassDOT or Eversource Energy (formerly NSTAR) rights of way. A recommendation of this plan is the development of a detailed evaluation of effluent disposal options.

> **Recommendation S4.3: The Cape Cod Commission shall provide a detailed evaluation of effluent disposal options by September 2015.**

ECONOMIES OF SCALE AND COST OF TRADITIONAL WASTEWATER TREATMENT

The Barnstable County Wastewater Cost Task Force was established to compile and analyze current local information on the costs to build and operate traditional wastewater systems on Cape Cod. Based on that information, the Task Force developed cost estimates for a wide range of wastewater system sizes and types to help Cape Cod towns fairly compare available options. The estimates are presented in the "Comparison of Costs for Wastewater Management Systems Applicable to Cape Cod," also known as the Barnstable County Cost Report (BCCR). This study was updated in 2014 to reflect additional available data and is included as Appendix 4C.

The application of the results allow communities to identify which options are best for their circumstances and thus streamline their watershed and wastewater planning.

Cost estimates are based on a uniform set of assumptions and supported by a review of actual data. They were prepared to be inclusive of all aspects of wastewater management: collection, transport, treatment, and disposal. Four measures of cost were considered:

- **CAPITAL COSTS:** The cost to design, permit and build the facilities, including land costs.
- **OPERATION AND MAINTENANCE (O&M) COSTS:** The ongoing expenses for labor, power, chemicals, monitoring, sludge disposal, etc.
- **EQUIVALENT ANNUAL COSTS (EAC):** A mathematical combination of O&M expenses and amortized capital costs.
- **COSTS PER POUND OF NITROGEN REMOVED:** The equivalent annual cost divided by the annual nitrogen load removed from the watershed of a nitrogen-sensitive embayment.

Twelve scenarios were developed to combine capital and O&M costs for wastewater collection, transport, treatment and disposal and to compare those costs with the nitrogen removal that can be expected. Costs and performance were estimated both for base cases (with a uniform set of assumptions for all scenarios) and as part of a sensitivity analysis to determine how costs might change with assumptions that are either more or less favorable for each system size.

The sensitivity analysis allows for the identification of the most important cost factors, which are:

- **ECONOMIES OF SCALE:** Large systems may be significantly less expensive per gallon treated because many of the cost components do not increase directly with the flow.
- **DENSITY OF DEVELOPMENT:** Wastewater collection costs are the largest component of a complete system and they increase in direct proportion to the lot size served (**Figure 4-29** shows density, measured by road length between parcels).
- **LOCATION OF DISPOSAL FACILITIES:** An effluent disposal site within a nitrogen-sensitive watershed returns some of the collected nitrogen to the watershed because there is residual nitrogen in the effluent. Compared to a disposal site that is outside of a sensitive watershed, the in-watershed disposal option must have a collection and treatment system which is more widespread to eliminate more septic systems and to remove enough additional nitrogen to offset that returned in the effluent.
- **LAND COSTS:** Land suitable for wastewater management functions is scarce and expensive on Cape Cod. Using town-owned parcels is cost-advantageous for any scenario, but particularly if multiple small systems are to be built, each with its own need for set-backs and buffer zones. Land has been estimated at $250,000 per acre.

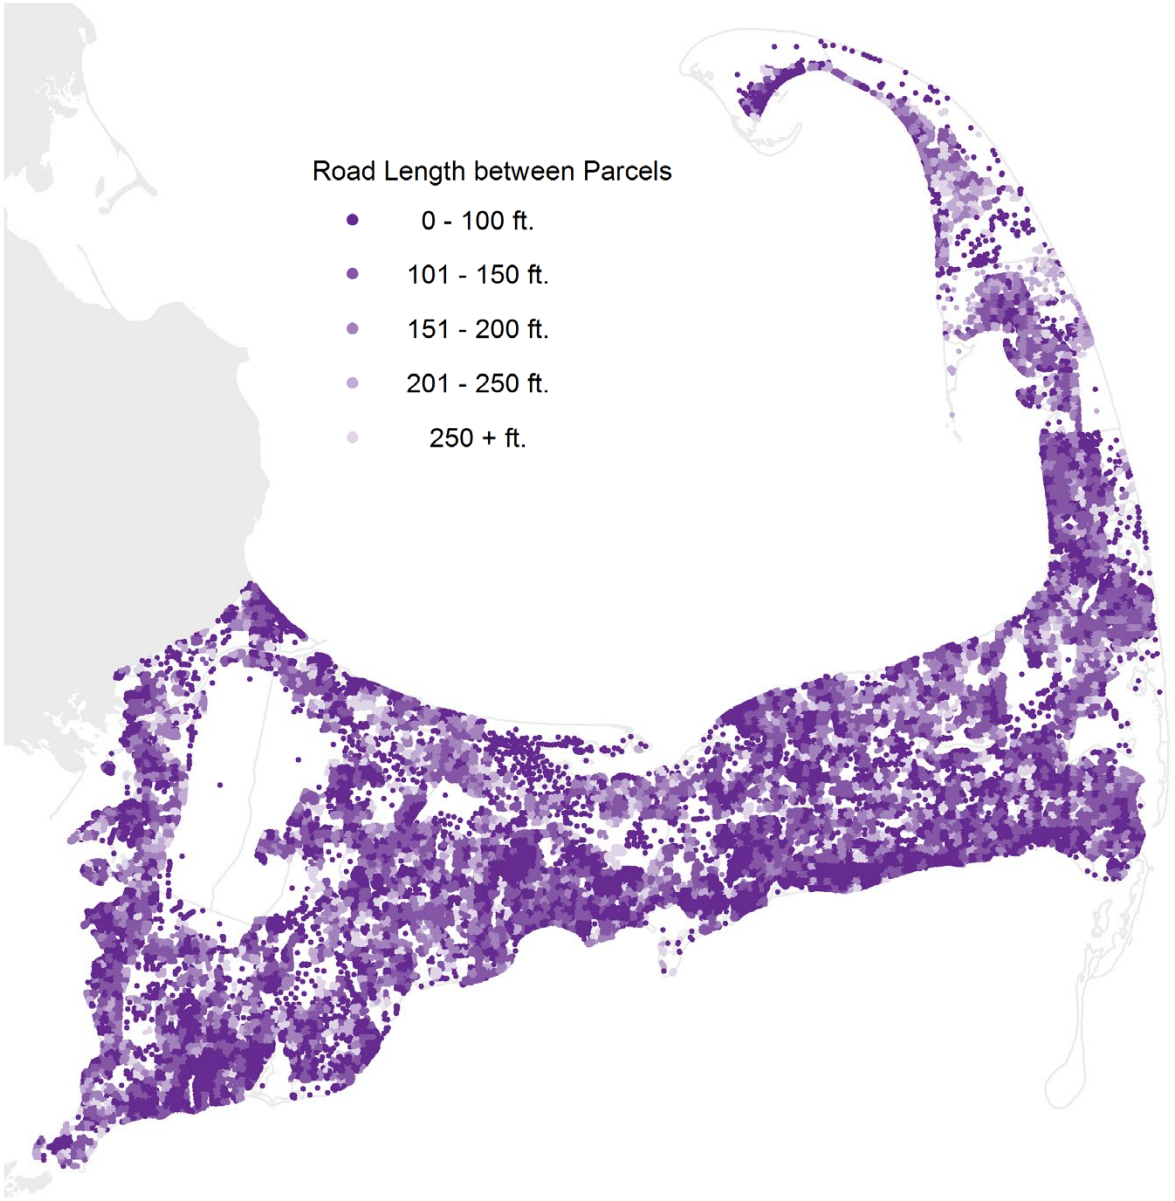
From this sensitivity analysis, conclusions can be drawn about the circumstances that favor one size of system over another.

- **INDIVIDUAL NITROGEN REMOVING SYSTEMS (I/A SYSTEMS):** Their most efficient applicability is within areas of low density and in watersheds that require less than 50% wastewater nitrogen reduction. Their location on the parcel where the wastewater is generated eliminates collection costs.
- **CLUSTER SYSTEMS:** These systems should be considered for existing neighborhoods with small lots that are remote from sewered areas and have publically-owned land nearby. They also are good options for new cluster developments where infrastructure can be installed by the developer and later turned over to the town or for shorefront areas that may not be connected to larger-scale systems until later phases of a project.
- **SATELLITE SYSTEMS:** Satellite facilities make the most economic sense in remote watersheds (more than five miles from existing sewer systems or other areas of need), with vacant publically-owned land nearby. These systems are also applicable when existing or proposed private facilities can be converted to public operations and expanded to provide wastewater services to existing nearby properties on septic systems.
- **CENTRALIZED SYSTEMS:** This option is likely to be the most viable when:

- Dense development exists in nitrogen sensitive watersheds;
- Suitable treatment and disposal sites (outside sensitive watersheds and water supply recharge areas) are available at no or low cost;
- A high degree of nitrogen remediation is required;
- Areas of dense development in sensitive watersheds are within three miles of desirable effluent treatment and disposal sites; and
- Opportunities are available for cost reductions through regionalization.

Given the lack of required collection systems for the non-traditional technologies and approaches, traditional approaches are more likely to benefit from optimizing the factors described above. However, some non-traditional technologies, such as waste reduction toilets, may benefit from regional management arrangements for O&M. For example, a regional effort for managing urine and compost removal and/or reuse, as opposed to a town-by-town or even homeowner-by-homeowner arrangement, may present a cost savings.

Taking advantage of existing inter-municipal arrangements for water and/or wastewater is another potential cost savings method. For example, the Upper Cape Regional Water Supply Cooperative is a regional agreement to supply water to the four Upper Cape towns of Bourne, Falmouth, Mashpee and Sandwich. Management of the Cooperative is by a Board that represents the four public water supply systems – the Town of Falmouth, Bourne Water District, Mashpee Water District and Sandwich Water District. The wells for the Cooperative are located toward



Density as Measured by Road Distance Between Parcels

Figure 4-29

the north end of Joint Base Cape Cod (JBCC), in the town of Sandwich. JBCC is also the site of a federally-owned wastewater treatment facility with the potential to support regional wastewater management needs of the Upper Cape. Potential benefits could be realized in this area given the existing inter-municipal arrangement for water supply and the existing infrastructure at JBCC. More information on the JBCC infrastructure can be found in Chapter 7.

Growth Management Tools

Several planning tools are available for directing growth to appropriate locations where suitable infrastructure exists to support the resource use and wastewater management needs of development and/or where the impact to the environment is not as great. Land use tools such as compact and open space development, transfer of development rights, and nutrient reducing development may be utilized to manage growth and more efficiently utilize resources. These concepts are discussed in more detail in Chapter 7.

Merits of Traditional and Non-Traditional Nutrient Management Approaches

Using traditional technologies to manage wastewater on Cape Cod can offer many benefits, in the right setting. Traditional collection systems and treatment plants can reduce nutrient loads in wastewater before they hit groundwater. They can provide predictable and reliable levels of nutrient removal; they can provide infrastructure that may be retrofitted in the future to address contaminants of emerging concern (CECs), pharmaceuticals, and salt water intrusion. However, traditional technologies may not always offer the most cost-effective solution. Much of Cape Cod sprawls at a low density over miles of roadways, and the cost of installing collection systems may be prohibitively expensive. Additionally, traditional technologies can't remediate the concentration of nitrogen already in the groundwater and estuaries and embayments. Decades of disposal of nutrient-rich wastewater from Cape Cod septic systems resulted in concentrations of nitrogen and other contaminants that will take decades to migrate via the groundwater to ultimately discharge into the Cape's coastal waters. Approaches that remediate nutrient impacts in or adjacent to affected water bodies are important components of efficiently addressing water quality problems.

Many non-traditional techniques offer the promise of remediating water quality within the affected embayment or estuary, thereby having a more immediate result. Non-traditional technologies can intercept and remediate nutrient-laden groundwater close to the water body, or can remediate water in-situ, potentially resulting in faster water quality improvement. In addition, non-traditional approaches can have collateral benefits in the form of creating or improving habitat, one of the desired outcomes of implementation of the Section 208 Plan Update. Because many of the alternative approaches are ideally sited within impacted water bodies and employ natural systems to improve water quality, there is minimal or no water transport between watersheds. Remediation of water quality within coastal resource areas will likely provide additional ecosystem benefits as the "performance" of the coastal resources is enhanced. However, stakeholders have expressed concern about the reliability and/or performance of many of these non-traditional approaches. Many technologies are untested on Cape Cod. Research suggests that some alternative technologies could have widely ranging performance. Performance can be affected by seasonal temperatures, disease, storm damage or poor siting choices. Pilot projects will be needed to identify technologies that can be successfully, and reliably, employed on Cape Cod to remediate water quality.

Water Reuse

Over 97% of water on earth is salty and nearly 2% is locked up in snow and ice. That leaves less than 1% of water for human uses such as drinking, growing crops, household uses and commercial/industrial processes. This limited resource has driven the need for wastewater reuse.

The most common form of wastewater reuse is for non-potable purposes or water which is not used for direct human consumption. Treated wastewater is reused for beneficial purposes such as agricultural and landscape irrigation, industrial processes (such as cooling), toilet flushing and replenishing a groundwater basin (known as groundwater recharge). The quality of wastewater effluent to be reused is treated to standards, criteria and regulations considering the planned reuse.

"Gray water" is the term for the reuse of wastewater that originates from bathroom sinks, bath/shower drains and clothes washing equipment drains. Gray water can be reused onsite as a source of landscape irrigation. Recycled water can satisfy most water demands, as long as it is adequately treated to ensure water quality appropriate for the use. As for any water source that is not properly treated, health problems could arise from drinking or being exposed to recycled water if it contains disease-causing organisms or other contaminants.

Given the challenge of identifying new wastewater disposal sites, the reuse of treated effluent on Cape Cod should be considered in watershed solutions. MassDEP has promulgated regulations defining the reuse of treated wastewater depending on its final disposition. See Appendix 4A; Wastewater Reuse for more information.

Septage

Some significant percentage of wastewater generation will continue to rely on septic systems, at least into the foreseeable future. Consequently, there will continue to be demand for septage treatment. In the near future Barnstable County anticipates the release of the Septage and Food Waste Market Study prepared for the Town of Orleans by Stantec. Similar studies may be appropriate in other parts of the Cape to address the demand for septage processing, identify available facilities, and assess capacity. See Appendix 4A; Solids Collection, Treatment and Disposal Technologies for more information.

Recommendation I4.4:
Barnstable County or towns should commission septage studies to evaluate the demands for septage treatment.

Resiliency to Climate Threats: Sea Level Rise and the Potential for Increased Storm Severity

Massachusetts' climate has changed and will continue to change over the course of the next century. Winter temperatures are increasing and extreme summer heat events are becoming more frequent (Massachusetts Climate Change Adaptation Report, Massachusetts Executive Office of Energy and Environmental Affairs and the Adaptation Advisory Committee, 2011). The high emission scenario of the Intergovernmental Panel on Climate Change (IPCC), predicts that Massachusetts will experience a 5-10°F increase in average ambient temperature by the end of the century. The report cites further predictions that there will be 28 days each year that reach above 100°F, compared to only two days annually today.

Climate change will also affect water resources and coastal processes in Massachusetts. Under very conservative estimates, sea level will rise approximately 10 inches per century, which will increase the height of storm surge and associated coastal flooding frequency, inundate low-lying coastal areas, and amplify shore-line erosion. Even with successful mitigation strategies, these climate trends will continue for generations and new trends, such as increased intensity of hurricanes, are expected to emerge.

Cape Cod is vulnerable to these changes in climate. With 586 miles of tidal shoreline and only 10 miles of land at its widest point, the entire peninsula is vulnerable to the forces of storm activity, sea-level rise and catastrophic forces of hurricanes and nor'easters. The National Climate Assessment has documented an increase in heavy downpours, or extreme precipitation events, since 1958 in the Northeast region of the United States. Sea level rise will increase the region's risk to coastal flooding especially when coupled with extreme precipitation events and increases in hurricane intensity. Also, as a result of sea level rise, water levels will rise and damage infrastructure and property along the Cape Cod coastline.

While the effects of climate change are projected to occur in the distant future, it will take years to develop and implement adaptation strategies for the region. The Section 208 Plan Update provides an opportunity to determine how to adapt the region's water infrastructure to changes in climate, particularly as siting and construction of new infrastructure are considered.

The Association to Preserve Cape Cod, in partnership with the US Geological Survey (USGS) and the Cape Cod Commission, is conducting an assessment of the impacts of sea level rise on groundwater conditions in the Sagamore and Monomoy Lens. This study will assist the Commission

and towns in identifying vulnerable areas for proper infrastructure management. The results are anticipated in 2016.

An assessment of the threats to, and resiliency of, each nutrient management technology to the primary climate-related risks anticipated on Cape Cod was developed as part of this plan. For example, many of the techniques that rely on biological communities may benefit from increased air and ocean temperatures, improving performance through lengthened growing seasons. At the same time, anticipating increased intensity of downpours suggests that stormwater systems should be designed to accommodate higher runoff volumes.

In assessing the technology options, the following possible climate-related risks were identified:

- Damage to, or increased degradation of, structures and materials.
- Mobilization of contaminants into the environment as a result of storage system failures.
- Backflow of saline water into wastewater systems causing overflows, increased degradation of materials and change in biological processes.
- Reduced effectiveness of biological processes as a result of more frequent inundation or exposure to saline water.
- Destabilization of wastewater infrastructure as a result of change in groundwater levels or erosion.
- Restricted ability to access systems to collect outputs or re-use outputs due to salinity.

The following solutions were identified to help minimize the impact of the identified risks:

- Design systems to avoid hazard areas, or allow migration of vegetation as hazard areas change.
- Select materials, coatings and species that are able to cope with an increasingly saline environment.
- Install backflow valves on systems
- Anchor buried infrastructure
- Ensure frequent maintenance inspections to monitor infrastructure condition (e.g. rate of corrosion) and performance of technology (i.e. achieving nutrient removal targets).
- Use protective structures to reduce wave or wind impacts to systems.

See Appendix 4A; Sea Level Rise and Storm Surge Risks to Technology Options for more information and Appendix 4D for a summary of the risks and solutions that are relevant to each technology option that was assessed.

Ocean Acidification

Ocean acidification (OA) is one of the lesser-understood effects of increased carbon dioxide in the atmosphere. According to some research, one quarter of fossil fuel emissions fall on the ocean, causing it to acidify. There is evidence that acidification of the oceans may have significant impacts on ocean ecosystems. Shellfish growers in the Pacific Northwest have observed declining oyster harvests linked directly to ocean acidification. Scientists have documented poor shell development in certain classes of plankton under increased ocean acidity (WHRC Ocean Acidification and Southern New England Conference, October 2014). As ocean pH declines in ocean waters, direct impacts may be observed in some marine organisms, disrupting estuarine and marine ecosystems, affecting the fishing economy, and possibly having adverse effects on some of the technologies that have shown promise in mitigating the nutrient loading problems in coastal waters. More research is needed to understand the effects of ocean acidification on shellfish and other organisms on Cape Cod. In the meantime, OA should be recognized as one of the potential challenges in implementing restoration-based techniques over the long-term.

Contaminants of Emerging Concern

Contaminants of emerging concern (CECs), as described in Chapter 2, include chemicals found in the environment where the risk to human health and the environment is not well known. The US EPA identifies CECs, including pharmaceuticals, personal care products, polybrominated diphenyl ethers (PBDEs) and perfluorinated compounds (PFCs) as requiring further study. The US EPA has undertaken national testing for CECs in public water supplies, referred to as the Unregulated Contaminant Monitoring Rule (UCMR). Monitoring is required for

supplies serving over 10,000 connections or by voluntary action. A number of water suppliers have volunteered to have their supplies tested. As data becomes available through the UCMR the US EPA will be able to target more prevalent contaminants for review, research and action.

Several stakeholders have raised questions about how the technologies considered for water quality remediation might address CECs, and how the plan will address this growing concern. There is still a lot to understand before action can be taken: what priorities to set, what technologies can address the priority contaminants, and what other actions to take to prevent the introduction of CECs into the waste stream. The study and regulatory changes that may be needed are outside the scope of this plan update, but should be the continuing focus of federal and state research and regulatory bodies.

Identifying Suitable Locations for Non-Traditional Technologies: GIS Screening Analysis

The alternative technologies offer different opportunities and limitations for application in the development of watershed-based solutions. Many of the considerations for siting a technique are based on the physical characteristics of the land. During the section 208 planning process, identifying viable potential sites for specific nutrient management techniques became an important objective in understanding the opportunities for using alternative technologies on Cape Cod. With this goal in mind, criteria were selected that define the necessary characteristics for identifying an appropriate site for a particular alternative technology. These criteria were then applied through a Geographic Information Systems (GIS) parcel analysis to rank potential sites for their suitability to support a given technology, and illustrate these opportunities in a map. These GIS site screening analyses have been performed for several alternative technologies, including:

- Constructed wetlands
  - For wastewater treatment
  - For groundwater treatment
  - Saltwater wetland expansion, migration, or restoration
- Phyto-technology
- Permeable reactive barriers - injection well
- Permeable reactive barriers - trench
  - Trench type along roads
  - Trench type in areas other than along roads

The results of these analyses, as well as relevant resource information, will be made available as a resource through the Watershed Team technical assistance program, as described in Chapter 5. Additional GIS screening analyses are needed for additional technologies.

More detailed information on the criteria identified for each technology and how the screening was applied may be found in Appendix 4E.

Selection of Pilot Projects

Many of the practices identified for nutrient management need to be piloted locally in order to determine their effectiveness and identify with more certainty potential construction and operation and maintenance costs. Some of the techniques collected in the Technologies Matrix show more promise for positively contributing to nutrient management on Cape Cod than others. The most promising practices have been identified as such in the summary descriptions presented earlier in this chapter.

Many of these, however, require site-specific evaluation to determine their applicability on Cape Cod, and are recommended for piloting. To minimize risk and avoid having many communities expend funds and time to design and install technologies that may not perform as hoped, a small number of pilot projects should be implemented in settings that allow for fair evaluation of performance. Site selection and pilot project design should also ensure that the results may be transferred to other Cape Cod settings, to the extent feasible.

As part of the Section 208 Plan Update, the Cape Cod Commission suggests that criteria for identifying and evaluating potential technologies and specific sites eligible for pilot programs on Cape Cod be established.

Recommendation S4.5: The Cape Cod Commission, in conjunction with MassDEP, shall establish criteria for eligible pilot projects.

The criteria should include factors that will ensure that the pilot projects fairly evaluate performance, and also allow for transferability among Cape Cod communities .

Recommendation S4.6: In coordination with US EPA and MassDEP, the Cape Cod Commission shall work with communities, state and federal agencies to identify opportunities to implement pilot projects in suitable locations across Cape Cod.

Several locally supported pilot projects are in progress or anticipated by the towns and are discussed in more detail in Chapter 2. These include aquaculture in Wellfleet, Falmouth and Mashpee, eco-toilets in Falmouth and testing of I/A systems by the BCDHE at the septic system test center.

The United States Environmental Protection Agency (US EPA) received $2 million in funding in FY14 to begin implementing the Southeast New England Coastal Watershed Restoration Program (SNECWRP). SNECWRP is a partnership among public and private stakeholders collaborating to create a broad ecological and institutional framework for protecting and restoring the coastal and watershed area in Connecticut, Rhode Island and Massachusetts.

In FY14, the two National Estuary Programs (NEPs) – Narragansett Bay and Buzzards Bay – awarded $723,869 and $728,559, respectively, on behalf of SNECWRP for projects in their study areas. The Buzzards Bay NEP awards included a $50,000 award to the Buzzards Bay Coalition to fund restoration efforts in Red Brook Harbor in Bourne through the development of a public-private partnership that will supply wastewater treatment to an existing development and a $250,000 award to the Town of Falmouth to upgrade septic systems adjacent to West Falmouth Harbor. An additional $500,000 in technical assistance through a US EPA contract was awarded to the towns of Barnstable and Chatham to develop preliminary stormwater best management practices (BMPs). Project selection required an emphasis on demonstrating early environmental success and/or laying the groundwork for more expansive efforts in the near future. It is anticipated that similar future federal funding will be available to support pilot projects in the region.

Monitoring

Monitoring for water quality improvements and performance of technologies will be necessary elements of implementing the Section 208 Plan Update. Monitoring is important to measure progress toward meeting water quality goals; it will provide baselines and metrics for adjusting a watershed approach through an adaptive management plan. This section summarizes some of the necessary components of monitoring for water quality improvement on Cape Cod.

EXISTING MONITORING

All of the embayments studied by the Massachusetts Estuaries Project (MEP) have established stations that were monitored for a period of three years or more for development of the technical reports. Monitoring of embayment water quality is continuing on a year to year contract basis with some towns, but a number of programs have been reduced or discontinued. The Cape is fortunate that many ponds continued to be monitored through the Pond and Lake Stewardship (PALS) program and that specific pond assessments and restoration projects are proceeding. Drinking water supplies and wastewater treatment facilities continue to be monitored through state permitting programs. Some stormwater outfalls are monitored as part of NPDES compliance and more monitoring will likely be required under the proposed draft Municipal Separate Storm Sewer Systems (MS4) permit. In many cases, active monitoring programs rely heavily on citizen volunteers. The development of watershed scenarios will require baseline monitoring of affected water bodies to establish water quality metrics and goals. Ongoing monitoring specific to informing whether progress is made toward meeting watershed goals or an individual pilot project's performance will need to be customized to the setting.

NON-TRADITIONAL TECHNOLOGY MONITORING

The need to better understand the effectiveness of non-traditional technologies will require rigorous technology-specific performance monitoring. At a minimum, a

monitoring protocol should include an assessment of downgradient resources or sensitive receptors, placement of monitoring stations, parameters of evaluation, methods for collecting and analyzing data, and frequency of data collection. Reasonable time frames for piloting a project must be established, and should take into account:

- acceptable timeframes for achieving water quality goals,
- extent of water quality degradation,
- anticipated time for performance, and
- occurrence of anomalous events, such as hurricanes or other weather.

Monitoring protocols for non-traditional technologies are in development. These draft protocols will be made available in a technical guidance document by September 2015. Specific protocols will need to be developed as pilot projects move forward.

Monitoring to understand the impacts of stormwater infrastructure upgrades and the effectiveness of fertilizer reduction programs will also require site-specific monitoring and extrapolation of performance and compliance monitoring results to determine effectiveness.

Recommendation I4.7:
Performance monitoring shall be required for all technologies.

MONITORING COMMITTEE

With the extensive monitoring required to implement the Section 208 Plan Update, an ad hoc Monitoring Committee was established in April 2014 to review monitoring needs and make recommendations. The Monitoring Committee has discussed non-traditional technologies and characterized general monitoring approaches for piloting. The Committee is developing eight conceptual protocols for aquaculture, shellfish bed restoration, inlet widening, permeable reactive barriers, innovative/alternative septic systems, eco-toilets and constructed and floating wetlands. The Committee has been working to identify criteria for selecting and prioritizing pilot projects of nutrient remediation technologies, as well as developing a strategy and framework for evaluating the performance of these technologies. It is anticipated that monitoring data collected from the pilot projects will support updates to the Technologies Matrix. The Committee is also charged with developing specific recommendations for improving baseline and compliance monitoring in the region and identifying needs and services that will be necessary to support implementation of the Section 208 Plan Update. Committee recommendations will be detailed in a technical guidance document and implemented through permit conditions at the state and regional levels.

Recommendation I4.8: Draft monitoring protocols for non-traditional technologies shall be provided by the Cape Cod Commission based on input from the Monitoring Committee in a Technical Guidance document by September 2015.

It is recommended that the ad hoc Monitoring Committee become a standing committee and continue to support implementation of the Section 208 Plan Update. In addition, the Committee should identify and track developing issues (such as contaminants of emerging concern, or climate change) that may affect performance of technologies, or progress toward improving water quality in coastal embayments.

Recommendation I4.9: The Cape Cod Commission shall create a standing Monitoring Committee to support implementation of the plan and identify and track developing issues, such as CECs and climate change impacts to technology performance, subject to available resources.

DATA WAREHOUSE

Data collection to demonstrate progress toward water quality goals presents both an opportunity and a challenge. As conceived in this plan, the extensive monitoring recommended will result in large quantities of data that will need to be stored, managed, and made accessible to the public. A data warehouse and "custodians" are needed: significant storage capacity will be needed, as well as the structure to support the data, and a web-based interface. Technical studies, reports, and maps that may be generated as a result of data analysis will need to be housed and made available to the public. To date, monitoring data has not been readily available on Cape Cod.

The Commission's Strategic Information Office (SIO) currently maintains an expansive data warehouse, and the Commission's Watershed Management Program maintains a regional historic warehouse of water resources information on behalf of Barnstable County and the 15 towns. Data hosting and maintenance would be available for a robust monitoring program providing consistent and accurate data feedback loops among the towns and appropriate agencies. This Plan Update recommends that the Cape Cod Commission assume responsibility for monitoring and maintaining regionally consistent data sets that are freely accessible to the public. Maintaining data in a centralized, accessible location will allow information to transfer from one project to another, and assist the region in prioritizing projects based on water quality improvements and/or further degradation.

Recommendation I4.10: A regional water quality monitoring program and data warehouse shall be established and the Cape Cod Commission shall assume responsibility for monitoring and maintaining regionally-consistent data sets that are freely accessible to the public, subject to available resources.

05 EVALUATION

The Cape Cod Model - Regional Watershed Analysis

A watershed approach looks at the jurisdiction of the problem – watersheds. Of the 53 watersheds to coastal embayments on Cape Cod, 32 are shared by more than one town. The current regulatory process often requires town wide planning which, in many areas, represents only a partial solution to the problem. This document outlines a technical review process designed to provide insight into new and innovative ways of implementing solutions at the watershed level. Conversations to date have resulted in polarizing local debates, sometimes discussed in terms of centralized versus de-centralized approaches or traditional solutions versus alternative solutions. One of the key distinctions depends on a considered option's reliance on a permanent physical connection among multiple sources, a collection system. The process outlined in this report grouped points of view associated with these categorizations into two approaches to solving Cape Cod's nitrogen problem: a traditional approach and a non-traditional approach.

TEAM 1

Collection Systems

cost and effectiveness
septic nitrogen load
economies of scale
potential limitations
permittable

Traditional Approaches

TEAM 2

Non-Collection Systems

total controllable nitrogen load
watershed/embayment options
innovation
nitrogen reduction credits
no collection

Non-traditional Approaches

Scenarios define the outer bounds of an adaptive management plan

EVALUATION

Chapter 5: The Cape Cod Model - Regional Watershed Analysis

The regional analysis of watersheds began with a review of local nutrient management planning, consideration of the best available scientific assessments and the collection of all relevant geographic data. Most Cape Cod communities have been engaged with nitrogen planning but few have moved forward to construct watershed scale projects capable of protecting and restoring water quality.

It's not a lack of awareness on the issue. Many local decision-makers have an understanding of the nitrogen problem and the accompanying environmental and economic threats. Wastewater always ranks high in surveys inquiring about the biggest challenges for the region. Education is important, but it's not the reason communities have struggled to address the problem.

Image on facing page: The Section 208 Plan Update utilized two different technical teams to develop two different approaches in each watershed. The outcome is a hybrid process that considers both traditional and non-traditional technologies together in a watershed. Together, this process reflects the outer bounds of an adaptive management plan with a locally preferred combination of technologies for implementation.

It's not an engineering problem either. There are many engineering solutions that will remove enough nitrogen to meet standards. Many towns have offered such plans only to have them rejected by voters.

Existing regulation drives a traditional wastewater planning process, producing a predictable and narrow set of point source solutions to a non-point source problem without point source enforcement action. This creates an equally predictable implementation problem. The local communities sense the mismatch and resist the proposals. The existing regulatory framework is part of the problem.

It's a design problem. Proposed solutions have to be designed with more emphasis on the cultural identity of the community involved. The process should examine an expanded number of options and develop a range of simulated outcomes communicated in a geographic context with greater public participation and community engagement. The Cape Cod Commission, in the technical review and regional watershed analysis, piloted this approach. Lessons learned inform a recommended process for local communities in developing achievable water quality solutions by promoting efficient and effective watershed planning, expanding technologies and policies available to communities, and using new decision support tools to empower citizens and stakeholders.

A New Approach

Cape Cod's geology, density patterns and lack of existing infrastructure support a new approach to addressing water quality goals in the region. The Section 208 Plan Update suggests a new approach to gain consensus earlier in the process, to ensure that shared watersheds are addressed, and to better coordinate needed infrastructure expenditures with municipal budgets. Striving for stakeholder consensus early in the planning process, including consensus on the range and locations of technologies to be employed, will lead to more community support during implementation than Cape Cod communities have seen to date. Watershed scenarios should include more detailed discussions about the development of adaptive management plans to

identify phasing strategies for implementation, the risks and benefits associated with each technology, piloting and monitoring necessary to support the approach, and the ability of a community to pay for the solution.

The regional watershed analysis creates a framework for local decision-making. It does not attempt to produce a preferred solution, but instead provides decision-support tools to help define a range of possible options to meet water quality standards, leaving the selection of specific strategies to the local communities closest to the problem.

This approach integrates science, design and information. Evaluating environmental problems in a geographic context with active stakeholder participation and collaboration, the process interactively considers issues of representation, process, change, impact, evaluation and decision-making.

DECISION SUPPORT TOOLS

The Commission developed a number of decision support tools, using data described in Chapter 4, to facilitate the creation of watershed scenarios and adaptive management plans. These new decision support tools and the supporting databases and methodologies will be available through the Cape Cod Commission's Watershed Team technical assistance program discussed later in this chapter. Some are still in development and/or undergoing beta testing. These tools make complex data sets easier to understand and provide an avenue for increased informed deliberation at the local and hyper-local planning levels, expediting the selection and implementation of watershed solutions.

Tools related to scenario development include the following:

- **WATERSHEDMVP (MULTI-VARIANT PLANNER):** A dynamic web-based, geospatial scenario planning tool developed by the Cape Cod Commission that allows technical experts and the general public to compare various water quality management options at scales ranging from the neighborhood, watershed and subregional level (www.watershedmvp.org).
- **WATERSHED TRACKER:** A companion tool to WatershedMVP that tracks nitrogen loads and interventions chosen by the user.
- **SITE SCREENING VIEWER FOR NON-TRADITIONAL TECHNOLOGIES:** A geographic information systems (GIS)-based data analysis of non-traditional technologies and approaches to weigh potential nitrogen attenuation enhancements, improvements to existing green infrastructure networks and conditions necessary to maximize effectiveness.
- **WATERSHED CALCULATOR:** A tool used to track cumulative nitrogen reductions and cost through the layered application of technologies in a watersheds to meet reduction targets.
- **TECHNOLOGIES MATRIX:** A flexible, dynamic and continually updated source of performance and cost information on currently available technologies and approaches for reducing nitrogen from wastewater, groundwater and saltwater and their applicability for use on Cape Cod.
- **SCENARIO ASSESSMENT MODEL (SAM):** A web-based assessment and decision model that allows communities to identify priorities and evaluate scenarios in terms of social impacts, reliability of solutions, and cost considerations.
- **BARNSTABLE COUNTY COST REPORT UPDATE:** The 2014 update by AECOM to the 2010 report "Comparison of Costs for Wastewater Management Systems Applicable to Cape Cod" by the Barnstable County Wastewater Cost Task Force (2010 report prepared by the Barnstable County Wastewater Cost Task Force) on Cape-wide collection, treatment, disposal, and non-traditional approaches prepared to provide an updated basis for financial decisions in the Section 208 Plan Update.

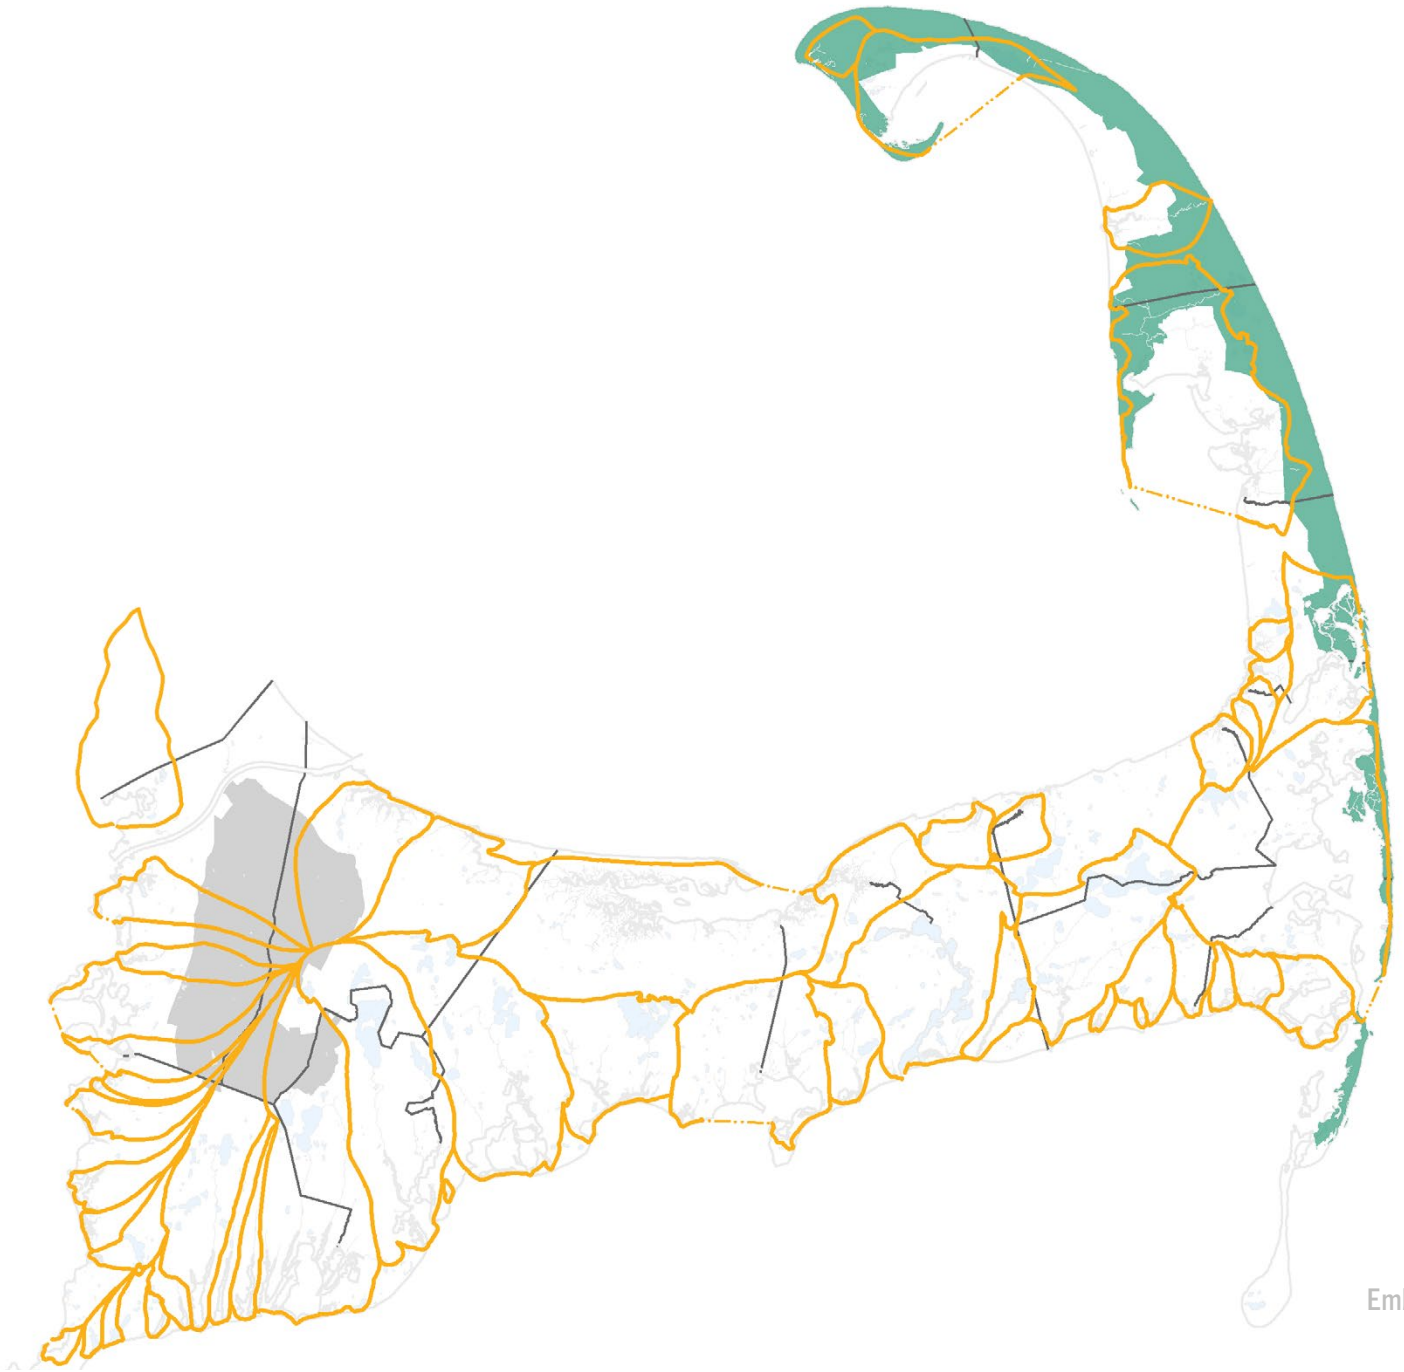
Watershed Based

Watersheds define the jurisdiction of the nitrogen problem.

A watershed is a geographic area separated from other regions by drainage divides within which all water flows to

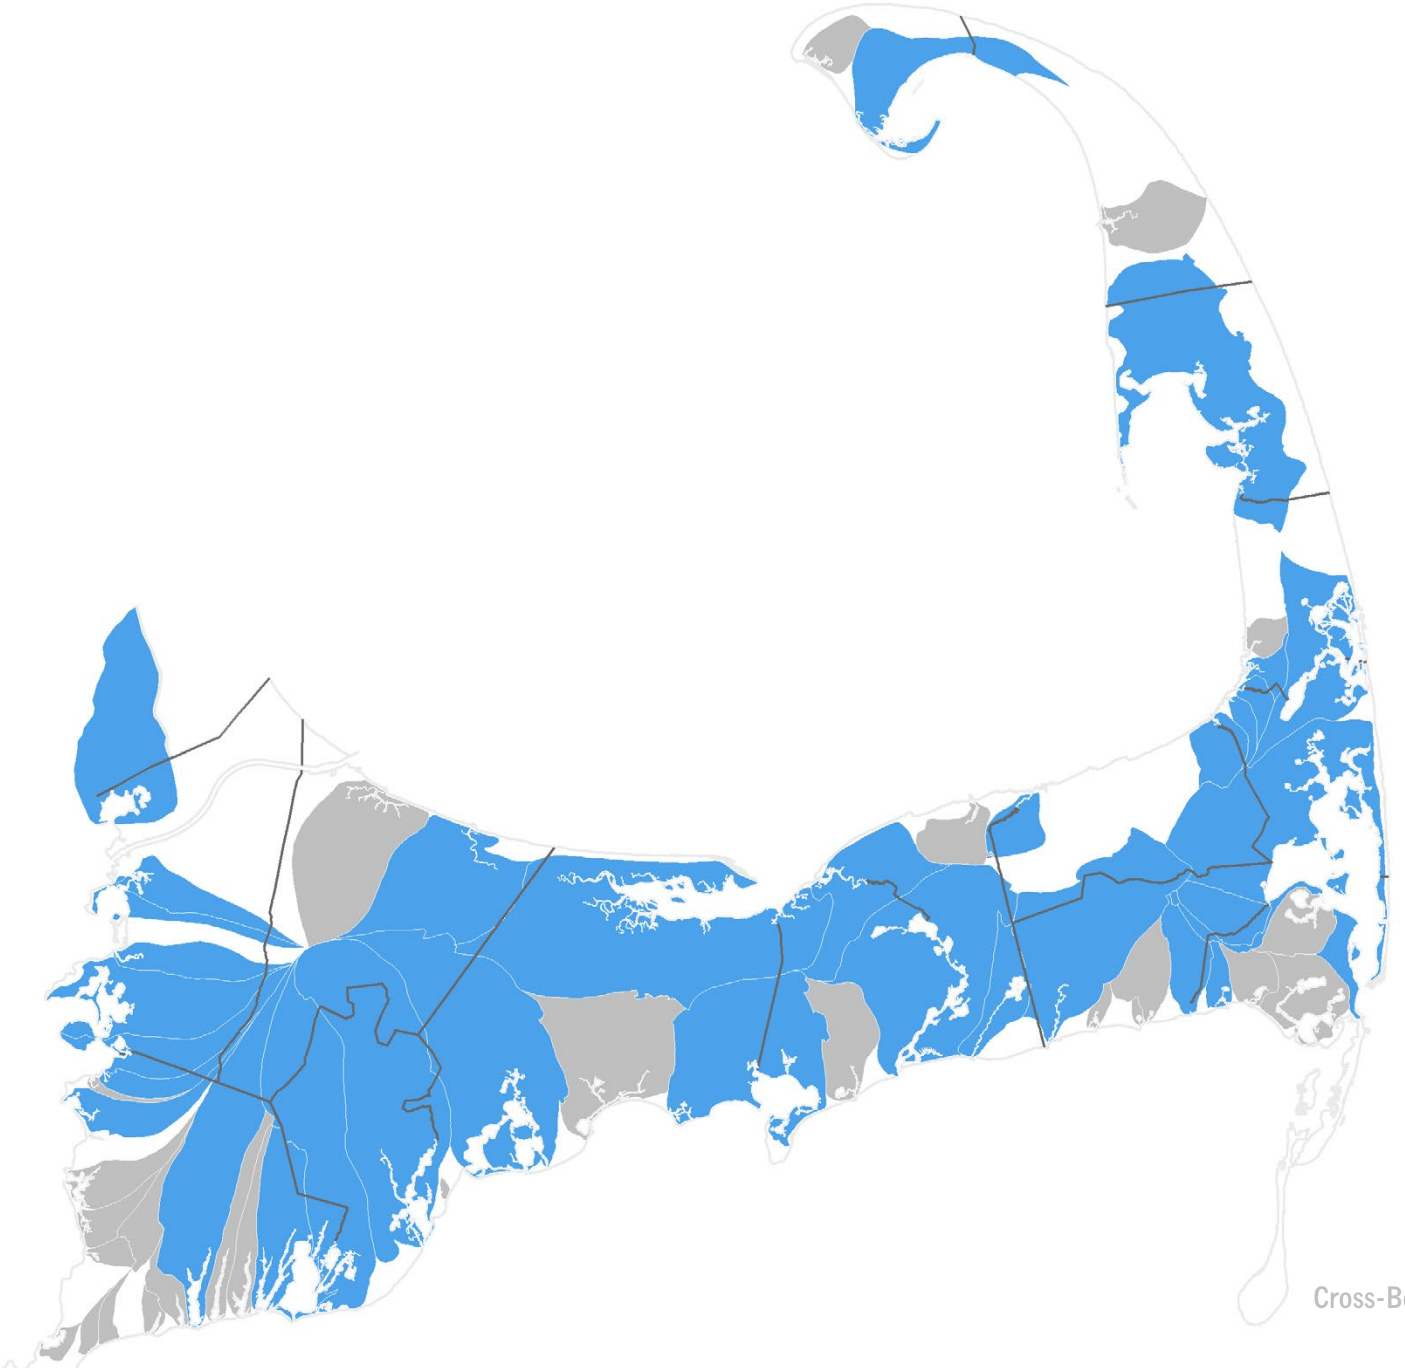
Decision Support Tool Data

WatershedMVP utilizes updated land use and water use data to inform wastewater load calculations, nitrogen load calculations and scenario planning. See **Appendix 5A** for more information on decision support tool data.



Embayment Watersheds

Figure 5-1



Cross-Boundary Watersheds

Figure 5-2

a common outlet, such as an embayment. There are 101 watersheds that flow to the surrounding marine waters of Cape Cod. Due to the highly-permeable nature of the Cape's geology, its watersheds are delineated based upon groundwater flow and water table maps. Fifty-three are watersheds to semi-enclosed coastal embayments (see **Figure 5-1**).

The remainder flow directly to Cape Cod Bay, Nantucket Sound, Buzzards Bay or the Atlantic Ocean. The coastal embayments are located at the margin of the aquifer and are the ultimate receiver of the aquifer's groundwater discharge. The south side embayments are more heavily impacted by nutrients and pollutants within the watershed, as they are shallower and receive less tidal flushing than water bodies on the north side.

Watersheds do not follow the municipal boundaries separating one town from another. Of the 53 watersheds to coastal embayments, 32 are shared by more than one town (see **Figure 5-2**).

Many of these watersheds have established total maximum daily loads (TMDLs). See Appendix 5B for details on each watershed, including characteristics, such as size and development, contributing towns, and TMDL status.

Comprehensive wastewater management plans (CWMPs) are a key step in addressing current and future wastewater needs in order to meet TMDLs; however, CWMPs are typically completed on a town-wide basis.

A watershed approach looks at the jurisdiction of the nitrogen problem – all of the contributing sources within a watershed and the receiving water, without regard to political boundaries. As discussed in Chapter 2, estuary water quality problems on Cape Cod have been negatively impacted by increased nitrogen generated by wastewater, fertilizer and stormwater runoff as a result of development that has outpaced infrastructure.

While watersheds define the jurisdiction of the problem, wastewater planning on Cape Cod has rarely been completed on a watershed basis. Communities have had difficulty implementing town-wide CWMPs that are perceived as too expensive and inflexible. The result often orphans necessary plans to address degraded water quality in individual watersheds . Communities shouldn't have to plan to the municipal jurisdiction. This regional water quality plan provides the background to support the design of local targeted watershed plans to result in faster, better and less expensive plans that yield higher rates of implementation.

Planning jurisdictions defined only by municipal boundaries will not necessarily meet TMDLs established for shared watersheds and often results in a plan so large and so expensive that it becomes difficult for a community to commit funding. A targeted watershed approach that does not require planning within the entire municipality, but instead, focuses on addressing the entirety of a watershed becomes more manageable and directly focused on the problem.

TARGETED WATERSHEDS

Designated Waste Treatment Management Agencies (WMAs) for those watersheds designated by this plan as nitrogen-sensitive are eligible for Targeted Watershed Management Plans (TWMPs).

Targeted watershed plans will qualify for expedited review and comprehensive permits with component reduction, remediation and restoration projects eligible for funding through existing and proposed resources identified in this Section 208 Plan Update, including the State Revolving Loan Fund.

TWMPs will include baseline water quality information and a nutrient management program (NMP) identifying watershed-based solutions to nitrogen over-loading of coastal waters.

TWMPs and CWMPs will be reviewed as Capital Developments of Regional Impact reviewed for consistency with this Section 208 Plan Update and the Cape Cod Commission Act.

A new approach supporting Targeted Watershed Management Plans (TWMPs), based on watershed boundaries, is recommended.

Recommendation R5.1:
Targeted Watershed Management Plan (TWMP) guidance including minimum performance standards for nitrogen in degraded water bodies shall be drafted and issued by the Cape Cod Commission, in concert with MassDEP, pursuant to this update within 90 days of its approval.

REGIONAL OPPORTUNITIES AND ECONOMIES OF SCALE

Working at the watershed level to develop local solutions makes the most sense from an environmental perspective; solutions should be identified within the jurisdiction of the problem. However, realizing potential savings from regional approaches may assist communities in implementing solutions. The following factors influence the cost of traditional infrastructure (Cape Cod Commission 2013):

- **EXTENT OF SEWERS:** Wastewater collection costs represent about 70% of the cost of constructing a system of sewers, treatment plants, and effluent disposal facilities. Costs can be reduced by focusing on the most densely developed areas, where the least amount of sewer pipe is needed to collect wastewater flows requiring nitrogen control. A cost advantage of the watershed-based approach is the assumed greater ability to find and serve these densely developed areas regardless of town boundaries. Watershed scenarios may be combined on a subregional level where densely developed areas cross watershed boundaries
- **GROWTH:** Growth in nitrogen-sensitive watersheds carries a heavy price. While only a portion of the existing nitrogen must be removed in these areas, all of the future nitrogen load must be mitigated. A 15% growth in wastewater flow translates to a potential 20% increase in capital cost. A 30% growth potentially increases the capital cost by 40%.
- **LOCATION OF EFFLUENT DISPOSAL SITES:** Even highly-treated effluent contains some nitrogen. If effluent is disposed of within nitrogen-sensitive watersheds as opposed to non-sensitive locations, more septic systems in that watershed must be eliminated or fitted with denitrification systems to meet the TMDL. If land availability within a town dictates that effluent must be disposed of in water supply recharge areas, then a higher level of treatment is needed at sharply increased costs for both capital facilities and for operations and maintenance (O&M). Looking regionally may increase the number of potential disposal sites in non-sensitive locations.
- **ECONOMIES OF SCALE:** Cost efficiency of wastewater treatment generally increases with flows treated. Significant cost savings can accrue if Cape Cod wastewater is treated at expanded existing public facilities, with selected new facilities, as needed, compared with a larger number of smaller facilities. Cost savings attributed to economies of treatment must be balanced with costs of conveying wastewater from collection areas and to disposal facilities.

With funding from Barnstable County, the Town of Orleans supplemented its CWMP with a focused study of the options available to share wastewater facilities with the towns of Eastham and Brewster. The details of this evaluation are presented in the December 2009 Wastewater Regionalization Study (Orleans-Brewster-Eastham) (Wright-Pierce 2009). Compared with each town building its own separate wastewater facilities, two-town and three-town regional solutions identified potential cost savings of 6% to 9% for capital costs and 18% to 25% for O&M costs.

Consideration of shared traditional infrastructure, as well as cooperative agreements to implement non-traditional technologies, should be given full consideration in order to limit the financial burden of water quality improvements to the community.

EXPANDED OPTIONS

SCENARIO PLANNING

Disagreement about technology solutions has resulted in polarizing local debates, sometimes discussed in terms of centralized versus de-centralized approaches or traditional solutions versus alternative solutions. One of the key distinctions depends on a considered option's reliance on a permanent physical connection of multiple sources to a collection system. The scenario-building approach

presented in this report used two contrasting approaches to solving Cape Cod's nitrogen problem, a traditional approach and a non-traditional approach, as an initial means to compare technologies and their effectiveness.

Watershed scenarios are a set of possible actions and interventions to meet nitrogen TMDLs and test the effectiveness of one or more combinations of potential solutions within a watershed. "Traditional" and "non-traditional" scenarios represent the limits of these two different approaches and define the parameters within which future scenarios can be developed. Two scenarios were developed for each watershed on Cape Cod and will be available through the Cape Cod Commission's Watershed Team technical assistance program discussed later in this chapter. The scenarios developed are NOT recommended, or preferred alternatives. Rather, the scenarios:

- Demonstrate the deployment of a wide spectrum of nutrient reduction technologies available to stakeholders when considering local options;
- Serve as an example of the Section 208 Plan Update recommended methodology to analyze both traditional and non-traditional technologies before making water quality management decisions;
- Provide a valid starting point for discussions about building local consensus for water quality management planning;
- Demonstrate the range and effectiveness of tools and methods developed by the Commission to assist stakeholders in creating conceptual level plans to support consensus building; and
- Define the possible scope of an Adaptive Management Plan.

Watershed scenarios were developed by two independent teams applying the following agreed upon conditions.

- Both teams used the same identified nitrogen targets (or the amount of nitrogen, in kilograms, that a water body can receive without exceeding the TMDL), as identified in the Massachusetts Estuaries Project (MEP) technical reports and TMDL reports for individual sub-embayments.
- Both teams attempted to solve the problem within the boundaries of the watershed.
- Both the traditional and non-traditional approaches utilized siting, performance, and cost information and data from the Technologies Matrix and the Barnstable County Cost Report and used WatershedMVP and the Watershed Tracker to make decisions about collection, treatment and technology siting.
- As a mutual point of reference, the traditional team evaluated a hypothetical analysis of an "all sewer" scenario and compared it to an "all innovative/alternative (I/A) septic system" scenario. Neither was necessarily a best choice for taxpayers or the environment, suggesting scenario approaches be targeted and mixed.

Traditional Scenarios

Traditional scenarios include centralized, satellite and cluster collection and treatment technologies and maintain as many homes and businesses on Title 5 septic systems as possible. This approach provides a reliable and predictable level of nitrogen source reduction with a known cost structure. Less advantageous considerations of traditional scenarios are the high cost of constructing collection systems in low-density residential areas inability to address nutrients already in the ground water.

Non-Traditional Scenarios

Non-traditional scenarios include use of other technologies and approaches as outlined in the Technologies Matrix. Many non-traditional technologies will intercept and remediate nutrient laden groundwater, resulting in the potential for faster water quality improvement. Non-traditional technologies that intercept groundwater remediate nutrients from stormwater and fertilizers,in addition to wastewater. However, many non-traditional technologies vary widely in performance and cost. They also don't reduce the source load and can be more difficult to permit. See Chapter 4 for a more detailed discussion of benefits and drawbacks of each technology identified in the Technologies Matrix.

TRADITIONAL AND NON-TRADITIONAL SCENARIO DEVELOPMENT

TRADITIONAL APPROACH

The traditional approach considered the greatest controllable source of nitrogen (wastewater) as a percentage of the whole, identified the most efficient groupings of wastewater sources in each watershed, and suggested collection and treatment options. In developing the traditional scenarios, the present watershed nitrogen loads and the amount of necessary reductions to meet the TMDL were determined.

NON-TRADITIONAL APPROACH

The non-traditional approach started with the premise that collection systems should be avoided or minimized to the greatest extent possible. Although conventional wisdom and practice suggests that economies of scale in the construction of wastewater treatment facilities result in the least expensive and most effective treatment, there is valid concern that the case studies supporting this view are from more urban communities with existing but degraded infrastructure. Cape Cod is missing both of these qualifications, having neither the urban density characteristics nor the existing infrastructure. Cape Cod has less than 4% of the population of the state and approximately 20% of the septic systems. Only 3% of the parcels and 15% of the wastewater flows on Cape Cod are centralized.

The Cape also has an attribute not shared by other communities - its seasonal second homeowner economy. The population of Cape Cod increases from 216,000 year-round residents to nearly 650,000 or more on any given day between Memorial Day and Labor Day, hosting an average of 7.2 million people in that four-month period. Wastewater treatment facilities designed for the four weeks of potential peak flow would have a much larger capacity than needed 48 of 52 weeks a year.

Additionally, there are people in every community advocating for wastewater solutions that rely less on structural interventions, which may be less sustainable over time, than strategies that favor the modification of natural systems. The technologies and strategies prioritized in the non-traditional approach also tend to result in less movement of water between watersheds and put a greater emphasis on comprehensive system restoration or improvement.

The non-traditional team began with the same nitrogen removal target as the traditional team and began by assigning nitrogen reduction credits to the watershed for fertilizer reductions and stormwater management. The team then considered an array of watershed and in-embayment options, as detailed in the Technologies Matrix, consisting of a broad range of innovative nitrogen management strategies to intercept and treat nitrogen in the groundwater or to assimilate and treat it in the receiving waters. Watershed practices include permeable reactive barriers (PRBs), constructed wetlands, phytoremediation and fertigation wells, among others. Sites were located using the Cape-wide site screening analysis for non-traditional technologies described in Chapter 4. Embayment practices include, but are not limited to, shellfish bed restoration, aquaculture, floating wetlands, dredging and inlet modifications.

Stormwater and fertilizer constitute approximately 20% of the nitrogen load across Cape Cod and in some areas a higher percentage. The non-traditional team estimated watershed stormwater and fertilizer loads and applied a 25% reduction credit to those loads based on the adoption of management programs. Adoption of policies and development of capital projects are both recommended to achieve these levels of reduction.

For stormwater projects, certain reductions can be assumed based on site specific conditions and methods employed. Direct and untreated stormwater discharges are no longer allowed under the Massachusetts Department of Environmental Protection (MassDEP) Massachusetts Stormwater Standards and are being mitigated using a range of stormwater retrofit projects including infiltration, bioretention, vegetated swales and other low impact development (LID) practices. These retrofits will also contribute toward compliance with the emerging United States Environmental Protection Agency (US EPA) Municipal Stormwater Separate Storm Sewers (MS4) Program (discussed in Chapter 3) which will require regulated communities to address water quality impairments.

Significant efforts and accomplishments to reduce fertilizer impacts are also being instituted on Cape Cod. These include a successful program developed and instituted by the Cape Cod Golf Course Association to

reduce fertilized areas and rates that havs resulted in a reduction of approximately 50% of the applications. Similarly, a District of Critical Planning Concern (DCPC), adopted by the Cape Cod Commission in 2014, enables towns to develop regulatory programs to more carefully manage fertilizer applications, thereby reducing the rate of fertilizers leaching into the groundwater. Monitoring to prove that anticipated nutrient reductions are achieved will be required and reductions should be considered as part of the watershed adaptive management plan.

The next step in the non-traditional approach considered alternative on-site options that have been screened for geographic suitability. A number of alternative wastewater source controls were evaluated in this step. Ecotoilets are alternative toilets that target the source within the building. These include urine diversion (UD), composting, incinerating and packaging toilets where the waste materials are collected and temporarily stored before processing. These technologies allow little or no human waste to enter the septic system (only gray water from the shower, laundry and sinks). Social acceptability and significant, but improving, regulatory impediments had the team using these strategies in a targeted way (schools, for example).

The non-traditional approach produced a targeted starting point for consideration as part of an adaptive management program in most watersheds.

Together, the traditional and non-traditional approaches provide the tools and parameters around which towns within a watershed can develop locally-preferred options to meet TMDLs.

Development of these two approaches led to another distinction between technology options. Technologies and approaches can be grouped in to three categories: policy, collection, and non-collection. The primary difference between the categories lies in the need for a collection system, which is largely defined as a system for removing waste from the property, and in many cases is the most expensive component of a strategy. Locally developed plans should design watershed scenarios with an appropriate mix of technologies using a hybrid planning approach, which should be used as the basis for a NMP as part of a TWMP.

In order for expanded options to be permitted there has to be a sustainable and robust monitoring program.

TARGETED WATERSHED MANAGEMENT PLANNING - HYBRID WATERSHED APPROACH

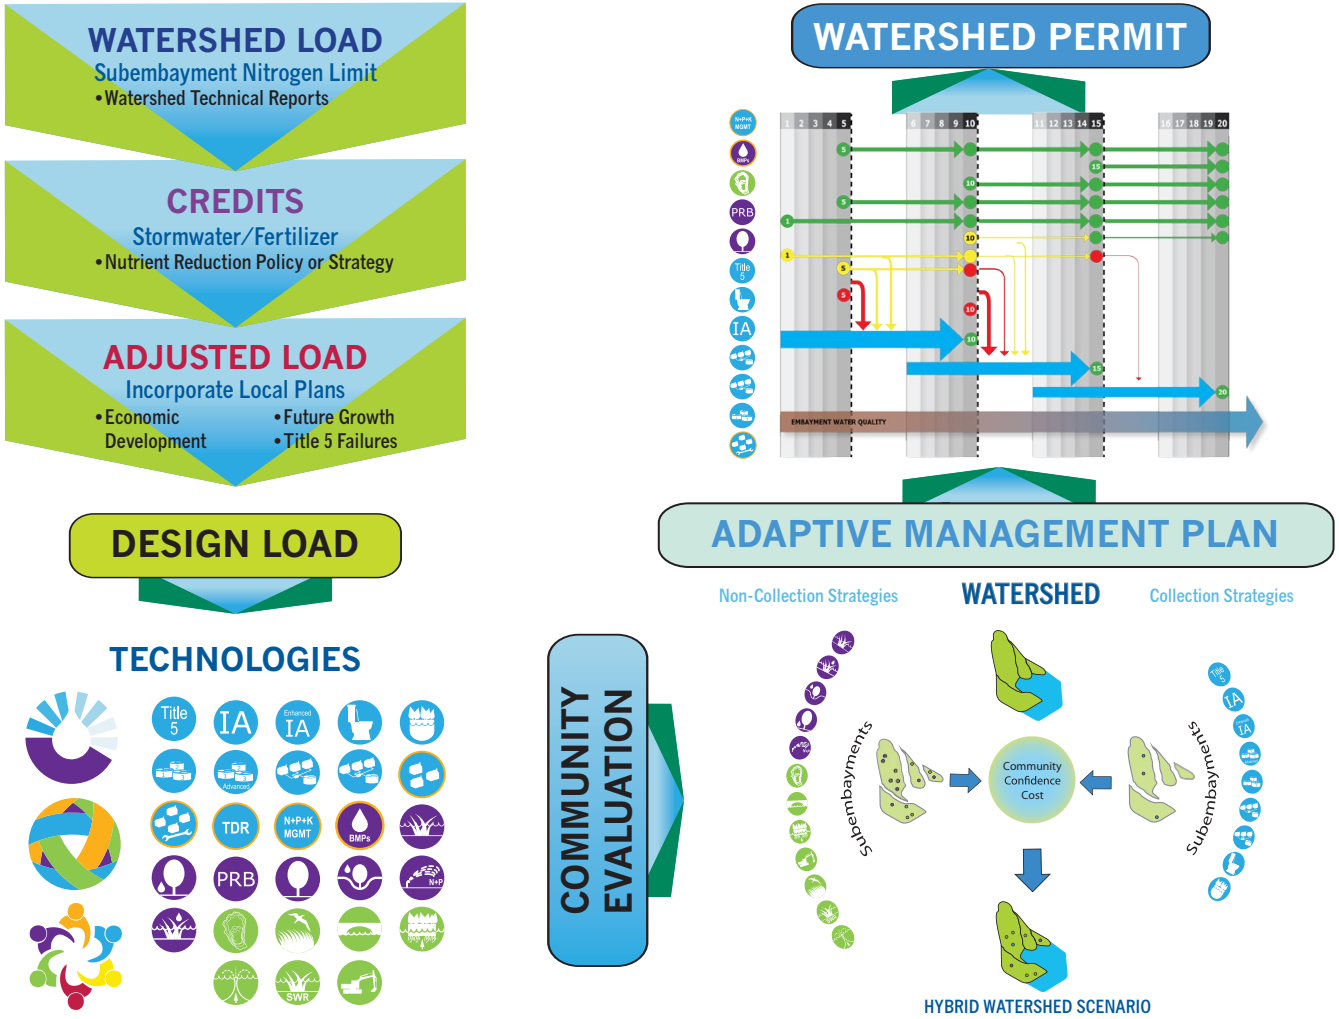
The technical review detailed above grouped technologies as “traditional” or “non-traditional.” That nomenclature was specifically defined for that purpose but its continued use may unnecessarily bias future planning and regulatory efforts. In the recommended adaptive planning format the contrasting approaches are referred to as collection management and non-collection management of nitrogen.

The recommended process encourages the establishment of an agreed watershed target for nitrogen reduction and then adjusts those targets by incorporating credits for nitrogen-reducing policies and any other nitrogen impacts of local plans. Structuring contrasting approaches to meet water quality standards sets the parameters for the public discussion. A subembayment consideration of a collection scenario and a non-collection scenario with the assistance of Cape Cod Commission decision support tools will allow local decision makers to move beyond “engineering” discussions and instead focus on issue of community, cost and confidence in identifying the most efficient and effective nitrogen management plan.

This planning process begins with identified nitrogen reduction targets and then sequentially and cumulatively reduces the load to achieve those targets. Depending on the embayment impacted, this process may be most effectively done on a subembayment scale (see **Figure 5-3**).

- **IDENTIFY TARGET REDUCTIONS AND GOALS:** To determine the level of intervention necessary to restore water quality in each embayment, nitrogen reduction goals are established for each watershed. Where MEP reports have been prepared or TMDLs established the values identified are utilized. For those watersheds where these studies have not yet been completed interim targets could be utilized. A 25% reduction of existing nitrogen is assumed as a placeholder for those watersheds without MEP reports and established targets. The reduction goals

Targeted Watershed Planning



Targeted Watershed Planning

Figure 5-3

are calculated as the difference between the existing load and the target load (**reduction required (kg)= existing load – target load**).

- **ESTABLISH DESIGN LOAD:** Cape Cod towns are actively targeting stormwater and fertilizer nitrogen, among other preventative measures, and developing mitigation projects/programs to reduce their loads. These efforts should be taken as a credit towards achieving the required nitrogen reductions. Aside from water quality restoration in coastal embayments there are a number of reasons a community may want or need to provide infrastructure within a watershed. Areas that cannot comply with Title 5, due to depth to groundwater, poor soils, inadequate setbacks or lot areas, among other reasons, need new infrastructure solutions. Communities may have identified growth areas, such as village centers and growth incentive zones, where high density is anticipated. Or pond recharge areas may be significant in the watershed. A design load is the total nitrogen load to be removed after accounting for other needs of the community and is calculated as the difference between the reduction required and the credits, with the addition of the non-nitrogen community needs (**design load (kg) = reduction required (kg) – credits + non-nitrogen community needs**).
- **NON-COLLECTION MANAGEMENT OPTIONS:** A broad range of innovative and non-traditional nutrient management options evaluated as part of the non-traditional scenario to intercept and treat nutrients along their flow paths through the watershed or to assimilate and treat them in the receiving waters (embayments) should be considered.
- **COLLECTION MANAGEMENT OPTIONS:** Alternative on-site wastewater source controls, such as ecotoilets and I/A systems, should be considered first in areas where a lack of housing density coupled with a need for nitrogen reduction are present. If the cumulative nitrogen reductions following the use of these source controls and the non-collection options have not achieved the required reduction then collection and treatment in these areas may be necessary.

This iterative process of comparing technologies based on available sites, cost efficiency and performance in a phased manner with community input allows consideration of "right-sized" infrastructure. It is recommended that targeted watershed planning efforts adopt this hybrid approach.

> **Recommendation S5.2:**
> **Targeted watershed planning efforts shall adopt a hybrid watershed scenario planning process.**

MONITORING

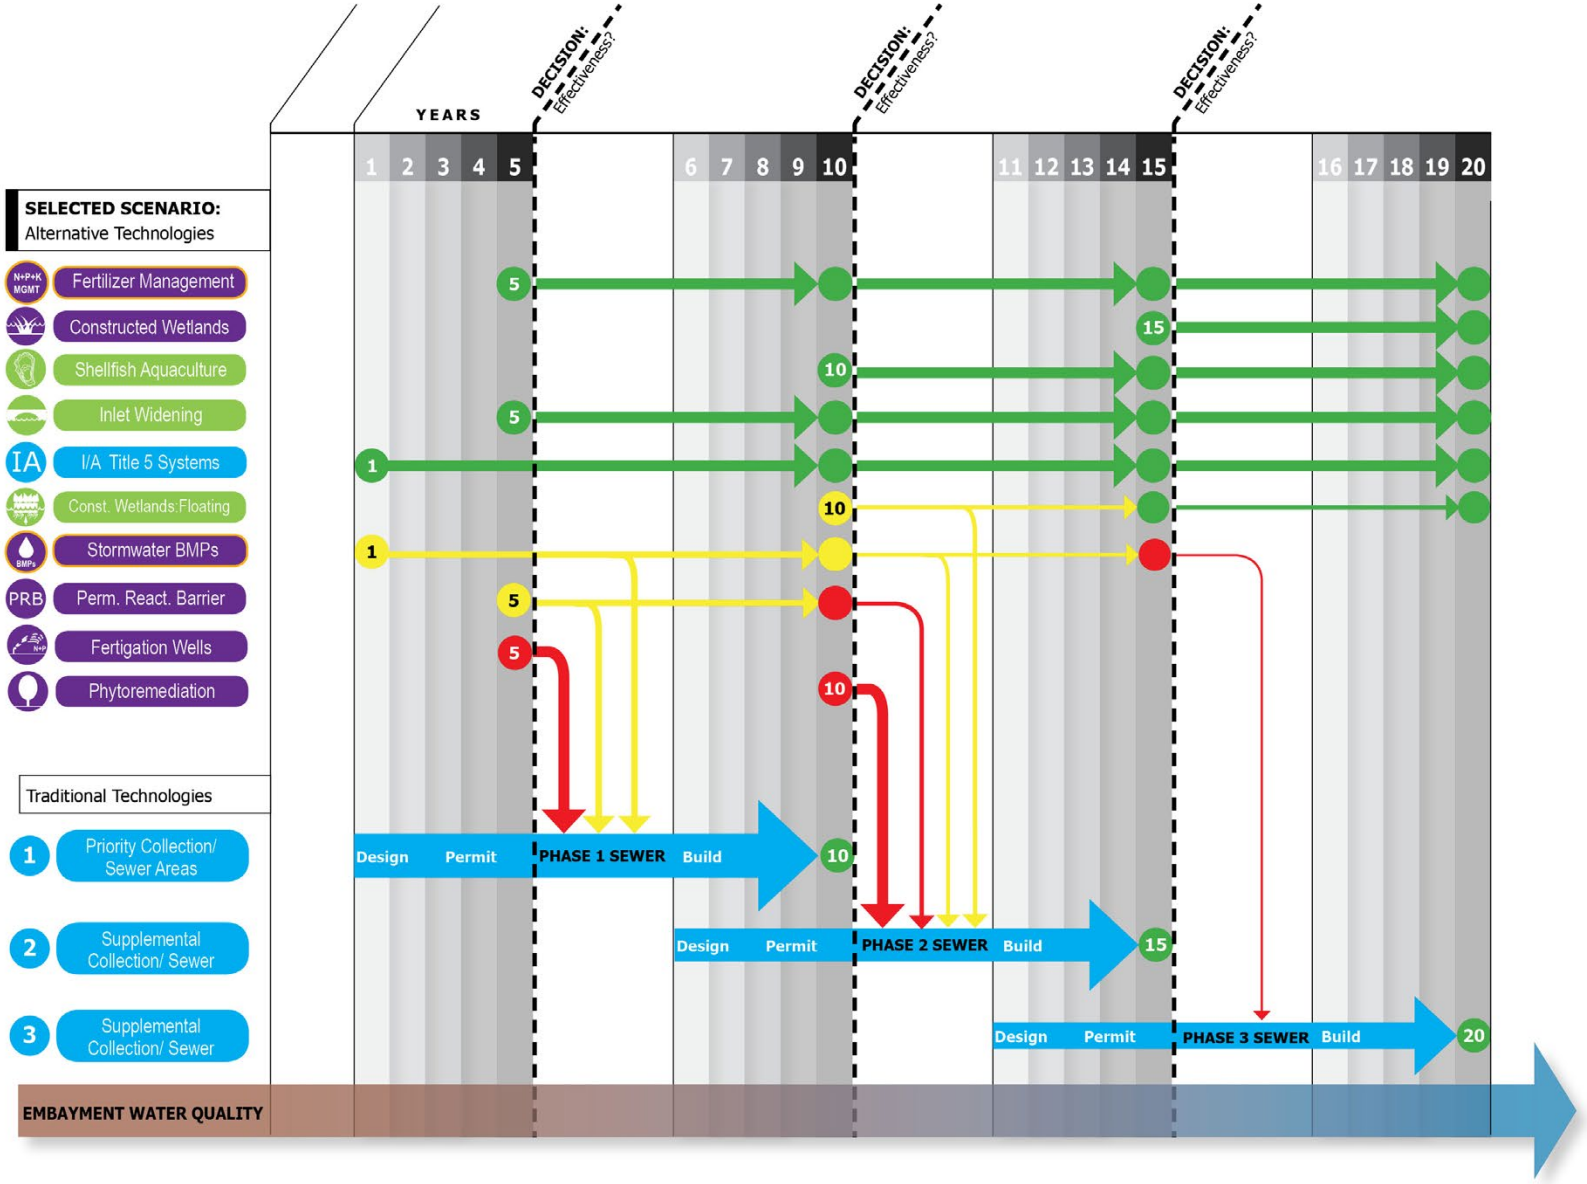
Monitoring is crucial to measure progress toward meeting water quality goals; it will provide baseline metrics for evaluating technology performance (pilot testing), TMDL compliance of the implemented solution, and adaptation of the hybrid plan to optimize TMDL compliance. Both performance monitoring and water quality monitoring will be necessary to determine success of individual technologies and changes in water quality. See Chapter 4 for more detailed information on monitoring.

ADAPTIVE MANAGEMENT

Adaptive management provides a framework to move forward efficiently with practices that can generate short-term results, and allow for adjustments to optimize the plan over the implementation period (see **Figure 5-4**). The proposed adaptive management framework enables a thorough vetting of new technologies while maintaining a secure foundation of proven traditional technologies. The plan provides a thoughtful process for integrating emerging and non-traditional technologies with traditional practices concurrently in watershed plans.

Applying this approach, each TWMP that is developed will have an adaptive management plan to condition its approval, with specific milestones and reporting.

Each TWMP will include a set of traditional and non-traditional practices assembled to meet identified nutrient reduction targets and desired water quality goals. Traditional technologies may best serve densely developed town centers, while non-traditional technologies may be applied in water bodies for short term water quality improvements. The adaptive management process provides a means to optimize this combination of technologies.



Adaptive Management Framework

Figure 5-4

In some watersheds a traditional sewering plan may be identified for construction during the first phase of implementation. Future expansion, or phases, of this core collection system will be part of the initial wastewater management planning, and will serve as the backup plan for future phases of the watershed plan in the event that the non-traditional practices do not perform adequately.

As discussed in Chapter 4, piloting some of the alternative technologies that show particular promise for remediating Cape Cod water quality problems is needed to establish performance of these technologies. In cases where pilots suggest that a technology will not perform as hoped, the adaptive management plan will identify a back-up strategy using more certain approaches that will lead to water quality improvement.

This adaptive management framework is structured in five year increments. This timeframe enables two years for the design, permitting and construction of technologies along with a minimum three year testing period. At the completion of each five year period, an evaluation of the performance of deployed technologies takes place. These assessments will include the achieved nutrient removal performance, cost effectiveness, and any associated co-benefits.

Technologies that meet the identified objectives can continue to be used and additional installations may be implemented in the watershed. In instances where partial success is realized, an evaluation of possible adjustments and improvements takes place and, if deemed appropriate, continued application of that technology may occur. Where poor performance is realized, further application of that technology will be discontinued or modified within that watershed.

Essential to the successful implementation of a TWMP is comprehensive monitoring of water quality within sensitive water bodies. Overall water quality improvements at the established MEP sentinel stations will need to be evaluated. This information will be integrated with the technology performance to determine next steps in the implementation of the watershed plan.

In recognition of the complexity associated with implementing a monitoring and adaptive management plan, the following components are recommended for inclusion and should be incorporated into Commission and MassDEP approvals and permits. These components include but are not limited to:

- Establishment of a technical review panel to meet regularly and comprised of local, regional and state representatives
- Pilot project design, development and monitoring
- Targeted watershed project funding, design, construction, and permit compliance
- Compliance monitoring including baseline water quality and habitat monitoring for estuaries

EMPOWER COMMUNITIES

Community Engagement is more than a box to check when developing a plan. Taking it seriously means making complex data sets easier for citizens to understand and use in local decision-making.

WATERSHED TEAMS

Municipalities are encouraged to consult with the Commission to ensure coordination between active watershed planning efforts and the Section 208 Plan Update and to establish consistency between proposed municipal plans and the Section 208 Plan Update with respect to the evaluation of wastewater needs, watershed management alternatives and alternatives analyses. The Commission will assign a Watershed Team to the specific planning efforts to assist with the decision support tools, permitting of technologies and financing.

Recommendation S5.3: The Cape Cod Commission shall assign Watershed Teams to provide technical assistance to Waste Treatment Management Agencies (WMAs) and municipalities.

COMPOSITION

Watershed teams may include experts in water resources, GIS, land use and economic development planning, finance modeling, legal/regulatory, technologies, and facilitation.

Water resources experts include hydrologists and engineers with extensive experience in Cape Cod's unique hydrogeology and water quality challenges. They can assist in developing targeted watershed plans by applying Watershed MVP and the Watershed Tracker, and can evaluate site-specific nutrient mitigation projects using groundwater modeling, and nutrient loading and mitigation assessments.

GIS analysts have direct access to the most current databases and are directly involved in the continual development and updating of GIS-based analytical programs such as Watershed MVP. They can provide screening for potential nutrient management sites, apply a GIS technology viewer that is designed to track and illustrate watershed management scenarios, and can optimize collection areas based upon an integrated density-frontage-proximity algorithm.

Land use planners are involved in updates to the Regional Policy Plan (RPP), local comprehensive plans, establishment of Critical Planning Areas of Concern, and conduct Regional Economic Strategy Executive Team (RESET) projects. They can advise on consistency of watershed plans with the RPP, buildout scenarios and related land use issues.

Legal and regulatory experts work closely with MassDEP and US EPA regulatory staff and are very familiar with the Section 208 consistency requirements. They can provide assistance with permitting, Massachusetts Environmental Policy Act (MEPA) compliance, regional arrangements, and the development and implementation of an adaptive management plan.

Non-traditional technology experts are directly involved in the state-of-the-art research (including performance and costs) on a broad range of green infrastructure and non-traditional technologies. They can provide assistance in selecting, siting, evaluating non-traditional/green infrastructure technologies, and in the application of Technologies Matrix and Watershed Calculator.

Facilitators have served a critical role in the successful development of the Section 208 Plan Update. They can assist the WMA with consensus building, public engagement and outreach and overall project management.

ROLE

The role of the Watershed Team is to provide assistance to communities in developing an effective local watershed restoration and management plan in compliance with the Section 208 Plan Update. The Watershed Team will work with towns, identified stakeholders and third-party consultants to develop an integrated hybrid plan that addresses identified water quality restoration goals and incorporates local preferences. Specifically, the Watershed Team can assist in developing a step-by-step approach to building a locally-supported watershed strategy. Specific tasks that the Watershed Team can assist with include:

- Developing a watershed plan outline, tasks and schedule including a consensus-building process and a public engagement strategy
- Developing a scope of services for a third-party contractor to provide specific engineering tasks necessary to compliment the Watershed Team
- Presenting Section 208 watershed plans to identify a range of options potentially-available to address the nutrient reduction goals
- Explaining and applying analytical tools including Watershed MVP, the Watershed Tracker, the Technologies Matrix and the Watershed Calculator
- Assisting in the development of a hybrid plan by providing recommendations for green infrastructure/non-traditional practices and traditional sewer collection systems
- Working with the WMA, stakeholders and third-party contractor to evaluate the feasibility of individual Hybrid Plan components using site-specific data and local knowledge
- Identifying and evaluating potential public/private options such as satellite wastewater treatment systems
- Working with the third-party contractor in developing comparative cost information

- Assisting in the development of permitting strategies
- Developing targeted monitoring plan and associated adaptive management

BENEFITS

Utilizing a Watershed Team positions a community to align their watershed planning efforts with the Section 208 Plan Update early in the process. There should be benefits to this approach. Benefits to a community utilizing this resource fall in to three categories:

- Technical Assistance
- Regulatory Flexibility
- Financial Resources

The Watershed Team provides interdisciplinary, watershed specific technical assistance, creating a clear path toward consistency with the Section 208 Plan Update. With consistent communication with a Watershed Team from the outset, communities should be able to bypass some of the regulatory review that would otherwise be required. As described in Chapter 3, it is recommended that the 2015 Update to the Regional Policy Plan (RPP) include a consideration for Capital Developments of Regional Impact (CDRIs), which would exempt capital planning projects, such as TWMPs, that have been deemed consistent with another regional plan from DRI review. Consistency with the Section 208 Plan Update and a CDRI certificate should allow communities access to new sources of revenue that are made available to the region (see Chapter 6 for a more detailed discussion on revenue).

Recommendation C5.4: Local targeted watershed management plans consistent with the Section 208 Plan Update should qualify for existing and potential revenue sources.

WATER RESOURCE CENTER

With decision making, project sponsorship and operations based at the local level, there remain certain activities and functions that, managed regionally, would benefit municipal operations, attract resources and lower costs to residents. Four specific functions: financing, monitoring, scenario analysis and septic management would all become cheaper and more beneficial in a regional service center than if left to the individual communities.

Enhanced or new authority would be needed to establish the capability to operationalize these services, but the descriptions below provide a brief synopsis of their potential:

1. Financing: A regionally-based financing capability would offer towns the option to seek financing from a regional entity rather than extend the town's full faith a credit as is currently required. A regional financing entity could be eligible for State Revolving Fund (SRF) loans and also attract additional funds to increase community access to additional subsidy. Financing through such an entity would preserve the town's full faith and credit for use in other municipal projects and would enable towns to proceed with projects based upon majority action by the voters of each respective community.
2. Monitoring: Adaptive management, as envisioned in this plan, relies on a robust program of water quality monitoring both pre and post implementation. The procurement of sentinel station monitoring of all embayments and near shore stations will lower the overall cost of monitoring while also relieving towns of a major and ongoing expense. An additional benefit of a unified approach to monitoring is the ability to ensure easy and consistent availability of monitoring results to the communities and the general public.
3. Scenario Analysis: As a part of the Section 208 Plan Update process the Commission has developed leading edge capabilities to analyze the outcomes and water quality implications of differing nitrogen management scenarios. The ability of communities to assess the costs and benefits of different alternatives will enhance local decision making and provide a low/no cost capability that would otherwise have to be procured by towns at great local expense.
4. Septic Management: Integral to the cost control strategy of this plan is the retention of as many existing septic systems as possible. Extending the useful life of septic systems to be retained will both lower and spread out the costs associated with system replacement. The scheduled pumping and maintenance of systems will also allow for the

optimization of the use of septage treatment. The current system relies exclusively on homeowners to properly maintain systems and also leaves them at risk of the high cost of replacement should a system abruptly fail.

The institution of a regionally-based program that would ensure proper pump out and maintenance as well as providing replacement services would have the multiple benefits of extending the life of existing systems, controlling the flow of septage to treatment plants and protect homeowners from exposure to financial hardship associated with system failure. Such a system could be established based upon an annual septic fee that would cover the cost of pump out as well as replacement.

06 MONEY

Cost & Financial Affordability

A primary goal of this plan is to lower the cost of meeting water quality standards and spread the remaining costs equitably among all who enjoy and benefit from Cape Cod. In a region that has largely deferred and avoided the cost of necessary wastewater management, residents are appropriately sensitive to costs. The high cost of traditional approaches has been a major impediment to wastewater planning and implementation on Cape Cod.

Of particular concern to the region is its large seasonal fluctuation in population and wastewater flows. The need to accommodate the large flows experienced over a brief four week period – the last two weeks of July and first two weeks of August – creates an additional burden on the smaller year-round population.

MONEY

Chapter 6: Cost & Financial Affordability

The Cape Cod Economy

The Cape Cod economy is heavily seasonal with more than one third of its gross regional product (GRP) coming from tourism-related industries. With the arrival of second home owners and summer tourists, the population more than doubles at any given time in July and August. The region's infrastructure, including wastewater infrastructure, must be scaled to handle this population peak of approximately 650,000 people.

The GRP for Cape Cod hovers between $7 and $7.5 billion a year (between 1.5% and 2% of the gross state product). Significant portions of the GRP come from retail trade, real estate and rental activities, and accommodation and food service. Wages in these industries are generally low, and wages in Barnstable County lag behind the state and the nation. Moreover, Barnstable County is below the state median income, at $60,685, and wages have not grown in real terms since 1990.

The current (2014) equalized evaluation of property values for property tax purposes on Cape Cod is $77.8 billion for all 15 towns combined. The total property taxes collected (the levy) in 2014 was $615 million with an average single family tax bill of about $4,000 a year. In comparison, the average annual single family tax bill in Massachusetts is nearly $5,000.

A recent study by the Cape Cod Commission on the Three Bays watershed in Barnstable showed that a decline in water quality results in lower property values (http://www.capecodcommission.org/3bays/). Given the way property tax works, a reduction in coastal property values due to poor water quality will shift the tax burden to those with property away from the water and less able to absorb increased taxes not associated with any water quality improvement.

Image on Facing Page: Topics addressed in this chapter can be grouped in to four categories – the total cost of the solution, how to finance solution, how to pay for the solution, and how to address the financial impact on individual households.

Estimated Cost and Affordability

Just as Cape Cod's watersheds have a finite capacity to absorb nitrogen, the Cape's property owners have finite financial resources to implement solutions to address water quality impairments. The estimates for solving the Cape-wide problem through traditional centralized treatment, whether working town-by-town or watershed-by-watershed, range from $4.2 to $6.2 billion (Cape Cod Commission 2013). If paid through property tax betterments and user fees, the cost of such a traditional approach exceeds the United States Environmental Protection Agency (US EPA) affordability standard of 2% of median income being allocated to wastewater solutions. It's also important to note that the 2013 median income for Massachusetts is $62,963, leaving Cape Cod residents (median household income is $60,685), on average, less able to afford necessary wastewater infrastructure than other state residents.

Property owners on Cape Cod will not bear the burden equally, although most contribute to the problem and all

will benefit from its resolution. Much will depend on how the solutions are financed and what sources of funding can be employed. The challenge is to equitably and fairly spread costs among all who enjoy Cape Cod, from the year-round resident to the second homeowner to the tourist visiting for a week or a day. Just as this plan has advocated considering a variety of water quality solutions, it encourages consideration of many different revenue sources available at the federal, state, regional and local levels. A goal of the Section 208 Plan Update is to reach a common understanding that the burden of funding needs to be shared by everyone who benefits from a healthy Cape Cod environment.

This plan strongly encourages collaboration among towns to address the nutrient problem in the shared watersheds across the Cape. Conservative estimates from the Regional Wastewater Management Plan suggest that shared infrastructure and economies of scale could result in a savings of up to 9% on capital/construction costs and up to 25% on annual operations and maintenance costs (Cape Cod Commission 2013). This plan also encourages collaboration at the local, regional and state level to implement land use policies that focus future growth in those areas where wastewater treatment exists or can be constructed for the lowest cost and serve the greatest number.

Watershed Plan Cost Categories

PLANNING & DESIGN COSTS

Planning and design costs are incurred prior to any construction. Towns may access funds from the State Revolving Loan Fund (SRF) to support wastewater or watershed planning but much of the design must be covered using local funding sources.

CAPITAL COSTS

Capital costs are those incurred in the construction of any type of treatment system, including traditional collection and treatment technologies and non-traditional technologies, such as permeable reactive barriers or constructed wetlands. Capital costs are generally financed through borrowing, although some limited grant opportunities exist to lower the amount to be financed.

OPERATION AND MAINTENANCE COSTS

Operation and Maintenance (O&M) costs are the annual recurring costs of nutrient interventions, including nontraditional technologies, and keeping them in working order. O&M is generally paid for through fees or tax revenues as costs accrue. These costs are generally not financed using loan or bonding programs. O&M costs will vary greatly by technology solution and are estimated on a technology-by-technology basis in the Section 208 Plan Update Water Quality Technologies Matrix (Technologies Matrix), discussed in Chapter 4.

MONITORING COSTS

Monitoring is an essential component of adaptive management. Monitoring will assess the effectiveness of the different technologies at removing nutrients from the watershed. The results of monitoring will indicate which technologies are working and which are less successful. Permitted discharges are always required to undertake discharge monitoring and new technologies being piloted will also be required to monitor to determine actual performance.

In addition to monitoring of individual systems or management measures, baseline water quality will also be monitored to understand how marine systems are responding to the suite of management measures being implemented. The cost of this monitoring is significant, but small when compared to the potential savings in investment in unnecessary management measures should monitoring not have undertaken. Monitoring costs are typically considered an operating expense and paid for as they are incurred.

One way to manage costs is to consolidate the monitoring of sentinel stations around Cape Cod. Both the Section 208 Plan Update Technologies Panel and Monitoring Committee identified the need to establish a process and structure

for reporting and maintaining data in a consistent and centralized location as two major issues associated with monitoring and compliance.

Mandating monitoring at the town level puts a financial burden on towns that, in some cases, may make implementation infeasible. In addition, monitoring at the local level allows for inconsistencies in sample collection, analysis and distribution.

The appropriate scale for monitoring and maintaining monitoring data is at the regional scale. The Commission's Strategic Information Office (SIO) currently maintains an expansive data warehouse, and the Commission's Watershed Management Program maintains a regional historic warehouse of water resources information on behalf of Barnstable County and the 15 towns. Data hosting and maintenance would be available for a robust monitoring program providing consistent and accurate data feedback loops among the towns and appropriate agencies. Chapter 4 recommends that Barnstable County assume responsibility for monitoring and maintaining regionally consistent data sets that are freely accessible to the public. Maintaining data in a centralized, accessible location will allow information to transfer from one project to another, and assist the region in prioritizing projects based on water quality improvements and/or further degradation. In addition, designating a single responsible party for monitoring will allow for efficiencies and economies of scale in purchasing equipment and managing data. The program should be developed in conjunction with the Massachusetts Department of Environmental Protection (MassDEP) to ensure consistency in water quality assessments.

There is currently an effort underway by the Cape Cod Water Protection Collaborative to coordinate local sampling with an appropriate regionally procured laboratory(ies) for analysis. The Collaborative is seeking state matching funds to allow for a single procurement to provide ambient water quality sampling at the base stations all around Cape Cod. Data hosting and data accessibility should be through the SIO at the Cape Cod Commission. Regional technical assistance to provide data interpretation, assistance and outreach on watershed assessments and monitoring programs for Total Maximum Daily Load (TMDL) compliance and performance monitoring would provide communities with necessary information to move forward with their adaptive management plans.

Financing a Watershed Plan

Municipal finance limits the options available to communities looking to finance wastewater implementation. The vast majority of municipal revenue comes from two sources – local property tax assessments and state aid. Property tax collection operates under the constraints of Proposition 2 ½ – a voter-adopted law that limits the ability of a town to increase taxes beyond 2.5% annually without specific voter approval. This represents a barrier that has acted as a brake on municipal spending, especially on large capital projects. State aid is a critical piece of the municipal revenue picture but is subject to the vagaries of the state budget process and is based on a formula heavily weighted on property valuation, a disadvantageous approach for Cape Cod and other coastal communities.

Levy collections can increase above the legal limit specified by Proposition 2 ½ one of two ways. Voters may elect to override the limit by an amount in excess of 2.5% through a ballot question. An override provides a permanent and lasting increase in the amount of money a town may raise in property taxes and is a non-specific increase that can be expended on any municipal function. Debt exclusion allows for a temporary increase in tax collections that is earmarked to pay off the debt associated with the bonding of a specific capital expenditure. The tax increase expires once the bond payments associated with the project are paid off. The use of debt exclusions is most commonly associated with large capital projects, such as those associated with wastewater. Debt exclusion typically requires two steps, a local town meeting or town council vote, by a 2/3 majority, to authorize a borrowing and then a town-wide simple majority ballot question on the debt exclusion question. Some towns have room within their municipal levy limit to borrow inside the constraints of Proposition 2 ½ and do not need to obtain voter authorization beyond the vote to incur debt. Most wastewater infrastructure is too expensive to pay for in cash without borrowing; it must be financed over a long period of time during which revenues may be collected to pay for it. This section outlines several borrowing mechanisms available to municipalities:

- State Revolving Loan Fund,

- Rural Development loans from the US Department of Agriculture (USDA) and
- Conventional municipal financing.

Massachusetts also provides District Improvement Financing and the Local Infrastructure Development Program to help municipalities finance infrastructure development. All of these tools are described in more detail below. Each has its own cost, loan duration, use limitations and interest rate.

STATE REVOLVING LOAN FUND

The Massachusetts State Revolving Loan Fund (SRF) is a self-perpetuating loan fund administered by the State under the direction of the US EPA. The SRF program provides a low-cost funding mechanism to assist municipalities in complying with federal and state water quality requirements. The SRF program was originally funded by an act of Congress in 1987 as part of the implementation of the Clean Water Act and coincided with the decision stop providing federal capital grants to communities to build infrastructure. It is jointly administered by the Division of Municipal Services of the MassDEP and the Massachusetts Clean Water Trust (Trust). The state has two SRF programs, one for clean water and another for drinking water, which are administered by MassDEP. The clean water SRF may be used for planning or construction of wastewater and stormwater management systems. Eligible uses are outlined in the MassDEP regulations at http://www.mass.gov/eea/agencies/massdep/water/grants/state-revolving-fund.html. SRF loans vary by interest rate depending on the duration of the loan and locally-adopted regulations to manage growth after construction of the wastewater system.

Each year MassDEP solicits projects from Massachusetts municipalities and wastewater districts to be considered for subsidized loans. The current subsidy is provided via a 2% interest loan or, under certain growth-neutral criteria, 0% financing. Loans may be forgiven or partially forgiven. In recent years the program has operated with $300 to $350 million per year, representing the financing of 50 to 70 projects annually. The SRF Program continues to emphasize watershed management priorities. A major goal of the program is to provide incentives to communities to undertake projects with meaningful water quality and public health benefits and that address the needs of the communities and the watersheds.

Comprehensive Wastewater Management Plans (CWMPs) do currently have an advantage in receiving SRF funds.

ELIGIBLE PROJECTS

Financial assistance from the SRF is available for planning and construction of projects, including:

- combined sewer overflow (CSO) mitigation;
- new wastewater treatment facilities and upgrades of existing facilities;
- infiltration/inflow correction;
- wastewater collection systems;
- nonpoint source pollution abatement projects (e.g. landfill capping);
- community programs for upgrading septic systems (Title 5);
- brownfield remediation;
- pollution prevention;
- stormwater remediation;
- and climate change adaptation (e.g. stream bank stabilization and berms).

In addition, non-structural projects are eligible for SRF funding, such as planning projects for nonpoint source problems which are consistent with the MassDEP's Nonpoint Source Management Plan and that identify pollution sources and suggest potential remediation strategies.

For details on the application process see Appendix 6A.

On August 6, 2014, a bill aimed at "improving drinking water and wastewater infrastructure" was signed by the Governor as Chapter 259 of the Acts of 2014. The new law creates another form of financial assistance for communities with SRF loans - principal forgiveness. The Clean Water Trust, the entity that awards SRF loans, is now able to offer principal forgiveness so long as that subsidy does not exceed 25% of the total cost of all projects for the year, and does not exceed the equivalent of a 75% subsidy compared to a market rate loan.

The law also details how MassDEP may establish who is eligible for principal forgiveness. The project must satisfy one of the following criteria:

1. pursuant to an adopted regional wastewater management plan;
2. connects a local or regional government unit to a Massachusetts Water Resources Authority facility;
3. is a green infrastructure project, as defined in the bill;
4. uses regional water resources to offset local impacts of water withdrawals in the watershed basin of the receiving community;
5. is a direct result of a disaster subject to a declaration of emergency;
6. provides public water supply to consumers with contaminated groundwater or wells; or
7. uses innovative technology to improve drinking water infrastructure.

This plan recommends MassDEP exercise its discretion in providing principal forgiveness up to 25%.

Recommendation C6.1:
MassDEP should exercise its discretion in providing principal forgiveness up to 25%.

USDA RURAL DEVELOPMENT LOAN PROGRAMS

The United States Department of Agriculture (USDA) offers loans for water and wastewater disposal systems in rural areas and towns with populations below 10,000 and a median household income that meets certain guidelines. Funds may be used for "land acquisition, legal fees, engineering fees, capitalized interest, equipment, initial operation and maintenance costs, project contingencies, and any other cost that is determined by the Rural Development to be necessary for the completion of the project" (for more information visit: http://www.rurdev.usda.gov/UWP-dispdirectloansgrants.htm). The maximum loan term is 40 years and the interest rate is determined when the loan is negotiated.

CONVENTIONAL MUNICIPAL FINANCING

Conventional municipal financing occurs when a community uses its own full faith and credit to borrow money. A stand-alone bond sale relies on the bond rating of the community, which can create great variability in the interest rate paid. Many communities have limited bonding capacity and may have difficulty self-financing major capital wastewater infrastructure.

In addition to the local borrowing options described earlier in this chapter, Massachusetts offers two other programs that work with conventional financing – District Improvement Financing and Chapter 23L.

District Improvement Financing (DIF) allows the town to designate an area within which new property tax revenues generated from development may be used to pay off bonds issued to build public infrastructure, including sewer, which enables new development to occur.

Chapter 23L is a tax-exempt bonding program enabled through a public-private partnership to build public infrastructure improvements associated with a large development. In this case, the debt service is paid by a special property tax assessment, much like a betterment, that remains with the property if the property changes hands.

Paying for a Watershed Plan

While constructing wastewater treatment facilities is financed through loans and bonds, the incurred debt must be paid for with taxes, fees, unrestricted local aid from the state and grants. Such sources of funds are available at the local, state and federal level. The Section 208 Plan Update also recommends some additional methods for paying the cost of addressing the Cape's nutrient problem. The section below reviews a range of possible payment options that could be considered, but is not intended to be inclusive of all potential funding options.

LOCAL REVENUE

Local options to pay for the management of wastewater and stormwater fall into two categories: taxes and fees. Tax revenues may come from property taxes or local option

taxes, such as meals or room occupancy taxes. Betterments are a hybrid of taxes and fees and are assessed on properties that will be improved through the provision of public infrastructure. This method can be applied to traditional sewer or, potentially, other traditional and non-traditional water quality remediation methods that provide a direct benefit to an abutting property. Fees are payments for specific services such as the provision of water, electricity, or in this case, wastewater treatment. Fees are generally used to pay for the operation and maintenance of services being provided.

TAX OPTIONS

In Massachusetts and as described above, the main source of local revenue is property taxes. However, there are betterments as well as two local option taxes: meals tax and room occupancy tax. Other states have local option income taxes and local sales taxes, among others.

Property Tax

Taxes are broadly collected, based on property valuation and used to fund general services that benefit all taxpayers, whether they are direct users of a service or benefit indirectly through a stronger community and economy.

Property Tax Betterment

Property tax betterments are traditionally used to help pay for public water and sewer and road construction. Betterments are paid by property owners whose properties are bettered by public investment in infrastructure such as water or sewer service. The justification for such an assessment is that the market value of the property has increased for the owner as the result of a publicly-funded improvement. The betterment assessment transfers this market benefit back to the public from the property owner and is collected on tax bills. Betterments are used to pay for construction, but cannot be used to pay for the operation or regular maintenance of water or sewer systems.

Local Option Taxes

Massachusetts offers a local option tax on meals and a local option tax on room occupancy. Every town on Cape Cod has adopted the local option rooms tax and all but two towns have adopted the local meals tax (see **Table 6-1**). The Commonwealth does not restrict how these funds may be used. The town of Barnstable sought and received Special Legislation to have its 0.75% meals tax and 2% additional rooms tax (both made available in 2010) automatically flow to a dedicated Wastewater Infrastructure Fund to defray future costs.

	MEALS LOCAL OPTION		ROOMS LOCAL OPTION	
Municipality	**Local Tax Rate**	**Effective Date**	**Local Tax Rate**	**Effective Date**
Barnstable	0.75%	10/1/2010	6.00%	10/1/2010
Bourne	0.75%	7/1/2014	4.00%	7/1/1986
Brewster	0.75%	7/1/2010	6.00%	7/1/2010
Chatham	0.75%	7/1/2011	4.00%	7/1/1988
Dennis	0.75%	7/1/2010	4.00%	4/1/1987
Eastham			4.00%	1/1/1987
Falmouth	0.75%	1/1/2011	4.00%	1/1/1987
Harwich	0.75%	7/1/2010	4.00%	1/1/1987
Mashpee			4.00%	10/1/1986
Orleans	0.75%	7/1/2010	4.00%	4/1/1988
Provincetown	0.75%	7/1/2010	6.00%	7/1/2010
Sandwich	0.75%	7/1/2013	4.00%	7/1/1986
Truro	0.75%	7/1/2011	4.00%	12/1/1985
Wellfleet	0.75%	1/1/2010	4.00%	7/1/1986
Yarmouth	0.75%	7/1/2010	6.00%	7/1/2010

Local Option Meals Tax and Room Occupancy Tax Acceptance

Table 6-1

FEES

Fees are for direct services received such as the provision of water or other utility services and for licenses. In the context of wastewater, they may be used to fund the cost of operating, maintaining or constructing a wastewater management system.

STATE REVENUE

State revenue will likely come in the form of grants and lower interest rates on loans. Grants are outright support while lower interest rates save in the overall cost of servicing the debt incurred in building a system.

MASSWORKS GRANTS

The MassWorks Infrastructure Program provides grants for publicly owned infrastructure including but not limited to: sewers, utility extensions, streets, roads, curb-cuts, parking facilities, site preparation and improvements on publicly owned land, demolition, pedestrian walkways and water treatment systems to support three project types:

- Housing development at a density of at least four units to the acre (both market and affordable units);
- Transportation improvements to enhance safety in small, rural communities;
- Economic development and job creation and retention.

Applications are accepted once a year from municipalities and other eligible public entities.

FEDERAL CLEAN WATER ACT 604(B) WATER QUALITY PLANNING GRANTS

The Federal 604(b) Water Quality Planning Grants are administered by MassDEP. The grants may be used for watershed- or sub-watershed-based nonpoint source assessment and planning projects leading to the: 1) determination of the nature, extent and causes of water quality problems; 2) assessment of impacts and determination of pollutant loads reductions necessary to meet water quality standards; 3) development of green infrastructure projects that manage wet weather to maintain or restore natural hydrology; and 4) development of assessments, preliminary designs and implementation plans that will address water quality impairments in impaired watersheds.

During the course of the Section 208 Plan Update, several new funding sources became available to towns taking action to address nitrogen impacts in their watersheds.

STATE CAPITAL SPENDING PLAN

On August 13, 2014, the governor signed a $2.2 billion environmental bond bill into law, the largest in Massachusetts's history. The bond bill authorizes the State to fund projects that evaluate, protect and improve its environmental resources. Funding is now authorized for maintaining water quality, enhancing coastal infrastructure, managing waste, and supporting local fisheries and agriculture, among other programs. However, these types of projects must be included in the governor's annual Capital Spending Plan to be made available to Cape communities.

As part of an investment in Massachusetts' water quality, $4 million is authorized for monitoring programs, specifically to implement and evaluate adaptive management as it relates to the reduction of nitrogen pollution in coastal waters. The County is developing a strategy to partner with the Commonwealth to make this $4 million available to monitor water quality in locations where adaptive management is implemented.

An additional $4.5 million is authorized to be invested in pilot projects that aim to restore water quality of degraded estuaries in pursuit of TMDL compliance. The funding is designated for "innovative and green wastewater management technologies and approaches," including constructed wetlands, aquaculture, permeable reactive barriers, ecotoilets, and other technologies listed in the Technologies Matrix. The $4.5 million could also be spent on the installation of sustainable technologies at wastewater treatment facilities, such as co-digestion and resource recovery, that will target regional needs.

Both investments require monitoring programs and pilot projects to be "consistent with a current area-wide water resource management plan adopted under Section 208 of the Federal Clean Water Act."

The Commonwealth of Massachusetts should make funds designated for monitoring programs and pilot projects available to Cape Cod for efforts that are consistent with the Section 208 Plan Update.

Recommendation C6.2: The Commonwealth of Massachusetts should make funds designated for monitoring programs and pilot projects available to Cape Cod for efforts that are consistent with the Section 208 Plan Update.

FEDERAL FUNDING

Similar to state funding, federal support will likely be found through grant programs or loan forgiveness programs for construction.

USDA GRANTS

The purpose of USDA grants is to develop water and waste disposal systems in rural areas and towns with populations not in excess of 10,000. The funds are available to public bodies, non-profit corporations and Indian tribes. To qualify, applicants must be unable to obtain the financing from other sources at rates and terms they can afford and/or their own resources. There are some systems that qualify for grant funding; however, grant funding availability is limited. Program details are available on the USDA website: http://www.rurdev.usda.gov/UWP-dispdirectloansgrants.htm.

US ECONOMIC DEVELOPMENT ADMINISTRATION (EDA) GRANTS

EDA grants are meant to support the development and implementation of economic development strategies for economically distressed communities. Funding priorities are given to investment applications that support long-term, coordinated and collaborative regional economic development approaches; innovation and competitiveness; entrepreneurship; and strategies and investments that connect regional economies with the worldwide marketplace. Additional consideration will be given to investment applications that respond to sudden and severe economic dislocations, including natural disasters; enable the transition of Base Realignment and Closure (BRAC) impacted communities; support EO 13287, Preserve America; and promote the revitalization of brownfields. EDA grants may be used to pay for the design phase of capital construction projects. Awards are between $500,000 and $5 million, the larger size being very rare. Applications are accepted on a rolling basis.

HUD COMMUNITY DEVELOPMENT BLOCK GRANTS

Community Development Block Grants (CDBG) may be used to finance wastewater infrastructure. The CDBG Program is administered by the United States Department of Housing and Urban Development (HUD) in partnership with municipalities above a certain size and for other communities through the states. No less than 70% of CDBG funds must be used for projects that directly benefit low- and moderate-income persons. To be eligible, projects must also meet one of three national objectives: benefit low- and moderate-income persons, prevent or eliminate slums or blight, or address community development needs having a particular urgency because existing conditions pose a serious and immediate threat to the health or welfare of the community for which other funding is not available. CDBG funds may be used to build or expand wastewater infrastructure. They may not be used to defray repair, maintenance, or operating costs. The towns of Barnstable and Yarmouth are entitlement communities, meaning they get CDBG funds directly from HUD. The remaining towns may apply to the state to compete for CDBG funds. The CDBG Program, in addition to providing grants, also includes a loan program, "Section 108," which enables CDBG entitlement communities to borrow up to five times their annual entitlement grant. The entitlement community pledges current and future CDBG funds as security for the loan. Non-entitlement communities may also use this program but must do so through an agreement with the state. The maximum loan duration is 20 years.

US EPA NONPOINT SOURCE SECTION 319 GRANT PROGRAM

Under section 319 of the Federal Clean Water Act, US EPA annually provides grants to states for controlling nonpoint sources of pollution, such as agricultural runoff, mining activities and malfunctioning onsite septic systems. In Massachusetts these grants are administered by MassDEP. In states where onsite systems have been identified as a significant source of such pollution, the section 319 funds may be used to construct, upgrade or repair onsite systems.

US EPA STAR GRANTS

The Science to Achieve Results (STAR) grant program funds targeted research on environmental science and

engineering issues through a competitive process. The National Center for Environmental Research names areas of natural concern. At present, these centers focus on children's health, hazardous substances, particulate matter and estuarine and coastal monitoring. Those eligible for STAR grants include academic and non-profit institutions in the United States, as well as state, local and tribal governments.

POTENTIAL NEW REVENUE SOURCES

Much of this plan focuses on ways to lower the overall cost of reducing the impacts of nitrogen from wastewater, stormwater and fertilizer on coastal water quality. Still, the remaining costs are burdensome to the year-round population of Cape Cod. Having done its share to lower costs, the Cape now looks to alternatives to property taxes and fees to help finance the cost of preserving the economic benefits that a healthy Cape Cod provides to the rest of the Commonwealth. The Commission encourages implementation of additional funding sources to more fairly

LOCAL/REGIONAL: NITROGEN IMPACT FEES

New development located where it must rely on septic systems should participate in managing the nutrient loading problem on Cape Cod. This can be achieved by applying a nitrogen impact fee to new development dependent on traditional septic systems. The fee could be based on the amount of nitrogen generated by the development, and would internalize the cost of nutrient mitigation of the additional loads attributable to the property. The fee will encourage new development to locate in areas already served by wastewater treatment systems that remove nitrogen, an objective of the Regional Policy Plan. See the discussion on impact fees in Chapter 7 for more information.

Recommendation S6.3: The Cape Cod Commission shall evaluate the steps required for a regional or locally based nitrogen impact fee.

REGIONAL: SEPTIC TRUST FUND

A Septic Trust Fund should be established to optimally manage the maintenance, repair, and replacement of septic systems. In exchange for an annual fee, property owners served by traditional septic systems would have their systems regularly pumped out, repaired as needed, and replaced with a standard Title 5 system when necessary. The benefits of the program would be to extend the life of existing septic systems, lower overall replacement costs, optimize the treatment of septage by managing the timing of treatment at septage treatment facilities and relieve the homeowner from the high cost of replacement upon failure of their septic system.

Recommendation C6.4: The Cape Cod Commission shall develop a proposal for a Septic Trust Fund and pursue authorizing legislation.

REGIONAL: CAPE COD CAPITAL TRUST FUND

The Cape Cod Commission should identify and allocate resources to develop a revolving loan fund to finance infrastructure development on Cape Cod, particularly as it relates to water quality. A Cape Cod Capital Trust Fund for infrastructure financing should be established. The Trust Fund would be a regional entity with a professional staff experienced in public finance and would focus on providing funding for design and other aspects of infrastructure development not supported by other funding agencies at the state and federal levels. The Trust Fund would provide towns with additional funding at low interest rates to complete the design and construction of infrastructure needed to establish a sustainable economy on Cape Cod that does not negatively impact the environment and rectifies past negative impacts on the region's natural resources.

Recommendation C6.5: The Cape Cod Commission shall develop a proposal for a Cape Cod Capital Trust Fund for the financing of infrastructure design and construction.

STATE: WATER MIL CHARGE

One potential source of funding for wastewater infrastructure projects is an excise tax on water consumption, as recommended by the Massachusetts Legislature's Special Blue Ribbon Commission on Water

and Wastewater Infrastructure. An excise tax millage of one to three mils per gallon could be paid into a specific fund that could be used for necessary capital repairs and the replacement of aging infrastructure related to drinking water and wastewater (e.g. Title 5 Systems).

In the Boston Globe on April 13th, 2011, it was stated:

"Massachusetts has more than 20,000 miles of sewer and 21,000 miles of water pipes, and most of those pipes were installed more than 50 years ago… A draft… recommendation presented at yesterday's meeting [of the Special Blue Ribbon Commission] describes as a "good first step" a statewide surcharge of 1 mil per gallon — a mil equals one-tenth of one cent — on residential and commercial wastewater and drinking water.

Under the 1-mil scenario, the added cost per individual would be $23 per year, based on the state's goal for individual water consumption of 65 gallons per day."

If adopted by the state Legislature, a one mil charge would result in annual revenue of $81,993,600, based upon annual household water usage of 65 gallons per person per day and the total population on Cape Cod. Over 20 years, the excise would generate $1.64 billion, and $4.10 billion would be generated over 50 years.

This funding source is attractive as it is directly related to wastewater, and it discourages the excessive household use of water and should be pursued.

OTHER CONSIDERATIONS:

ALLOCATING COSTS IN SHARED WATERSHEDS

In shared watersheds, towns working together must agree upon a methodology to allocate costs. One approach may be to allocate costs proportionally to the share of nitrogen contributed to the watershed by each town. See Chapter 8 for a discussion on allocating responsibility, the requirement of Section 208 of the Federal Clean Water Act to designate Waste Management Agencies to take responsibility for nitrogen, and ways in which to collaborate.

ENVIRONMENTAL JUSTICE

Title VI of the Civil Rights Act of 1964 prohibits discrimination by recipients of federal financial assistance on the basis of race, color and national origin, including matters related to language access for limited English proficient (LEP) persons.

As federal financial assistance will be sought in support of this Section 208 Plan Update, it is incumbent upon the local and regional governments that may receive such assistance to have appropriate Title VI programs, including an effective Public Participation Plan. Outreach to all populations on planning decisions related to cost, affordability and the siting of potential technologies and infrastructure resulting from this plan, among other considerations, not only ensures compliance but can stimulate wider community discussion and acceptance of selected options.

The year 2014 marked the 20th anniversary of the signing of Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations. Because of this legislation federal agencies are required to, "identify and address the disproportionately high and adverse human health or environmental effects of their actions on minority and low-income populations, to the greatest extent practicable and permitted by law." The order also directs each agency to develop a strategy for implementing environmental justice (EJ).

Key principles of environmental justice include:

- Avoiding, minimizing or mitigating disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority and low income populations; and
- Ensuring the full and fair participation by all potentially affected communities in the decision making process.

There are a number of designated environmental justice communities on Cape Cod. An area is described as an EJ area when the median household income of the census block group is equal to or less than 60% of the Barnstable County median household income, while also accounting for areas where 15% or more residents of Census block group identify as a race other than white.

In 2011, US EPA published Plan EJ 2014, the Agency's overarching strategy for advancing environmental justice. The Plan has three goals:

- Protect health and the environment in overburdened communities;
- Empower communities to take action to improve their health and environment; and
- Establish partnerships with local, state, tribal, and federal governments and organizations to achieve healthy and sustainable communities.

In overburdened communities, barriers can include lack of trust, lack of awareness or information, lack of ability to participate in traditional public outreach opportunities, language barriers and limited access to technical and legal resources. More transparency and dialogue can to lead to more meaningful engagement and participation of overburdened communities in the permitting process. More meaningful engagement, in turn, can lead to better permit outcomes for communities as well as permit applicants.

The planning and implementation of the Section 208 Plan Update will continue to facilitate outreach and participation in all aspects of the plan and permitting, and particularly as it relates to paying for the infrastructure necessary to meet water quality goals. While not every action may be legally required of regional and local governments as they pursue plan implementation, a robust outreach process is recommended as it leads to a more successful conclusion, as more participation leads to community acceptance of solutions chosen and implemented.

Recommendation S6.6:
Implementation of the Section 208 Plan Update shall include a local public participation process that includes efforts specifically designed to reach environmental justice communities.

Section 208 Plan Update Finance Model - A Tool for Towns to Utilize

As part of the Section 208 Plan Update, the Cape Cod Commission is providing communities with a model that will help them plan and manage the costs of building infrastructure to meet TMDLs for nitrogen in impacted watersheds. The Finance Model will be available to communities through the Commission's Watershed Team technical assistance program, described in Chapter 5.

PURPOSE

The model, developed by the Cape Cod Commission, AECOM Technical Services, Inc., and the Abrahams Group, estimates the total cost to build, finance and operate a proposed set of solutions and helps determine if the plan is affordable to the average household. The model is also designed to indicate if municipalities included in a proposed nutrient reduction scenario have the capacity to cover the total costs given current tax and borrowing restrictions. The model then allows users to select from a variety of potential revenue sources to determine how to best pay for the scenario proposed. This tool can assist in general policy discussions but is not a substitution for detailed financial planning.

MODEL STRUCTURE

The model includes three modules:

- Cost Module
- Financing Module
- Revenue Module

The Cost Module determines direct capital, operation and maintenance, and monitoring costs by individual technology. Financing costs are determined in the Financing Module, which allows users to select between various financing options appropriate for each technology solution included in the proposed scenario. The module then calculates the annual cost of a proposed scenario, including loan fees and interest payments. The final step is the Revenue Module, which allows users to select different methods to pay for the solution, including the financing costs. These modules are discussed in detail in the rest of this section.

COST MODULE

The Cost Module is based on cost estimates included in the Section 208 Plan Update Technologies Matrix (described in

Chapter 4), which is also the basis for the scenario building and decision support tools developed during the Section 208 Plan Update process.

This model will show capital costs by technology solution for any given scenario, which can be expected to include a variety of technologies selected by the user. Defining costs by individual technology is essential given the eligibility requirements of different financing programs and revenue sources. Land costs are not included in the total capital cost; however, the availability of municipally-owned land was a determinant in identifying potential sites for implementing technologies.

The model also includes the total operation and maintenance costs for the full scenario over time, as well as annual monitoring costs for each technology.

FINANCING MODULE

The Financing Module focuses on how money needed to build capital infrastructure will be obtained up front and paid for over time, which requires borrowing from state, federal and regional sources as detailed above. The model will allow users to select different borrowing options for different technologies included in proposed scenarios to allow for variability in financing eligibility and borrowing costs.

The model includes amortization tables for each type of SRF loan in order to calculate annual costs of the loan repayment process, including:

- SRF programs for clean water and drinking water; and
- USDA Rural Loan program.

The Financing Module also provides the ability to calculate debt service schedules and maturing principal and interest payments for conventional financing with general obligation bonds, including short-term bonds in anticipation of borrowing (BANs), long-term general obligation bonds and debt issuance costs.

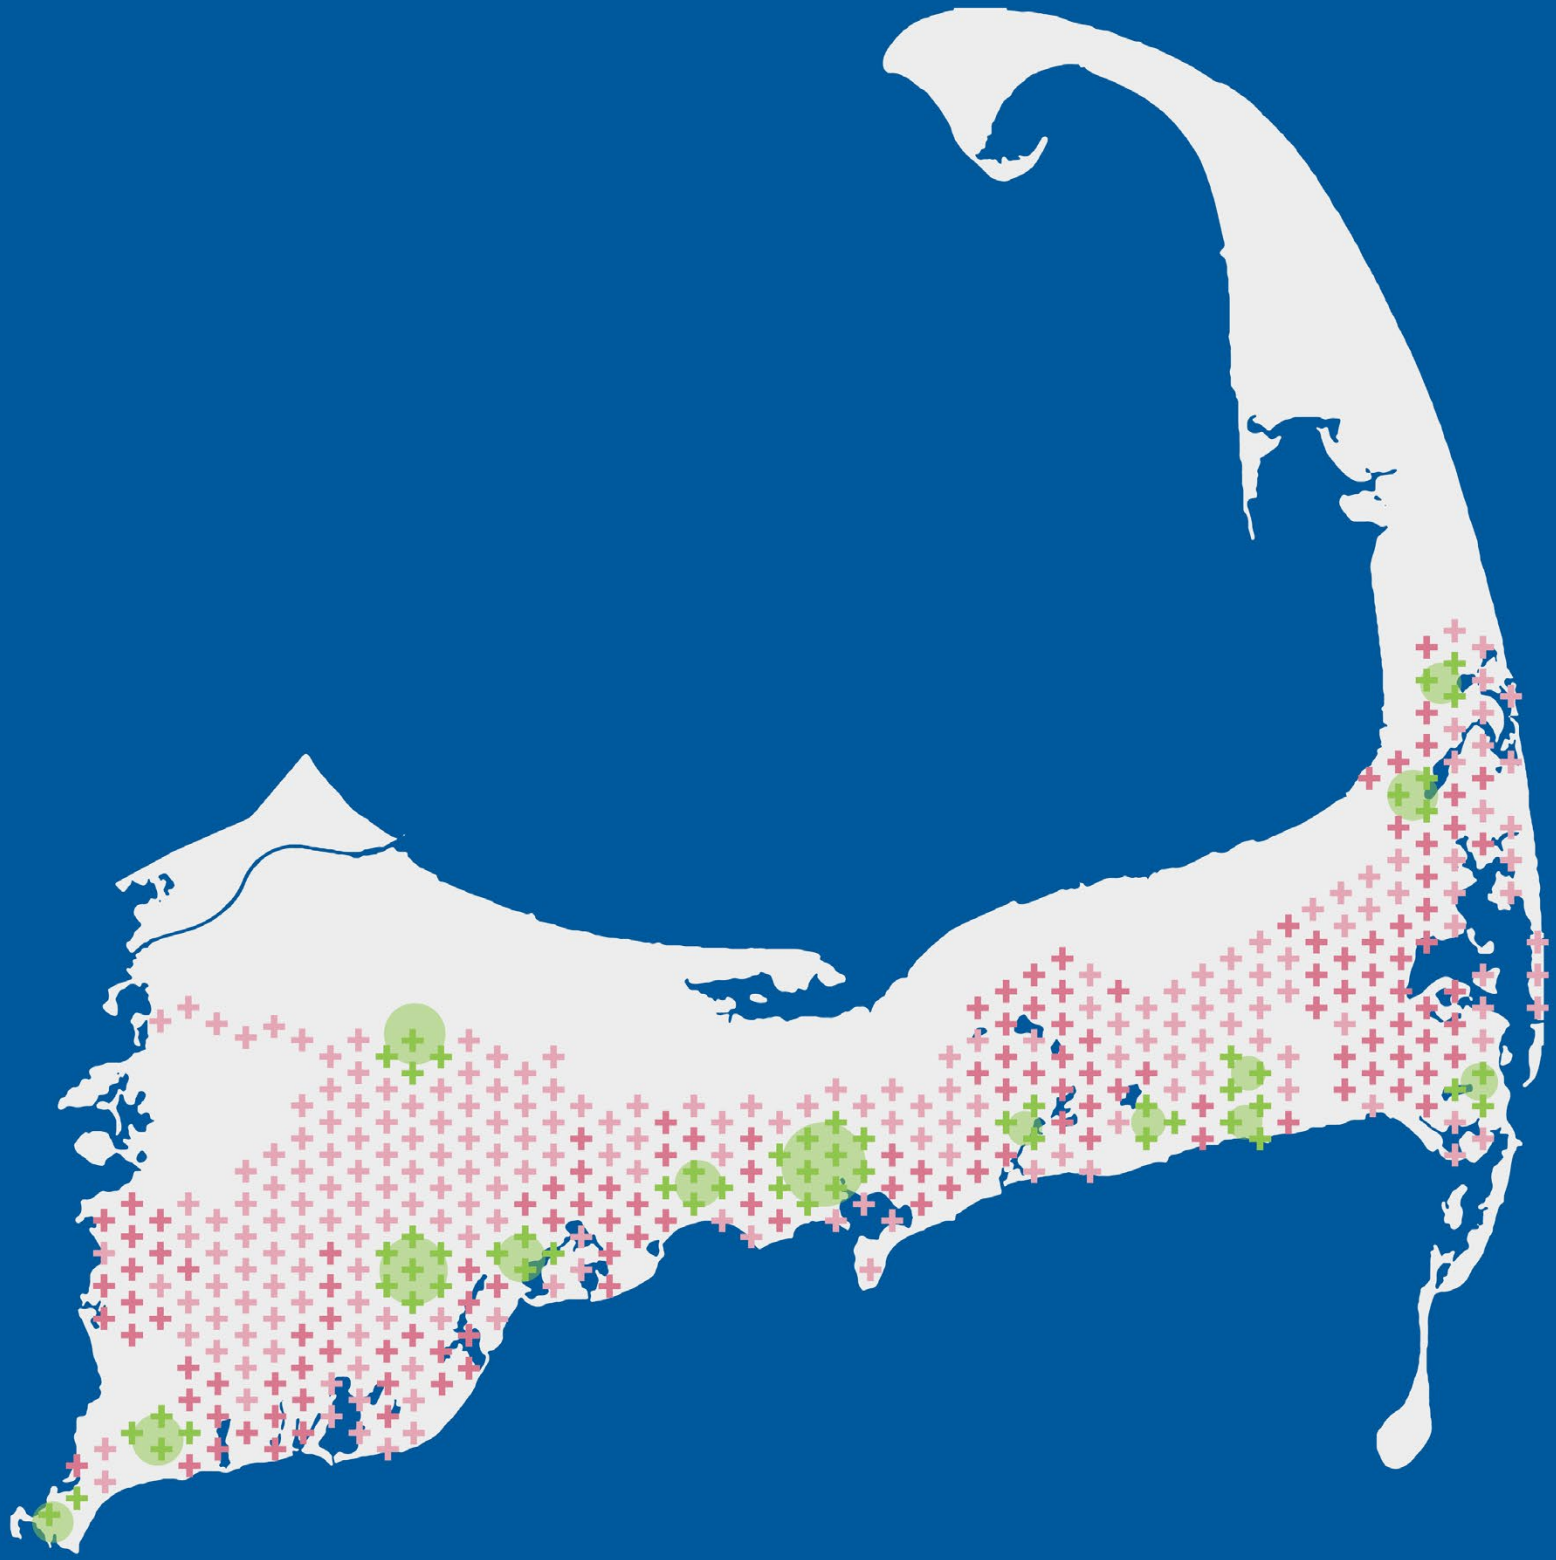
REVENUE MODULE

The Revenue Module will help policymakers assess the different options available for payment of the costs associated with the proposed set of technology solutions. The module allows the user to pick from the variety of funding sources described previously in this section. These range from general property taxes, to property tax betterments, to state or federal grants. The module is flexible to allow for the addition of new revenue sources as they become available.

07 BALANCE

Planning & Growth Management

Open space is one of the region's most valuable assets. Naturally forested open space also provides a valuable nitrogen "sink" as natural systems attenuate nitrogen contributions from atmospheric deposition. The rapid development pressure of the 1980s led to decreased open space and focused attention on the need to manage growth, guide land use, promote balanced economic growth, provide for adequate capital facilities and infrastructure, and protect environmental resources. Towns need to stimulate their tax base in order to afford the wastewater costs necessary to meet water quality standards and, at the same time, the economic development necessary to achieve that result is limited by the problem that needs to be solved. Without additional ability to treat wastewater, towns don't have the capacity for appropriate patterns of growth that don't add to the cost of remediating marine ecosystems.

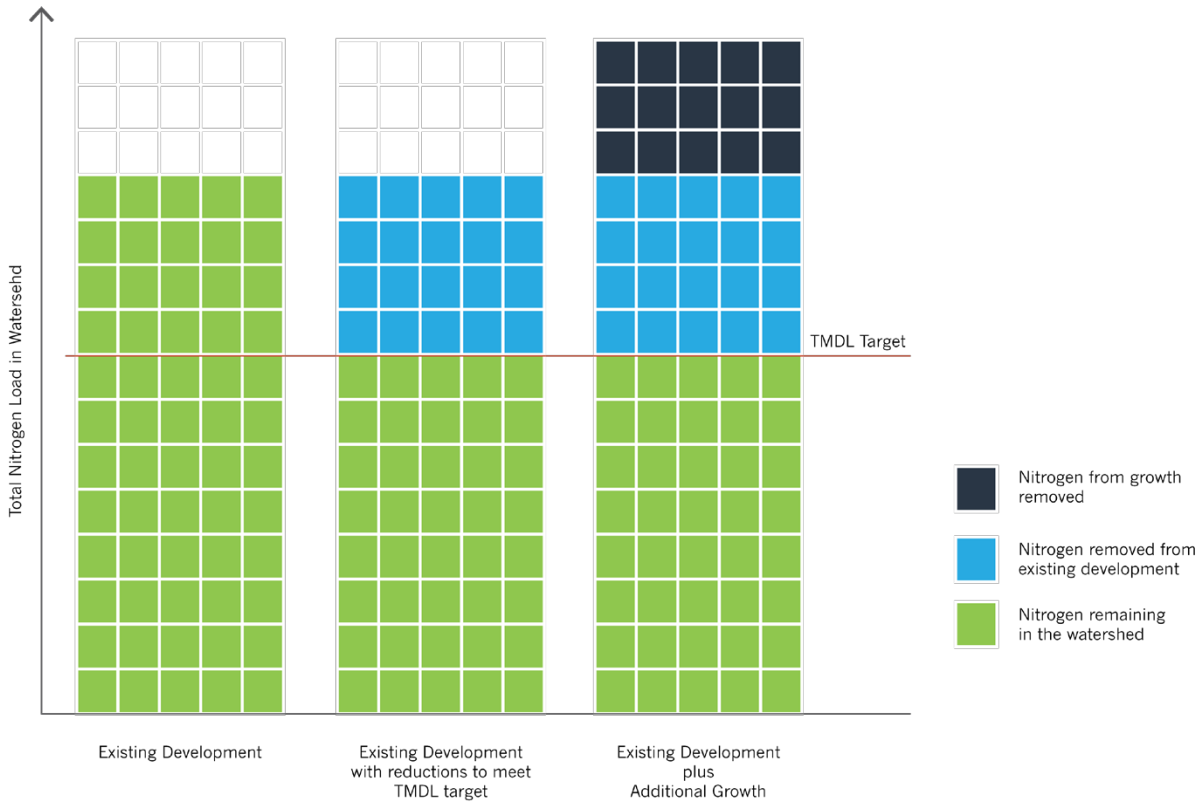


Managing Growth

Once nitrogen loads are sufficiently mitigated for existing development, 100% of the load from new development must also be mitigated in order to continue to achieve water quality goals (**Figure 7-1**).

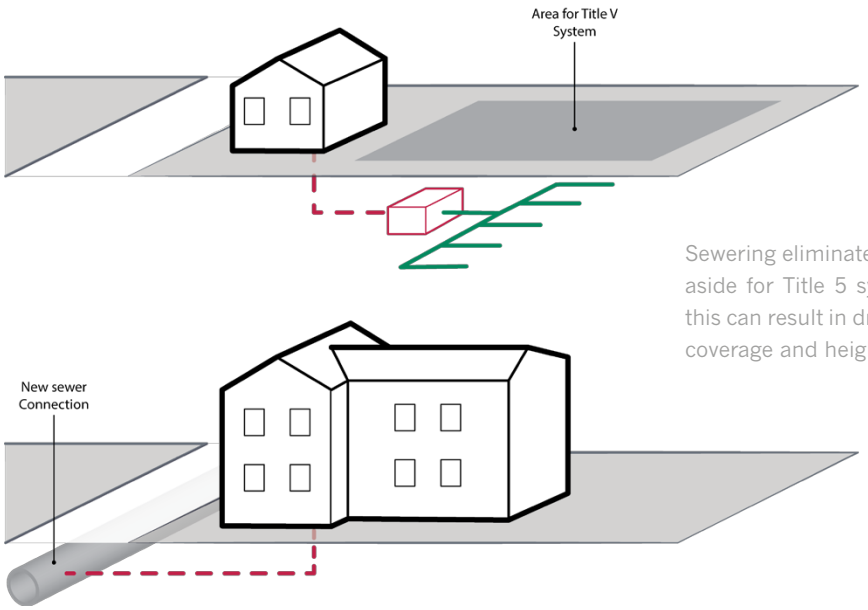
Projected growth can be significant in some towns and watersheds. The Cape-Wide Buildout Analysis to Support Regional Wastewater Planning was conducted by the Commission in 2012 with a grant from the Massachusetts Department of Environmental Protection (MassDEP).

Image on facing page: Cape Cod's water resources drive the regional economy. Development, or redevelopment, in watersheds to nitrogen impaired water bodies has the potential to further degrade water quality. Towns must continue to grow to promote a vibrant community. New growth has the potential to provide for a net nitrogen reduction if it occurs in places suitable for cost effective connection of existing properties to wastewater infrastructure.



100 Percent Future Nitrogen Removal

Figure 7-1



Sewer Induced Growth

Figure 7-2

The analysis identified the following potential municipal growth projections.

- Municipal residential growth for individual towns is estimated between 8% and 58% of new residential units. A Cape-wide average of 18% growth in additional residential units is projected.
- Municipal non-residential growth for individual towns is estimated between 8% and 163% of new square footage. A Cape-wide average of 53% of new square footage is projected.

The cost of addressing 100% of nitrogen from new growth can be substantial. "Estimating Cape-Wide Costs of Wastewater Infrastructure," a report dated March, 2013, identified additional costs of growth, assuming a 15% and 30% increase over current wastewater flows and assuming the construction of traditional wastewater infrastructure. That analysis showed that a 15% growth in wastewater flow translates to a 20% increase in capital cost. A 30% growth increases the capital cost by 40%. Because wastewater collection costs represent about 70% of the cost of constructing a system of sewers, treatment plants, and effluent disposal facilities, costs to mitigate nitrogen from new growth can be reduced by promoting density and discouraging sprawl (Cape Cod Commission 2013).

SEWER INDUCED GROWTH AND SMART GROWTH

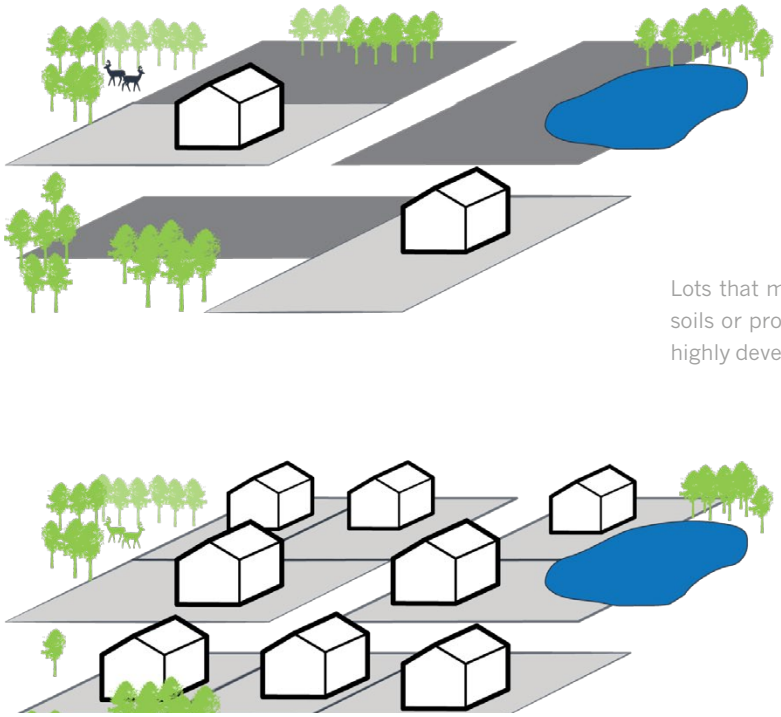
The Commonwealth of Massachusetts' Title 5 regulations for on-site systems can limit the amount of development on parcels where sewer or other wastewater treatment technology is not available. In some cases, property owners may not be able to add additional bedrooms or dwelling units allowed under zoning because the parcel relies on a septic system for wastewater management. Removing a parcel's septic system and connecting it to wastewater treatment lifts such as Title 5 restrictions and can result in additional development (**Figure 7-2**).

Both the Commonwealth and the Commission support well-planned growth to enhance community character, preserve high-quality open space, improve and support municipal budgets and improve impaired areas. To help reshape the development pattern on Cape Cod, measures must be taken to encourage mixed-use and compact forms of development (encouraging density) in existing centers and discourage sprawling development in sensitive areas. There are several ways in which this can be accomplished. First, the 2009 Regional Policy Plan (RPP) encourages mixed-use development in Economic Centers and infill in Villages as appropriate. To accomplish this, a Regional Land Use Vision Map (RLUVM) was created as the basis for such planning, helping to identify areas appropriate for

additional development and focusing on specific types of development, as well as those areas where such activity should be discouraged. As the Commission undertakes the five-year revision to the RPP in 2015, there is an opportunity to revisit the RLUVM to align desired future growth patterns with wastewater infrastructure planning. In addition, Cape Cod towns could change local zoning bylaws to support mixed-use and compact development. Finally, the state offers incentives to local governments that put policies in place to encourage such growth patterns. Areas that are eligible for the state incentives include:

- Areas near transit stations, including rapid transit, commuter rail, and bus and ferry terminals;
- Areas of concentrated development, including town centers, other existing commercial districts, and existing rural village districts; or,
- Areas that by virtue of their infrastructure, transportation access, existing underutilized facilities, and/or location make highly suitable places for residential or mixed-use smart growth zoning districts.

In the absence of Title 5 regulated septic systems, there is potential for uncoordinated and unplanned growth (**Figure 7-3**). A variety of regulatory and land use planning tools can be put in place at regional and local levels to manage growth in the absence of Title 5 and growth induced by sewers outside of defined growth areas. As towns move forward with local implementation of watershed-based plans and/or municipal wastewater management plans,



Increased Density as a Result of Proximity to Sewer

Figure 7-3

a combination of approaches will be needed to manage growth, meet community goals and protect natural resources and community character.

A review of Comprehensive Wastewater Management Plans (CWMPs) across the region shows that many of the areas targeted for collection systems do not always conform to growth center boundaries, and often extend well beyond what communities consider the boundary of a village or economic center. This overlap of nitrogen management areas with existing and desired growth patterns in Cape communities requires consideration of a combination of growth management tools to achieve water quality goals, while maintaining community character and preventing further sprawl and over-development. Such tools include: open space protection, transfer of development rights (TDR) sending and receiving districts, tax increment financing, checkerboarding, and zoning and regulatory changes. These and other planning and growth management tools are discussed further below.

The Section 208 Plan Update recommends that a range of technologies be considered at the watershed level. Those

that utilize a collection system and those that enhance natural systems or are located on-site all may play a role in remediation efforts. Communities may choose to construct sewer systems for a variety of reasons. The major objectives of collecting wastewater flows for treatment is to restore or protect the health of coastal embayments. In designing systems to achieve this important goal, communities need strategies to ensure that the location of collection systems does not facilitate growth patterns that threaten community character or encroach on habitat and natural resources. Additional considerations that should be addressed in designing systems include environmental issues such as failing Title 5 systems, drinking water issues, freshwater pond degradation due to phosphorus and the provision of infrastructure to support economic growth. There are several broad principles that communities should consider when coordinating community character goals with planning for sewer infrastructure:

- Coordinate watershed infrastructure planning to ensure that total maximum daily loads (TMDLs) are met and are met for current and future conditions. Sewer system capacity designed to meet TMDLs will take into account build-out within the entire watershed, even if the entire watershed is not sewered. This is because unanticipated growth outside the sewered area of a watershed with a TMDL could also result in increased nitrogen loading to the watershed. This additional growth could cause the watershed to exceed the level of total nitrogen from effluent consistent with TMDLs and require sewering of additional areas.
- Allocate limited collection system capacity to areas and uses that support broader community planning goals.
- Provide treatment capacity needed to achieve TMDLs through collection system design. In many towns there may be multiple system design alternatives that could meet that objective. One of the criteria used to select among alternatives should be how the collection system configuration would facilitate desired land use patterns in terms of the type, location or intensity of growth. Similarly, the selected alternative should not facilitate intensification of undesired growth. See also the discussion of "checkerboarding" sewer collection systems below.
- Ensure that community character and natural resources are protected or enhanced.

The 2009 RPP is currently being updated. Part of the RPP update includes the development of a decision support tool (Envision Tomorrow) that allows communities to test alternate land use scenarios, and instantly see the effects of their land use choices across a variety of criteria such as jobs, housing, transportation systems and the municipal tax base. Envision Tomorrow and other tools made available through the section 208 process will provide communities with valuable information to aid decisions about whether, and where, collection systems for sewers may be most appropriate.

OPEN SPACE PROTECTION

Open space is one of the region's most valuable assets. Naturally forested open space also provides a valuable nitrogen "sink" as natural systems attenuate nitrogen contributions from atmospheric deposition. Nearly 30% of the Cape's upland is currently protected as open space. This significant accomplishment can be attributed to foresight and investment by all levels of government: designation of the Cape Cod National Seashore in 1961 by the federal government; establishment of the 1,900-acre Nickerson State Park in Brewster and 700-acre Shawme Crowell State Forest in Sandwich; the approximately 15,000 acres within Joint Base Cape Cod protected as public conservation land since 2002; and protection of large town-owned conservation areas such as the 4,700-acre Sandy Neck Park in Barnstable, the 383-acre Beebe Woods in Falmouth, and the 800-acre Punkhorn Parklands in Brewster. In recent years, Cape communities significantly increased local land in conservation through smaller purchases, ranging in size from one or two acres to over 200 acres. Due in large part to the adoption of the Cape Cod Land Bank in 1999 and the Community Preservation Act in 2005 as local revenue sources for open space acquisition, Cape towns protected more than 4,000 acres of open space through strategic acquisitions of lands of conservation interest. Many Cape communities sought to protect significant natural and fragile areas and outstanding water resources, including lakes, rivers, aquifers, shore lands and wetlands.

Private land trusts play a vital role in land protection as well. Land trusts can serve as valuable intermediaries in preserving lands through less expensive means than

outright acquisition, such as accepting charitable donations or purchasing conservation restrictions. Private trusts are also valuable partners with towns in conserving key properties. Trusts are able to reach out to their membership and raise funds for acquisitions, a role that towns cannot perform.

Grants are also an important source of funds for acquiring land. The Cape has been fortunate in attracting significant outside funding in recent years through state, federal and private grants. This may be attributed to off-Cape recognition of the sensitivity of the natural resources on the Cape, and support for protecting cohesive habitats, recreation areas and water supply protection areas.

While growth management has not typically been the driving force behind open space acquisitions, it has become a significant side effect of conserving land. Future growth potential on the Cape has been managed or reduced through the dedicated efforts of governments and private organizations to permanently protect open space on Cape Cod. This Section 208 Plan Update recommends continued acquisition of protected open space to protect sensitive environmental areas, decrease potential for sprawl development, and maintain natural, forested areas that attenuate nitrogen contributions from atmospheric deposition.

CHECKERBOARD SEWER INFRASTRUCTURE

Prior to the passage of Section 10 of the Environmental Bond Bill in 2008, in the absence of special legislation, towns were required to connect all properties that had frontage along a sewer line. This law deprived towns the ability to identify areas that were and were not appropriate for future growth and redevelopment. In some cases, large vacant tracts of land with frontage, or parcels with redevelopment potential at significant densities, forced communities to design for more treatment and disposal capacity than they wanted, and subjected portions of the community to inappropriate growth. Since the passage of the Environmental Bond legislation in 2008, towns may adopt the provisions of the recently amended Massachusetts General Law (MGL) Chapter 83 to accomplish "checkerboarding." This authority allows communities to coordinate land use planning with planning for wastewater infrastructure in a way that supports smart growth development patterns. In order for a town to utilize the checkerboarding provision, it must have a MassDEP-approved wastewater management plan that clearly differentiates properties requiring sewering and those that do not.

FLOW NEUTRAL PLANNING

The passage of Section 5 of the 2008 Environmental Bond Bill provides towns access to State Revolving Fund (SRF) loans without interest for construction of wastewater infrastructure projects intended for nutrient management that meet certain criteria (Chapter 312 of the Acts of 2008).

The availability of zero rate of interest SRF loans is contingent upon a town's ability to demonstrate that sewers will not enable more growth than otherwise would be allowed under zoning and current wastewater regulations. For example, among the criteria required to access the zero percent SRF funds, a town must have adopted land use controls intended to limit wastewater flows to a level that would have been allowed under regulations in effect when the wastewater management plan was approved. These flows are calculated in the aggregate with flexibility to allocate flows for new growth and expansions of existing development. Flows associated with undeveloped and underdeveloped parcels can be allocated to areas identified for mixed use and compact development. Mandates for water saving devices can also accommodate new growth.

Consistent with the goals of the Environmental Bond Bill, towns should correlate land use planning with wastewater infrastructure planning examine zoning and land use regulations to ensure that sewers meet the resource protection and growth management goals of the community, and support growth where it is desired. Towns should also consider adopting sewer system checkerboard authority to implement growth management goals.

MassDEP has promulgated regulations (310 CMR 44.00) prescribing how towns should conduct a buildout analysis to demonstrate baseline flows, and requiring towns to provide proof of adoption of flow neutral land use controls. To date, Cape Cod towns seeking zero interest loans have adopted sewer and board of health regulations and bylaws limiting flows from new development and redevelopment. One example of such regulation is from Chatham, which adopted a sewer department regulation. The Chatham regulation limits existing structures to flows that existed prior to the development of sewer infrastructure. Flows from undeveloped parcels are limited to flows allowed by

Title 5 or Chatham Board of Health regulations. Variances for additional flows may be granted if allocated from the Chatham Sewer Bank by the Chatham Board of Water and Sewer Commissioners. Other Cape communities have adopted regulations allowing existing residential structures to add a bedroom or to add up to a maximum amount of flow upon connection to sewer.

LONG-TERM PLANNING

LOCAL COMPREHENSIVE PLANS

The Cape Cod Commission Act promotes the establishment of local planning committees in Cape towns to prepare, update and implement Local Comprehensive Plans (LCPs). Through the LCP and in consultation with the Commission, each town defines its vision for how to achieve the goals of the Act and articulates the town's growth policy. In addition, the LCP is an information source about existing and expected conditions. Implementation of an LCP through changes in local zoning or other actions can help a town manage growth and its impacts on local and regional resources, and to plan for and fund adequate infrastructure and capital facilities. Eleven of the 15 Cape towns have adopted LCPs that have been certified by the Commission as consistent with the RPP. Several towns are currently undertaking LCP updates or, in the case of Brewster, its first LCP effort. The LCP process provides an excellent opportunity for towns to create the vision and goals for managing growth on the local level.

LAND USE VISION MAPPING

The Commission has worked collaboratively with Cape Cod towns to develop a vision for the future of Cape Cod through adoption of local Land Use Vision Maps (LUVMs) that categorize Economic Centers, Villages, Industrial and Service Trade Areas, and Resource Protection Areas. The maps provide a framework for regional land use planning and identify discrete areas to focus future development activities as well as areas for additional protection. Towns with an endorsed LUVM may apply for flexible thresholds that trigger the Commission's regulatory review of Developments of Regional Impact (DRIs). The Land Use Vision Map is also a tool to encourage towns to consider zoning and other changes to guide growth toward desired areas that have infrastructure to support it and away from areas that have significant ecological or cultural resources that could be degraded by inappropriate development. To date, eight of the 15 towns on Cape Cod have adopted a LUVM with the town of Bourne partially designated. The 2015 update to the 2009 RPP will likely result in a further refinement of these growth and protection areas across the region.

GROWTH INCENTIVE ZONES

The Commission adopted Growth Incentive Zone (GIZ) regulations in 2005, establishing a process for directing development and redevelopment into areas with adequate infrastructure and away from sensitive resources areas. GIZs facilitate mixed-use compact development and redevelopment. By creating a master plan and providing infrastructure and mitigation strategies to accommodate development, a town can pursue reduced regulatory involvement by the Commission for projects proposed within the zone. To establish a GIZ, a town must first ensure that all growth is properly served by infrastructure. Towns may request modifications to existing DRI thresholds as part of the GIZ designation. To date, three GIZs have been designated by the Commission, including:

- Main Street Buzzards Bay - Bourne (2012)
- Route 28 Corridor - Yarmouth (2007)
- Downtown Hyannis - Barnstable (2006)

Downtown Hyannis is served by the Hyannis Water Pollution Control facility. Main Street Buzzards Bay is partially sewered and the town of Bourne has contracted to treat and dispose of a limited amount of wastewater in Wareham. Bourne is currently in the process of examining options for collection, treatment and disposal to bring additional wastewater capacity to Buzzards Bay to support new development and redevelopment.

ZONING

Zoning represents the primary tool for regulating land use. MGL Chapter 40A, the state's zoning act, enables cities and towns to establish zoning regulations designed to achieve broad purposes including protection of public safety and welfare, lessening congestion and encouraging the most appropriate use of land in a community. Municipal planning boards are responsible for land use planning and administration and are authorized by the zoning act to prepare zoning amendments for town meeting vote.

Through zoning bylaws, communities set forth development standards such as minimum lot size, maximum density, site coverage, setbacks, building height and other dimensional requirements. Zoning also controls what types of uses are permitted and where in order to minimize conflicts between uses and allow for the types of development desired by a community. Zoning is a powerful tool and has a significant impact on development patterns and character of a community. The adage "you get what you zone for" aptly characterizes the power of zoning regulations.

Municipal planning boards may draft revisions to the zoning bylaws to address development and land use issues. Adoption of proposed changes requires a two-thirds majority vote by a town's legislative body. While zoning changes are applicable to new development, the state zoning act provides extensive protections to legally established pre-existing uses or structures, including undeveloped subdivisions, allowing them to continue without meeting new zoning requirements. This tends to limit the extent and effectiveness of a zoning change. Pre-existing uses and structures may be required to meet new zoning when altered or expanded, depending on the requirements of the local zoning. Districts of Critical Planning Concern (DCPCs), authorized by the Cape Cod Commission Act, can eliminate the legal protections for pre-existing uses, structures and subdivision plans conferred under Chapter 40A.

OVERLAY DISTRICTS

The overlay district is a zoning tool that can be used for growth management. An overlay district lies "on top" of one or more zoning districts and establishes an area where certain growth opportunities or limitations are in effect. In addition to the dimensional and use limitations established by zoning, the overlay district can apply water quality standards for the purposes of drinking water protection or coastal water quality protection, or can identify economic development zones or growth incentive zones based on the presence of infrastructure or other features designed to support dense economic activity. Overlay districts also can be established for other specialized uses such as wireless towers, adult entertainment or medical marijuana.

On the Cape, most towns have adopted overlay districts to support resource protection. Examples include groundwater protection districts, floodplain districts, wildlife corridors, and coastal pond protection districts. Overlay districts can include additional permitting or review requirements, stricter performance standards, or outright prohibition of certain activities (i.e. use of hazardous materials). Several towns have also adopted overlay districts to support growth, including village center districts, revitalization districts, and growth incentive zones. Standards in these kinds of districts may require specific design features or amenities in exchange for allowing for increased density and flexibility in the dimensional requirements and mix of uses allowed.

DISTRICTS OF CRITICAL PLANNING CONCERN (DCPC)

As noted above, the DCPC is a powerful planning and regulatory tool that has been used by Cape communities to manage growth and protect sensitive resources. To date, a total of nine local DCPCs and two Cape-wide DCPCs have been designated with either implementing regulations or other regulations adopted by the towns or the Commission. A complete list of designated DCPCs is available in Appendix 7A.

The following are a few examples of DCPCs that have been adopted for growth management purposes.

- Brewster Water Protection DCPC: designated in July 2008 to protect "zones of contribution" (or watersheds) to public drinking water wells. The DCPC encompasses 6,538 acres in several areas: one in the southeastern part of Brewster, another in the southwestern part of town, and all land in Brewster that is within the Pleasant Bay Water Recharge Area. The DCPC has two purposes: a water resources district and a major public investment district. Watersheds within the DCPC include wellhead-protection lands for public wells in Brewster and for wells in Orleans, Harwich and Dennis. The four Brewster wells in the DCPC provide about 95% of the town's public water supply, and the remaining need is met mostly from private wells. Brewster has invested millions of dollars in the development and protection of the public drinking water supply wells within the DCPC. The Cape Cod Commission approved the town's proposed implementing regulations on October 1, 2009.

- Six Ponds DCPC (Harwich): designated in May 2000 to protect the water and natural resources and to manage growth over more than 1,200 acres of land and 110 acres of water in northeastern Harwich.
- Three Ponds DCPC (Sandwich): designated in February 2000 to protect water quality, preserve open space, and maintain the character of nearly 700 acres of land and more than 300 acres of water in southeastern Sandwich, this DCPC resulted in a reduction of residential development potential.

While prior district nominations have focused on natural resource protection, there are a variety of ways in which DCPCs may be instrumental in coordinating land use goals with infrastructure development to carry out local and regional goals. Reasons for potential DCPC designations might include:

- Coordination of major capital public facilities or areas of public investment,
- Economic development,
- Protection of cultural, scientific and recreational resources or,
- Natural resource protection.

A DCPC nomination may invoke a one year (18 months with extension) moratorium on the issuance of specified local permits within the nominated areas, thus providing a planning window to develop plans and regulations to meet community goals. Materials related to the process for establishing a DCPC are available in Appendix 7B.

There have been two Cape-wide Districts of Critical Planning Concern (DCPCs) designated to enhance the jurisdiction of Cape Cod communities. In response to the enactment of Chapter 262 of the Acts of 2012, Barnstable County established the Fertilizer Management DCPC by ordinance in September 2013. Chapter 262 of the Acts of 2012 vested exclusive authority over nutrient regulation in the Commonwealth (including regulation over fertilizer use and application) to the Massachusetts Department of Agricultural Resources (MDAR). The law contained certain exceptions to MDAR's exclusive jurisdiction, such as regulation adopted pursuant to the Cape Cod Commission Act. Development of the Cape Cod Pesticide and Fertilizer Use Inventory (see Appendix 7C) supported the need for special regulation in Barnstable County to protect Cape Cod's unique water resources. The Fertilizer DCPC designation allows towns to adopt and administer local turf fertilizer regulations.

The enactment of the Oceans Act of 2008, where the state legislature established the need for a state-wide ocean management plan, also inspired Barnstable County government to employ the DCPC tool to preserve jurisdiction and local control of our ocean resources. Barnstable County established the Ocean Management Planning DCPC in April of 2010, and the Cape Cod Commission adopted the Cape Cod Ocean Management Plan (CCOMP) in October 2011 (available at http://www.capecodcommission.org/ccomp). The CCOMP establishes goals, policies and actions to ensure protection of important natural, cultural and scenic resources in balance with certain limited development activities in the ocean.

Later, Barnstable County government adopted regulations in the RPP, consistent with the DCPC purpose, to address off-shore sand mining and cable installations.

NATURAL RESOURCE PROTECTION ZONING

Natural Resource Protection Zoning (NRPZ) is a relatively new form of zoning that has been adopted in several towns in Massachusetts since 2009. It is a variation of a clustered subdivision, but with several enhancements. NRPZ preserves large areas of open space, concentrating all development in a small area. The number of allowed dwelling units is determined by a calculation that first eliminates the amount of important natural resource lands from the determination of the number of allowed units. The net acreage is then divided by the base density to determine the number of units. The base density is generally the same as allowed by the underlying zoning, but the number of units can be increased if the development includes public benefits such as affordable housing, wastewater treatment for the development itself as well as for other units, preservation of farmland, and other benefits to the larger community.

BULK AND BUILDING FORM REGULATIONS

Bulk and building-form regulations, also known as dimensional requirements, include lot size and coverage, building height and setbacks (or build-to lines). Towns can alter these regulations to encourage additional growth in a town center by relaxing height, lot coverage and/or

setback requirements. Conversely, towns can discourage future growth or redevelopment in other areas by tightening dimensional regulations.

Community character can be negatively impacted when small lots (6,000 square feet or less) are connected to wastewater treatment. Due to the size of these lots, removal of Title 5 setback requirements can create development options that are substantially different from limitations imposed by Title 5 (as shown in **Figure 7-2**). Towns should examine lot line setback requirements for small lots if they wish to limit the significant expansion of existing development on small lots. A more detailed discussion of these impacts is provided in the report entitled Sewers and Smart Growth: Challenges, Opportunities and Strategies (Ridley & Associates, Inc. 2009).

USE-RELATED REGULATIONS

Use regulations specify both the kind and intensity of activities that can take place on a given parcel. In communities seeking to promote a vibrant town center, a mix of residential and commercial uses can be allowed through modifications to use-related zoning provisions. This kind of regulation can also be used to encourage or restrict intensity of uses, depending upon the desired outcome.

TOWN CENTER ZONING

It has been difficult to invigorate traditional town centers on Cape Cod due to the lack of adequate wastewater infrastructure to support dense development, and zoning bylaws that were set in place decades ago did not support dense, compact development patterns. With the advent of sewers and other technologies, communities have an opportunity to rezone villages and town centers where additional growth is desired. Such rezoning can include dimensional standards that increase height and lot coverage and decrease setbacks, requirements to include mixed-use development, and support for public places and other pedestrian amenities, such as parking on the sides and rear of buildings. Rezoning to allow for denser, more compact development patterns may be balanced with other growth management measures outside of these areas to achieve local goals such as limiting sprawl to reduce wastewater infrastructure costs, preserving community character, and in some instances, for demonstrating "flow neutral" land development controls.

PROVINCETOWN GROWTH MANAGEMENT BYLAW

Provincetown adopted a Growth Management Bylaw in 1989. Its purpose is "both to maintain a level of development that will meet the needs of its current and future population without overburdening its natural resources or the capacities of public facilities, particularly the provision of potable water, wastewater disposal, and solid waste disposal, and at the same time encourage affordable housing and year-round economic development." The bylaw was adopted more than a decade before the town installed sewers, primarily due to the town's limited potable water supply. The metric for the Growth Management Bylaw is water usage (based on gallons per day Title 5 design flow), but it provides a model zoning (or other regulatory) framework for prioritizing future growth based on resource carrying capacity and for structuring permit allocation to encourage priority uses.

The bylaw limits new growth and expansion based on Title 5 flow. Applicants proposing development (new construction, expansion, change of use) that would result in an increase in Title 5 flow over the existing use must obtain a growth management "allocation permit." The permits are issued in accordance with Table of Use Categories and Priorities that establishes the order for how the pool of available gallons shall be allocated among different uses. The bylaw assigns a gallonage available to each category and the annual process for re-allocation of unused gallons within the use table. Applicants must "get in the queue" for an allocation permit if all available gallons for a particular use have been allocated for the year. The bylaw requires the town manager to provide an annual growth management report that reviews the year's gallonage allocations (as well as overall water usage and solid waste disposal data). Based on the findings of the report, the Board of Selectmen may revise the gallonage allocations for the upcoming year. Since the bylaw's adoption in 1989, voters at town meeting have approved several amendments and revisions to the mechanics of the bylaw and the priority of uses brought forth by the Planning Board, generally in response to fluctuations in the economy.

SLIDING SCALE LOT COVERAGE

In response to concerns about tear-downs of older homes and subsequent "mansionization," out-of-scale

development within the Cape Cod National Seashore, the town of Wellfleet adopted a zoning bylaw that limits lot coverage allowances based on a sliding scale. It provides a higher percentage coverage allowance for smaller lots, which decreases gradually as lot size increases. The bylaw also provides site plan review criteria and special permit review requirements for higher lot coverage.

The town of Barnstable adopted a similar type of sliding scale lot coverage limitation in the Craigville Beach district as part of the Craigville Beach DCPC implementing regulations. See previous discussion on DCPCs for more information.

The town of Provincetown also has a "scale bylaw" that is intended to preserve the existing scale of buildings in a neighborhood. It is an unusual example of a zoning bylaw that addresses and limits building volume. The intent of the bylaw is to preserve existing building scale by requiring all new structures and additions to comply with "appropriate" neighborhood scale. The Zoning Enforcement Officer directs the determination of each building's scale/volume based on a methodology set forth in the bylaw and calculates an average neighborhood scale. New structures and additions are limited to an increase/deviation from average scale of 25% or 15% within the historic district unless granted a special permit to exceed the allowance.

PAYING FOR NEW GROWTH

IMPACT FEES

An impact fee is a growth management tool used to help pay for the expansion of public infrastructure by requiring developers to pay their proportionate share of the costs. They are intended to help ensure that there is an adequate availability of public facilities and facilitate fiscally responsible growth. Usually charged when the occupancy permit is issued, impact fees can only be used to help offset the costs associated with that particular development. The funds cannot be charged to correct existing deficiencies in public facilities in the community at large.

The Section 208 Plan Update suggests that nitrogen budgets could be developed to better explain nitrogen cycling on Cape Cod. The following are suggested for inclusion:

- Nitrogen content in precipitation
- Watershed attenuation/denitrification
- Nitrogen loads to estuaries
- Food imports
- Fertilizer imports
- Atmospheric deposition

A comparison could be made between the existing nitrogen budget and a pre-development nitrogen budget to identify how nitrogen imports and natural attenuation capacity have changed over time. This effort would provide an overall picture of nutrient impacts on the region, including, in part, an assessment of nitrogen deposition from environmental and other non-controllable sources and could be used to form the basis for creating an impact fee system.

NITROGEN IMPACT FEES

One way to pay for new growth is through adoption of a nitrogen impact fee program. A nitrogen impact fee is a monetary charge imposed by a local government on new developments to recoup or offset a proportionate share of public costs associated with mitigating nitrogen pollution caused by that new development. In other words, a nitrogen impact fee shifts some portion of the financial burden to mitigate new nitrogen contributions from the public to the private sector. Impact fees take into account the direct capital costs required to accommodate new developments with wastewater infrastructure and, to the extent measurable, the costs of other negative consequences borne by the public. The result is to incorporate the full social and environmental costs of new development into the impact fee.

To withstand judicial scrutiny, impact fee systems must establish a rational nexus between the impact caused by the new development and the fee imposed to mitigate that impact. The Section 208 Plan Update sets forth the following guiding principles for establishing a nitrogen impact fee system:

- Any nitrogen impact fee must be based on the amount of nitrogen discharged from a property and any costs associated with mitigating its effects. Based on available data, it is possible to formulate

an equation that calculates nitrogen output by parcel by combining wastewater flow and lawn fertilizer run-off. Given existing state and federal statutes and recent legal challenges, the envisioned system would be best served by imposing a fee as a direct function of a parcel's nitrogen discharge, satisfying both "nexus" and "rough proportionality" standards of the courts (Koontz v. St. John's River Water Management District, 133 S. Ct. 2586 (2013)).

- Nitrogen pollution damages the environment and social welfare as a whole and its remediation increases infrastructure costs. To be fully effective, a nitrogen impact fee system should cover both direct and indirect costs, quantified in a manner that establishes a rational "nexus" for nitrogen output from development. An incentive system that does not account for the full cost of development could unintentionally incentivize over-development and consequently irreparably damage the environment and society (Rosenberg 2003).
- A nitrogen impact fee system should incentivize commercial and residential development and redevelopment in designated areas for growth based on community vision mapping process, and only in nitrogen sensitive areas with adequate wastewater infrastructure.
- The fee system needs to contain waivers based on affordability and monetary incentives for adoption of nitrogen-reducing technologies in new developments.

Nitrogen impact fees can be adopted by towns or on a regional level.

Cape Cod's current development incentive structure will continue to lead to over-development and degraded water quality from nitrogen pollution. Realigning development incentives, particularly through the use of nitrogen impact fees, can begin to remedy this situation.

Cape Cod towns make their own decisions about how much development to allow by adopting zoning and other land use regulations. To the extent that development has occurred or continues to occur without the benefit of wastewater treatment, there is a development threshold above which nitrogen harms the region's beaches and other tourist attractions. The region as a whole is dependent on tourism and recreational ecosystem services. Each town's individual development decision impacts not only its neighbors, but the long-term viability of the region. If a town allows unmitigated development, it receives a private benefit in the short-term by externalizing costs, such as nitrogen pollution, onto other towns in the region. In this situation, the long-term viability of the town and the region will be threatened by the degradation of the Cape's environment. In the long-term, limited development and the provision of wastewater infrastructure will maximize economic benefits for all towns.

A nitrogen impact fee system aims to include the complete social and environmental cost of a development into the developer's project cost, neutralizing private short-term benefits at the expense of long-term public costs. Several states are testing elements of a region-wide impact fee system. Eighteen states have implemented or intend to adopt variations of an impact fee for harmful externalities as part their growth management strategy. In addition, a form of "nutrient trading" is being considered for the Chesapeake Bay watershed, which includes portions of New York, Pennsylvania, Maryland, Virginia, West Virginia, Delaware, and Washington D.C. Lessons from these prior approaches have varying degrees of relevance and can be informative in future discussions across the Cape about nitrogen impact fee systems.

The next step in exploring the viability of implementing nitrogen impact fees is a discussion with Cape officials and stakeholders about the benefits and drawbacks of instituting local and/or Cape-wide nitrogen impact fees.

TAX INCREMENT FINANCING

Tax increment financing (TIF) creates a redevelopment district in which infrastructure improvements and/or project developments are financed based upon an anticipated future increase in property values. The idea is that the development improvements will eventually result in higher property taxes and therefore the financing "increment" is justified. TIF can be initiated either by a private developer or the municipality itself. Once the redevelopment district is determined, a base property value assessment is performed, and the revenue to agencies other than the redevelopment authority is "fixed" at a present-day amount. Any increase in tax revenue through increase in property value will accrue to the redevelopment authority. The TIF district is created for a set time period, usually between five and 30 years, and once the time period

ends, the increase in revenue from the property value increase reverts to the baseline taxing structure. For more information visit: https://www.planning.org/divisions/planningandlaw/propertytopics.htm.

TRANSFER OF DEVELOPMENT RIGHTS

Transfer of Development Rights (TDR) is a market tool communities can use to achieve land preservation. The preservation is accomplished by allowing one landowner to sever his/her development rights in exchange for compensation from another landowner who wants his/her development rights to increase. TDR programs transfer the development rights of a predetermined lot , known as a sending area, to another lot , known as the receiving area. Thus, while the development rights are reduced or severed on the sending area, increased density and development is allowed on the receiving area. The sending sites are typically deed-restricted so that only appropriate uses are allowed from the rights sale onward. TDR programs can be mandatory or voluntary. With mandatory TDR programs, the sending and receiving areas are pre-designated by downzoning the sending areas and decreasing the base density of the receiving areas so more development rights must be purchased in order to build at higher densities. With voluntary TDR programs, the sending areas are not downzoned. Instead, owners retain the option to receive payment for development on their property; these transferred rights are known as development credits. For more information visit: https://www.planning.org/divisions/planningandlaw/propertytopics.htm.

NUTRIENT REDUCING DEVELOPMENT

The development or redevelopment of property provides an opportunity to address wastewater treatment for the particular parcel under development, as well as the wastewater treatment needs of surrounding development. This solution removes both the new nitrogen generated by the new development and the existing nitrogen generated by existing proximate development, so that a net nitrogen reduction is realized in the area. This model can also be applied to existing developments, where one existing development has excess treatment and disposal capacity and allows another existing development to connect to their underutilized wastewater treatment infrastructure.

Two example projects that have been permitted on Cape Cod are Willowbend (Mashpee) and Red Brook Harborview (Bourne). The Willowbend project entailed construction of a nine-hole golf course expansion on Shoestring Bay. In addition to using an Integrated Pest Management Plan to minimize the use of fertilizers and chemicals, the project provided a nitrogen loading offset by connecting the neighboring Cotuit Bay Condominiums to the Willowbend Wastewater Treatment Plant. Willowbend paid for and constructed the sewer connection at no cost to the Cotuit Bay Condominiums resulting in a net reduction of 1,274 pounds of nitrogen per year to Shoestring Bay.

The Red Brook Harborview project is a mixed-use (residential and commercial) project that provides a village-scale wastewater treatment plant located on Red Brook Harbor in Bourne and was enabled by the Marine Commercial Overlay District zoning amendment. The bylaw allowed an increase in density (from four to 15 residential units) in exchange for an advanced wastewater treatment plant. The plant was oversized to treat wastewater from the adjacent Kingman Yacht Center, the 15 townhomes and up to 52 existing single family homes in the Cedar Point neighborhood. Upon buildout the project will result in a net reduction of 2,468 pounds of nitrogen per year to Red Brook Harbor. The wastewater treatment plant will be constructed and paid for by the private developer and made available to the neighborhood residents.

In general, the costs of this solution will be variable according to the technology employed. The cost to all involved parties will likely be reduced in relation to construction of separate, independent wastewater treatment works, by spreading the cost across more users in close proximity.

The performance and potential challenges of this approach will depend on the technology employed. In the past this approach has been employed by commercial development utilizing traditional infrastructure that has excess capacity to cover other new or existing development. Maintenance and monitoring responsibilities are typically established through private contractual agreements.

The benefit of this solution is the net nitrogen reduction in an area that is experiencing beneficial growth and development. The greatest challenge is that, under current regulations, this approach to addressing impacts from new development is voluntary and could be more complicated than addressing the on-site nitrogen generated by the new development. In order for this approach to be widely

used, incentives within the regulations would need to be developed. These could include density bonuses or reductions in other mitigation costs for non-nitrogen impacts. Current potential permitting agencies include: MassDEP, local departments of public works, boards of health, building departments, and the Cape Cod Commission.

The next step in exploring this approach is to initiate a discussion with Cape officials and stakeholders regarding potential regulatory amendments to promote sharing of private wastewater infrastructure to achieve net nitrogen reductions in nitrogen sensitive watersheds.

Planning Partnerships

Cape Cod is greater than the sum of its 15 towns. Because Wastewater Management Agencies will need physical domain over the lands and nutrient contributions they seek to manage, coordination with federal and state partners will be necessary to achieve water quality goals. Joint Base Cape Cod and the Cape Cod National Seashore are the largest of these state and federal land holdings, and they provide important open space and significantly reduced residential density and related nitrogen loads within their borders.

The Massachusetts Department of Transportation (MassDOT) state roadway system impacts coastal and freshwater bodies through stormwater runoff and tidal restrictions caused by state roadway bridge abutments and there is an opportunity to work cooperatively to address these issues. Federal, state and municipal governments and local land trusts play an important role through past and future open space acquisitions that prevent new development and protect water resources (see open space protection section above). Various federal and state programs are also available to assist the region as we implement water quality restoration measures.

JOINT BASE CAPE COD

RELATIONSHIP TO SURROUNDING TOWNS

At approximately 22,000 acres, Joint Base Cape Cod (JBCC), formerly known as the Massachusetts Military Reservation (MMR), is one of the largest contiguous properties in state or federal ownership on Cape Cod. There are four military commands operating on the base, including: the Massachusetts Army National Guard at Camp Edwards, the Massachusetts Air National Guard's 102 Intelligence Wing at Otis Air National Guard Base, the 6th Space Warning Squadron phased array radar site at Cape Cod Air Force Station, and the U.S. Coast Guard at Air Station Cape Cod.

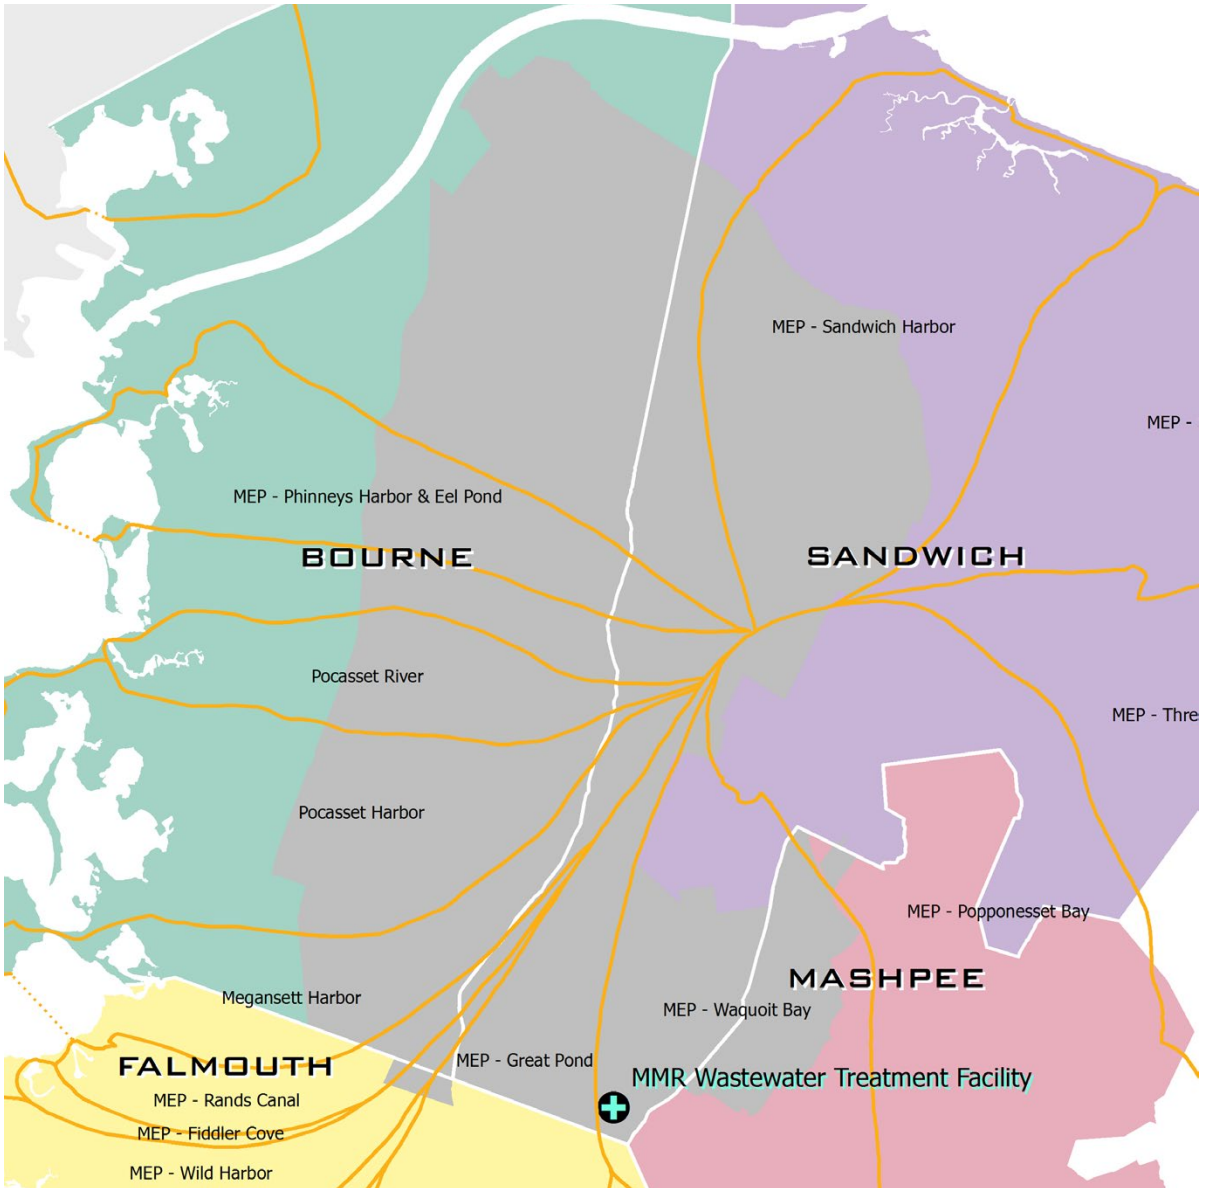
Camp Edwards, principally used for Army National Guard training, is comprised of approximately 15,000 acres in the northern portion of the base. The cantonment area, which is substantially more developed with structures, roads and other infrastructure, is comprised of approximately 7,000 acres in the southern portion of the base. JBCC includes parts of the towns of Bourne, Mashpee, and Sandwich, and abuts the town of Falmouth in Barnstable County, Massachusetts. The northern 15,000 acres of the base, also called the Upper Cape Water Supply Reserve, where the majority of the Army National Guard training occurs, was protected through a Memorandum of Agreement (MOA) and an Executive Order in 2001. The MOA was codified into law in 2002. Activities in the Reserve are subject to Environmental Performance Standards that were enacted to ensure the permanent protection of the Cape's drinking water supply and wildlife habitat in that area (Harshbarger 1998). The Environmental Management Commission ("EMC") of the JBCC consists of three members: The Commissioner of the Department of Fish and Game, the Commissioner of the Department of Conservation and Recreation, and the Commissioner of the Department of Environmental Protection. The EMC's responsibility is to ensure the permanent protection of the drinking water supply and wildlife habitat of the Reserve and to ensure all military and other activities in those 15,000 acres are consistent with the Environmental Performance Standards. The northern 15,000 acres contains four public water supply wells, three as part of the Upper Cape Regional Water Supply Cooperative and one as part of the Bourne Water District. The EMC is assisted by the Community Advisory Council ("CAC"), which consists of the following members: one each from Falmouth, Bourne, Sandwich and Mashpee; one family member resident of the JBCC; two representatives from the military; one from the Cape Cod Commission; one from the Wampanoag Tribe; one from the Upper Cape Regional Water Supply Cooperative; and five other at-large members. All members are appointed by the Governor.

STATUS OF JBCC WASTEWATER TREATMENT FACILITY

The 102nd IW is the host for utilities at JBCC, including the wastewater treatment plant (WWTP). Massachusetts DEP issued the 102nd IW a new discharge permit early in 2004 that authorizes an average 360,000-gallon per day discharge from the WWTP to enable it to accept a maximum 60,000-gallon per day sewage discharge from the new Barnstable County Jail and House of Corrections just north of Connery Avenue, in addition to wastewater from military installations. The location of the treatment facility is shown in **Figure 7-4**.

The MAARNG operates two facilities in the Reserve (Camp Edwards) with individual septic systems: Range Control and the Ammunition Supply Point (ASP). The US Air Force's Cape Cod Air Force Station also operates septic systems at their facility within the northern 15,000 acres. These discharges should be quantified and allocated to their appropriate watersheds.

The status of the 102nd's wastewater treatment plant is based in part on information contained in Appraisal Consulting Services for the Wastewater Treatment System at the MMR (Appraisal) completed in December 2012 by CH2MHill for MassDevelopment, a quasi-public state financing and development agency for the Commonwealth. Additional information was obtained from CWMPs either completed or currently in process by the four Upper Cape towns.



Joint Base Cape Cod, Surrounding Towns and Location of Wastewater Treatment Facility

Figure 7-4

The wastewater management system at JBCC was designed to provide wastewater collection, onsite treatment, and onsite disposal of treated wastewater from installation facilities. Wastewater is collected and conveyed by gravity and force mains to the WWTP located at the southern boundary of the base. Treated wastewater from the onsite WWTP is pumped through a 10.5 mile long effluent force main and disposed through rapid infiltration beds (RIBs), which are located on the northern boundary of the installation. The effluent force main and the disposal beds were constructed in 1996. The system was originally designed to allow biosolids from the WWTP to be composted and disposed of onsite as a soil amendment. Currently, wet biosolids are trucked offsite for disposal.

The general condition of the wastewater treatment plant was found by the CH2MHill report to be "fair" since it was upgraded in 1996 and underwent a number of part replacements in 2002. The report also noted the condition of the collection system was "cautious" since the collection system is over 50+ years old and no formal assessments have been completed. A 2001 inflow and infiltration study (I/I) indicated that I/I was a significant portion of the flow captured by the system.

The study reported that the replacement cost was $44 million, but that the replacement cost less depreciation was $16 million. The near-term and 20-year needs for JBCC users were reported as 140,000 and 147,000 gallons per day (gpd) respectively.

The study attempted to gauge the wastewater needs of the surrounding communities. This effort made use of the best available information from the towns to reflect existing and potential wastewater needs. The total short-term and future needs for treatment and total disposal are indicated in **Table 7-1** (excerpted from the study). Since the completion of the 2012 Appraisal, the Town of Mashpee filed a draft CWMP with the Massachusetts Environmental Policy Act (MEPA) Unit indicating a potential for treatment and disposal of 200,000 gpd of wastewater generated in the western portion of the town to be transported to and treated at the 102ndIW's WWTP.

ENTITY	NEAR-TERM NEEDS (GPD)	20-YEAR NEEDS (GPD)	REQUIREMENTS
JBCC Users	140,040	147,300	Treatment and Disposal
Town of Falmouth	200,000	200,000	Disposal only
Bourne Landfill	40,000	80,000	Disposal only
Town of Bourne	0	1,836,000	Treatment and Disposal
Town of Sandwich	156,000	630,000	Treatment and Disposal
Town of Mashpee	158,000	658,600	Treatment and Disposal
Total: Treatment and Disposal	454,040	3,271,900	
Total: Disposal Only	240,000	280,000	

Summary of Wastewater Treatment and Disposal Needs

Table 7-1

STATUS OF DISPOSAL SITE

Final treated effluent is pumped through a 10.5-mile ductile iron force main to four sand-lined RIBs located on the northern boundary of the JBCC south of Route 6 (Sandwich Road).

The effluent disposal system consists of the following components:

- Piping to distribute effluent to RIBs
- Four sand lined RIBs that cover approximately six acres
- Seven groundwater monitoring wells (three pairs downgradient, one upgradient)

The soil characteristics and design parameters for the treated wastewater disposal system are described in the Hydrogeologic Investigation and Design Effluent Infiltration Basins technical memorandum (CDM Smith 1993). Review of the hydrologic analysis indicates that the design capacity of the RIBs, according to Massachusetts Department of Environmental Protection (MassDEP) criteria, is substantially higher than the permitted flow to the WWTP. Based on the size of each infiltration basin and an assumed hydraulic conductivity that is typical of the Cape, the total

capacity of the four RIBs is approximately 907,000 gpd. With one RIB as reserve capacity, the disposal capacity is about 672,000 gpd.

JBCC JOINT LAND USE STUDY

The Cape Cod Commission completed an update to a 2005 JBCC Joint Land Use Study (JLUS) in October, 2013. Factors prompting the Army's re-nomination of JBCC for a JLUS were changes to missions on the installation due to the 2005 Base Realignment and Closure (BRAC) round, an increase in the training population using JBCC's ranges, and concern about the compatibility of future civilian land uses surrounding JBCC.

As demonstrated in the Appraisal discussed above, the WWTP and RIBs have sufficient capacity for existing and future (20-years) JBCC military wastewater needs. Those facilities also have excess capacity to treat and dispose of wastewater generated by non-military entities. Through the JLUS process, and based on the Appraisal, the JLUS identified the potential for a military/municipal partnership and shared services through municipal use of the excess capacity of the JBCC WWTP and RIBs for wastewater and landfill leachate disposal. The JLUS states:

Given the wastewater nutrient management needs of the region to achieve TMDL compliance and limited wastewater infrastructure on Cape Cod, it is a recommendation of this plan that existing capacity at the JBCC WWTP should be reserved for military and community needs.

The Office of Economic Adjustment (OEA), US Department of Defense provided funding for the JLUS update and provides funding for studies and preliminary design for potential shared infrastructure and services between military bases and surrounding communities.

JBCC MILITARY AND NON-MILITARY NITROGEN CONTRIBUTIONS

As stated above, there is sufficient wastewater treatment and disposal capacity for existing and future (20-years) military needs. The JBCC controls land within 13 watersheds that are shared with the towns of Bourne, Sandwich, Falmouth and Mashpee, as shown previously in **Figure 7-2**. The individual municipalities are responsible for planning and implementation to prevent violations of the Federal Clean Water Act. Because the JBCC controls land within watersheds that are shared with the towns, increases in the contribution of nitrogen from the JBCC within those watersheds will raise the bar for towns striving to meet TMDLs, and potentially increase the burden on municipal taxpayers.

While there is adequate treatment and disposal capacity for military uses, an unknown level of nitrogen contribution could result from non-military uses on the base. MassDevelopment has expressed an interest in promoting new development on the base with uses that do not compete with municipal economic development opportunities, and which are military-compatible. With these two caveats, this Plan supports the creation of new non-military uses that have proper wastewater treatment and disposal to ensure no net nitrogen impacts in nitrogen sensitive embayments.

To ensure equity and parity between the base and the surrounding towns, this Plan proposes further discussion and coordination between JBCC leadership, MassDevelopment and the Commission to establish a wastewater allocation policy for land uses within nitrogen sensitive watersheds that emanate from the base. Further, the military should ensure that future development within the cantonment area be connected to the JBCC wastewater treatment plant wherever feasible as recommended by the 2005 JLUS. Future agreements could also establish a protocol for allocating excess capacity at the WWTP and RIBs. The Commission is currently working to establish a new, proactive communications plan between the JBCC, MassDevelopment, the Commission, and the surrounding towns through a grant provided by OEA. The Commission has a webpage that provides comprehensive information on current and past plans and studies completed by the Commission regarding the JBCC, including the 2005 Joint Land Use Study and its 2013 update, as well as the MMR Master Plan Final Report, which includes background information on past environmental issues that led to subsequent planning processes. For more information, visit www.capecodcommission.org/jbcc.

Recommendation S7.1: The Cape Cod Commission shall continue discussion and coordination with JBCC and MassDevelopment regarding wastewater allocation policy for the base.

Recommendation S7.2: The Military should ensure that future development within the cantonment area be connected to the JBCC wastewater treatment plant wherever feasible.

STATE HIGHWAYS

STORMWATER MANAGEMENT

79% of the Cape's land mass is in a watershed to a coastal embayment. It is therefore not surprising that miles of municipal and state roadway run through nutrient impaired watersheds on Cape Cod (see **Figure 3-1** in Chapter 3). To varying degrees, stormwater runoff from these roadways contributes to the nutrient problems experienced on the Cape.

Through the MassDOT Impaired Waters Program (IWP), MassDOT has instituted a program to address roadway stormwater runoff draining to impaired water bodies. The program is part of the agency's compliance with its NPDES Phase II Small MS4 General Permit and commitments in an EPA enforcement letter dated April 22, 2010. Under the Program, "Impaired" water bodies are those listed as Category 4a or 5 in MassDEP's Integrated List of Waters (often referred to as the 303(d) list).

As currently proposed, MassDOT's IWP will include a methodology to assess water bodies covered by a nitrogen TMDL on the Cape. MassDOT is in the process of developing a methodology to assess stormwater contributions. This Section 208 Plan Update recommends future coordination of these assessment methodologies between MassDOT and the Commission.

Recommendation I7.3: MassDOT and the Cape Cod Commission should coordinate the methodologies for assessing stormwater contributions.

The Commission will review and comment on future NPDES regulatory filings and work with US EPA Region 1 regarding IWP methodologies adopted for the Cape. Due to the geology and hydrology of the Cape, it is recommended that Cape-specific Best Management Practices (BMPs) be developed for stormwater management in nutrient sensitive watersheds. Further discussion of specifically identified direct and indirect stormwater discharges to impaired water bodies is also recommended.

TIDAL RESTRICTION

Another area of cooperation is in the widening of coastal bridge abutments to improve tidal flushing in coastal areas where it is feasible and practical during roadway improvement projects. For example, MassDOT is proposing to replace an existing bridge over the Bass River between the Towns of Dennis and Yarmouth, associated with the Cape Cod Rail Trail extension. The existing bridge abutments constrict flow of the Bass River and are listed as a tidal restriction by the Cape Cod Atlas of Tidally Restricted Salt Marshes. The currently proposed bridge would increase the bridge opening to match upstream restrictions and would provide improvements to the hydraulics in the channel by increasing tidal flushing, decreasing channel velocities, and decreasing scour potential. Another example is the widening of the Muddy Creek bridge which is currently being undertaken by the towns of Harwich and Chatham.

To help address stormwater management issues within state highway layouts on Cape Cod, this Plan recommends the following:

- The Commission should work with the Cape Cod Metropolitan Planning Organization (MPO) to adopt policies that would require to the maximum extent practical design and construction of Cape-specific BMPs in Transportation Improvement Project (TIP) funded roadway improvement projects in the region. The Commission should also work with MassDOT through the IWP to identify Retrofit Projects to address specific roadway runoff issue affecting water quality in the area.
- The Commission should engage in discussions with MassDOT regarding the potential use of the state roadway right-of-way. These rights-of-way may present opportunities to permit, pilot and demonstrate non-traditional nutrient removal/remediation technologies, treated water effluent disposal, and water quality monitoring facilities that may be incorporated into state roadway design or constructed in existing roadway layout.

- The Commission and MassDOT should establish a data-sharing agreement to ensure that the best available infrastructure data is fully accessible to each agency.
- MassDOT should seek easements from public and private entities to accommodate the location, construction and maintenance of nitrogen reducing stormwater infrastructure where limited state road right-of-way would prohibit or complicate such location, construction or maintenance.

This Plan also recommends future coordination between MassDOT and the Cape Cod Commission to:

- Develop methodologies to assess stormwater contributions from state roadways,
- Identify opportunities to widen coastal bridge abutments to improve tidal flushing in coastal areas,
- Pursue improved data sharing between the two agencies.

The Cape Cod Commission will work with MassDOT through its IWP to identify Retrofit Projects to address specific roadway runoff issue affecting water quality. The Cape Cod Commission will comment on future NPDES regulatory filings by MassDOT with US EPA Region 1. Other areas of potential coordination include use of the state roadway rights-of-way for water quality improvement projects, and encouraging the use of easements from public and private entities on lands abutting state roadways to accommodate stormwater management systems.

Coordination between MassDOT and the Cape Cod Commission should be continued.

OTHER REGIONAL/STATEWIDE INITIATIVES

US EPA received $2 million in funding in FY14 to begin implementing the Southeast New England Coastal Watershed Restoration Program (SNEP). SNEP is a partnership among public and private stakeholders collaborating to create a broad ecological and institutional framework for protecting and restoring the coastal and watershed area spanning Westerly, RI to Pleasant Bay, MA. Nutrients, stormwater, and habitat restoration have emerged as key issues for this geographic area, and development of innovative or more effective approaches for managing them is a common priority. Those approaches that integrate habitat and water quality are of particular interest, as are projects that are transferable to the entire Region.

In FY14, the two National Estuary Programs (NEPs) - Narragansett Bay and Buzzards Bay - awarded $723,869 and $728,559, respectively, on behalf of SNEP to provide funding for projects in their study areas. See Chapter 4 for details on the projects that were funded.

The FY15 President's Budget includes additional funding for this Program - a total of $5 million for the region. Continued support for this program will allow Cape Cod communities to explore and pilot the non-traditional technologies and approaches identified in this plan that otherwise may not be possible through traditional local funding and financing. Cape Cod communities will have the opportunity to test the effectiveness of non-traditional technologies and approaches locally, continue refining the Technologies Matrix, and transfer that knowledge to other areas regionally and nationally.

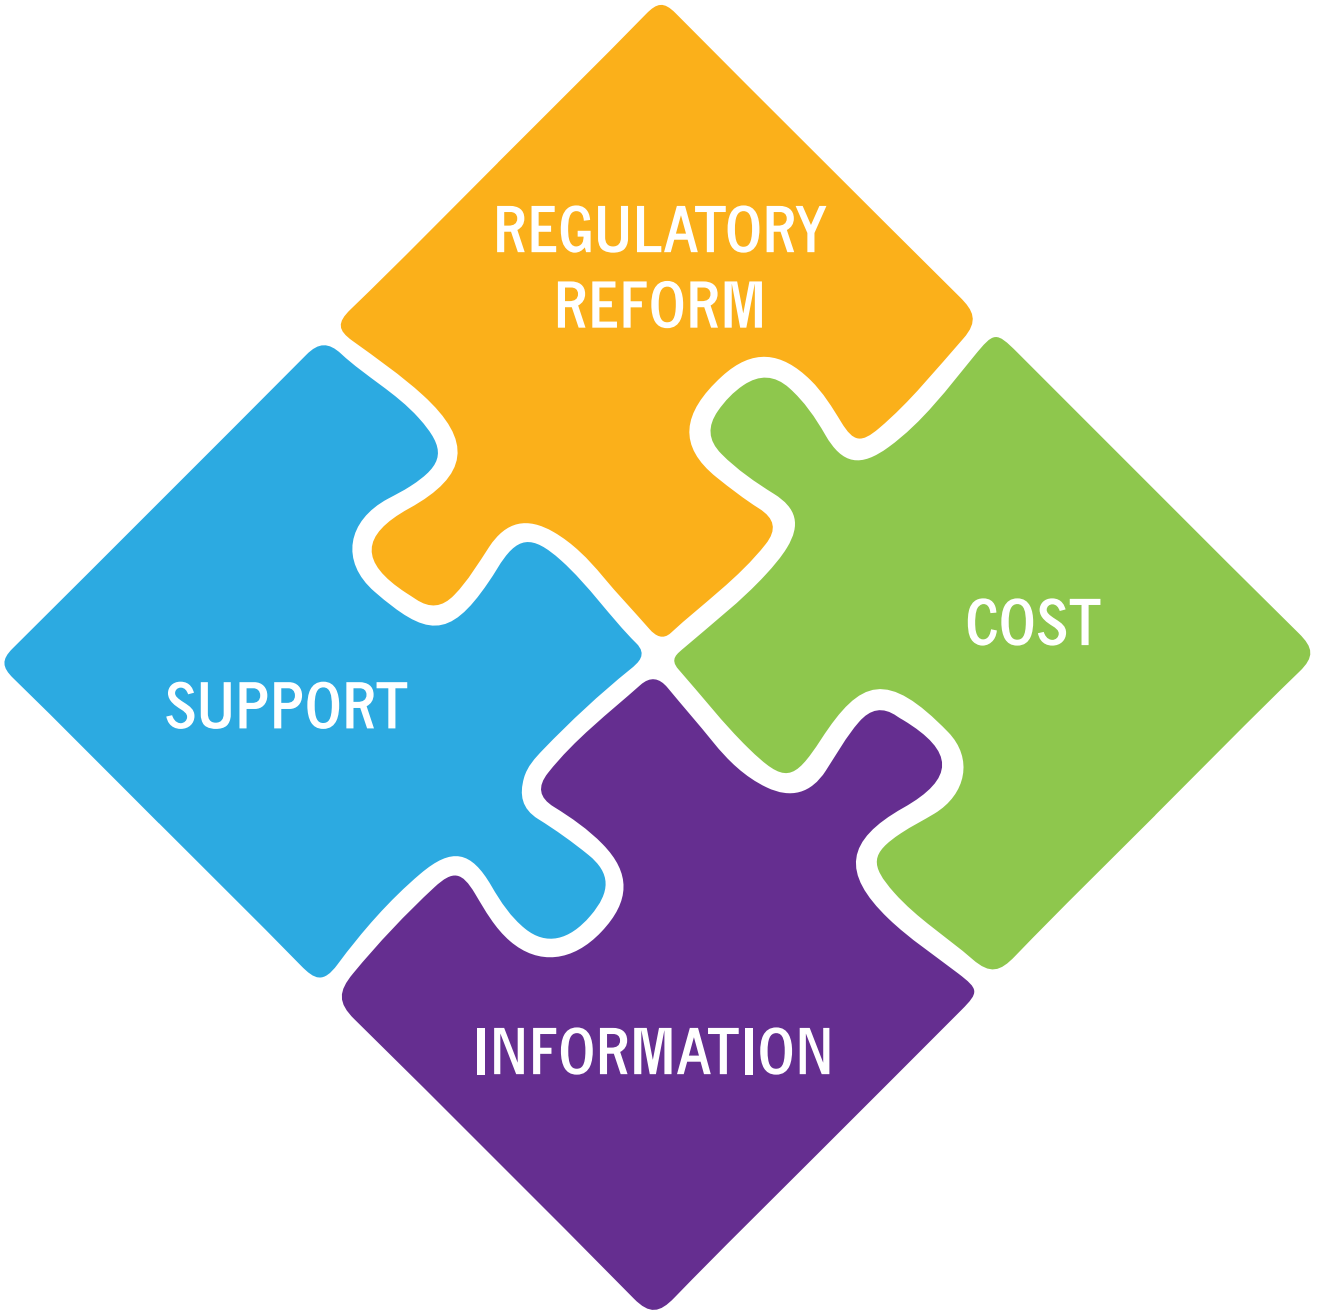
As part of the Section 208 Plan Update, the Commission suggests that US EPA continue its efforts under SNEP and encourage the continued expansion of the program moving forward.

> **Recommendation C7.4: US EPA should continue to expand the efforts of the SNEP program and encourage the continued expansion of the program moving forward.**

08 IMPLEMENTATION

Recommendations

Cape Cod is experiencing a significant decline in our near-shore water quality that threatens not only our environment but also our economy. Many towns have been engaged in this discussion for years but action has been difficult. Regulations that drive and support efforts to solve our nutrient issues are focused on the jurisdiction of political subdivisions instead of the jurisdiction of the problem – watersheds. Available enforcement measures were developed with different pollution problems in mind.



REGULATORY REFORM
COST
SUPPORT
INFORMATION

IMPLEMENTATION

Chapter 8: Recommendations

Without action the future presents Cape Cod with a limited range of possibilities, the extremes of which are equally bad. Do nothing and we threaten our seasonal economy and watch as the property tax burden in every town migrates away from the coast and toward those whom can least afford it, an economic dislocation that will permanently disfigure the region, or wait for court mandated enforcement of currently available regulations that would come at great cost to Cape Cod homeowners and alone would not solve the problem.

The recommendations that follow are the result of 12 months of active community engagement. Collectively they represent a path forward that provides an opportunity to implement a responsible plan for the restoration of the waters that define Cape Cod.

The recommendations presented throughout this Section 208 Plan Update are restated here and grouped in four categories, outlining actions necessary to implement the plan update and restore water quality:

- Information (I)
- Regulatory Reform (R)
- Support (S)
- Cost (C)

Information

The course of action proposed in this document depends on information. The collection of data, the development of tools making data easier to use, and the analysis of water quality and wastewater technologies and policies create the framework for designing responsible watershed plans. The watershed scenarios created by adaptive nutrient management planning are dependent on a regional monitoring program that provides performance monitoring of selected technologies and policies and compliance monitoring measuring the collective effectiveness of permitted watershed nutrient reduction and removal strategies (**Monitoring I4.7**). In order to effectively monitor non-traditional technologies, this plan recommends that the Cape Cod Commission provide a technical guidance document that includes draft monitoring protocols for non-traditional technologies by September 2015 (**Monitoring Protocols I4.8**).

New information and data collected and learned through monitoring and research should be reflected in the Technologies Matrix. This Section 208 Plan Update recommends that the Commission develop a process for annual updates to the Technologies matrix (**Technologies Matrix Updates I4.1**). In addition, the Commission shall seek opportunities to sponsor an annual symposium to present and review new research on nutrient management technologies and approaches that coincides with regular updates to the Technologies Matrix (**Annual Technologies Symposium I4.2**).

The information collected should be housed in a regional water quality data center and made available to the public serving as a primary source for the continued research and development of water technologies and modeling. The creation of a data center will make sure the public is afforded the highest level of transparency regarding the information used as a basis for water quality policy and

associated capital planning (**WQ Data Center I4.10**). This information loop will enhance effective modification of Targeted Watershed Management Plans (TWMPs).

In addition, the Commission shall create a standing Monitoring Committee, to support implementation of the plan and identify and track developing issues, subject to available resources (**Monitoring Committee I4.9**).

This plan update also suggests continued cooperation and coordination with MassDOT in part to develop methodologies to assess stormwater contributions from state roadways, identify opportunities to improve tidal flushing in coastal areas and use rights-of-way for water quality improvement projects (**MassDOT I7.3**).

Lastly, in order to keep costs low and still meet water quality goals, a significant percentage of wastewater generation on Cape Cod will continue to rely on septic systems creating a demand for septage treatment. More information is needed and this report recommends an evaluation of the demands for septage processing and treatment (**Septage Treatment I4.4**).

Regulatory Reform

The existing regulatory framework for wastewater is better suited for permitting traditional facilities and needs to evolve to meet the challenges of diffuse, non-point source nutrient pollution. Changes are necessary to make it easier for communities and to better respond to the problem.

The MEPA process is generally the first hurdle encountered by communities planning wastewater programs requiring SRF funds. Process improvements recommended in this update create a streamlined Special Review Procedure for the review of TWMPs jointly by the Massachusetts Environmental Policy Act (MEPA) unit and the Cape Cod Commission (**SRP R3.6**). Targeted Watershed Management Plans, based on watershed boundaries, should be required. Minimum performance standards and guidance will be drafted and issued pursuant to this update within 90 days of its approval (**Targeted Watershed Management Plan R5.1**).

The Cape Cod Commission Development of Regional Impact review that typically follows the issuance of a MEPA certificate of adequacy from the Secretary of Energy and Environmental Affairs should be reformed, and a simpler and more supportive process to review Capital Developments of Regional Impacts (CDRIs) should be developed (**CDRI R3.5**). Local water quality management plans, and material changes to existing plans will be reviewed to ensure consistency with this update (**208 Plan Update Consistency Review R3.7**). Specific guidance on the consistency review shall be issued by the Commission within 90 days of this plan update approval (**208 Consistency Review Guidance R3.8**).

Additionally the collective responsibility of localities for nutrient loading should be updated and corresponding enforcement actions clarified. This update recommends the Massachusetts Department of Environmental Protection issue guidance outlining the process for watershed permits for nutrient loads (**Watershed Permitting R3.2**). This will allow communities more flexibility in designing efforts to comply with nutrient load limitations defined in the permit.

MassDEP should consider designating Nitrogen Sensitive Areas where watersheds contributing to waterbodies impaired by nitrogen are subject to a 208 Plan, where development primarily relies on septic systems, and/or where the water body is listed on the 303(d) list due to nitrogen overloading, and should modify available remedial actions to allow appropriate time for waste treatment management agencies to plan. (**Nitrogen Sensitive Areas R3.3**). The Commission also recommends that MassDEP eliminate the regulatory language establishing the presumption that Title 5 systems meet the state water quality standards in situations where it has been established that septic systems contribute to non-attainment (**Title 5 Presumption R3.4**). Given the importance of the federal Clean Water Act and the long-term commitment necessary to implement solutions to nutrient pollution on Cape Cod, the Commonwealth should seek delegated authority under the Clean Water Act to issue and enforce NPDES permits (**NPDES Delegated Authority to the State R3.1**).

Support

More direct support of local wastewater planning is warranted. This update recommends that local planning efforts consult with the Commission early in the process to ensure coordination between active watershed planning efforts and the Section 208 Plan Update. The Commission

shall provide technical assistance by assigning Watershed Teams to Waste Management Agencies (WMAs) and municipalities to support community planning efforts and to assist with decision support tools, permitting of technologies and financing (**Watershed Teams S5.3**).

These teams will assist in targeted watershed planning efforts and will advise on the development of watershed scenarios with nutrient management plans consistent with this Section 208 Plan Update (**Hybrid Watershed Planning Approach S5.2**). In conjunction with the watershed team approach, the Cape Cod Commission shall provide a detailed evaluation of effluent disposal options by September 2015 (**Effluent Disposal S4.3**). The watershed plans developed as part of the Section 208 Plan Update will also identify pilot projects and assist in identifying financial resources and direct support through a regional monitoring program. The Cape Cod Commission should establish criteria for eligible pilot projects (**Criteria for Pilot Projects S4.5**). In coordination with The United States Environmental Protection Agency (US EPA) and MassDEP, the Cape Cod Commission shall also work with communities, state and federal agencies to identify opportunities to implement pilot projects in suitable locations across Cape Cod (**Implementing Pilot Projects S4.6**). New development located where it must rely on septic systems should participate in managing nutrient loading. The Cape Cod Commission shall evaluate the steps required for a regional or locally based nitrogen impact fee (**Nitrogen Impact Fee S6.3**).

Additionally, this report recognizes the importance of third-party facilitation of intra and intermunicipal disagreements and recommends a process or guidance to manage disagreement among parties be developed in addition to the allocation of federal, state and regional resources for this purpose (**Managing Disagreement S1.1**). Implementation of the Section 208 Plan Update shall also include a local public participation process that includes efforts specifically designed to reach environmental justice communities (**Environmental Justice S6.6**).

This Plan also proposes further discussion and coordination with JBCC and MassDevelopment (**JBCC S7.1**) regarding wastewater allocation policy for the base, and also suggests that the military ensure that future development within the cantonment area be connected to the JBCC wastewater treatment facility wherever feasible (**Development in Cantonment Area S7.2**).

Cost

This issue of cost is paramount in considering the feasibility of proposed actions to restore Cape Cod's marine water quality. In addition to the existing efforts of the Cape Cod Wastewater Protection Collaborative in working with our legislative delegation to highlight the need for a broader base of financial support for wastewater treatment on Cape Cod, this report recommends that the Cape Cod Commission develop a proposal for a Cape Cod Capital Trust Fund for the financing of infrastructure design and construction (**Cape Cod Capital Trust Fund C6.5**). In addition, this plan recommends that the Cape Cod Commission develop a proposal for a Septic Trust Fund and pursue authorizing legislation (**Septic Trust Fund C6.4**).

Pursuant to the recently signed Water Infrastructure Bill, MassDEP should exercise its discretion in providing principal forgiveness up to 25% (**Principal Forgiveness C6.1**). The Environmental Bond Bill signed by the Governor in August 2014 makes available $4 million for monitoring programs and $4.5 million for pilot projects that are consistent with a current area wide water resource management plan adopted under section 208 of the federal Clean Water Act. This report recommends that the Commonwealth of Massachusetts make these and other funds designated for monitoring programs and pilot projects available to Cape Cod for efforts that are consistent with this Section 208 Plan Update (**Monitoring and Pilot Projects C6.2**). US EPA should also continue to expand the funding and piloting efforts of the Southeast New England Program (SNEP) and encourage the continued expansion of the program (**SNEP C7.4**).

Lastly, local targeted watershed management plans consistent with the Section 208 Plan Update should qualify for existing and potential revenue sources (**Access to Funds C5.4**).

Tools for Collaboration

The subregional stakeholder process associated with the Section 208 Plan Update identified three key categories of challenges to collaboration across town boundaries: who decides, who pays and who manages.

More specifically, "who decides" includes the following questions:

- Who decides which solutions to implement and when and how to reassess?
- How do two or more towns reconcile different levels of planning across town boundaries (including approved CWMPs)?
- How do two or more towns reconcile different town decision-making processes?
- Who decides the timeline required for building agreement?

"Who pays" includes the following questions:

- How do two or more towns coordinate different funding approval processes?
- How do two or more towns apply for and allocate off-Cape funding opportunities?
- How do two or more towns reconcile differences in willingness and abilities to pay?
- Who is financially responsibility for capital funding, operation and maintenance, monitoring, data management, and reporting?

And, "who manages" includes the following questions:

- Who is responsible for preparation of the watershed plan for permitting?
- Who builds, operates, maintains, monitors, and reports?
- Who is ultimately responsible for water quality outcomes?

Included in Appendix 8A is information on existing models that could be used by Cape Cod communities to address the challenges associated with who decides, who pays, and who manages. Existing models include intermunicipal agreements, federal/municipal public/public partnerships, independent water and sewer districts, water pollution abatement districts, districts of critical planning concern, regional health districts, and other potential models. Included is a discussion of the watershed conditions on Cape Cod where each may be most appropriate as a management structure.

Waste Treatment Management Agencies

Section 208 of the Clean Water Act requires the Commonwealth of Massachusetts to designate one or more waste treatment management agencies. As discussed below, these WMAs have specific responsibilities set forth by Section 208(c)(2)(A-I) of the Act, and include.

- to carry out the area wide waste treatment management plan;
- to manage waste treatment works and related facilities;
- directly or by contract, to design and construct new works, and to operate and maintain new and existing works as required by any plan developed pursuant to subsection (b) of this section;
- to accept and utilize grants, or other funds from any source, for waste treatment management purposes;
- to raise revenues, including the assessment of waste treatment charges;
- to incur short- and long-term indebtedness;
- to assure in implementation of an area wide waste treatment management plan that each participating community pays its proportionate share of treatment costs;
- to refuse to receive any wastes from any municipality or subdivision thereof, which does not comply with any provisions of an approved plan under this section applicable to such area; and
- to accept for treatment industrial wastes.

WMAs will need to not only build and operate technologies outlined in their watershed plans to achieve TMDL compliance, but also must have the capacity to issue bonds and notes to raise revenues to carry out their plans.

Given the shared nature of the water resources on Cape Cod, collaboration across town boundaries will be necessary to fulfill the requirements of Section 208.

The March 2015 submission to MassDEP of the Section 208 Plan Update set forth a process designed by the Cape Cod Commission for designating WMAs that included opportunities for local input on establishing responsibility and collaborating on shared watershed scenarios (see box below). See Appendix 8B for documentation of the process. The following amendment to this chapter provides details on the recommended designation and next steps.

DESIGNATING WASTE TREATMENT MANAGEMENT AGENCIES

Each of the 15 Cape Cod towns has been engaged, to varying degrees, in wastewater or watershed planning to date (see Chapter 2). Towns have traditionally been the responsible party for planning, design, construction and management of wastewater infrastructure and these efforts should continue. Each town has the ability to meet the requirements set forth in Section 208(c)(2)(A-I) of the Clean Water Act and are the appropriate entities to develop and implement local decisions regarding technology selection and placement.

WMA Designation Process

The Cape Cod Commission worked with town teams in a working group approach in a series of meetings, between March and June 2015, to get feedback on the designation of waste treatment management agencies (WMAs). Town teams consisted of town managers/administrators, staff, elected officials, and interested citizens. Five watersheds across Cape Cod were used for illustration and discussion around the following topics:

- Principles for establishing allocation of nitrogen responsibility
- Developing watershed scenarios
- Organizational and institutional structures

In June 2015, the Cape Cod Commission amended the 208 Plan Update to include the recommended WMA designations and implementation guidance.

Recommendation R8.1: The Cape Cod Commission recommends the Commonwealth of Massachusetts designate each of the 15 towns in Barnstable County as the WMAs responsible for implementation of the Section 208 Plan Update in the watersheds for which they are responsible.

WMAs are responsible for all of the nitrogen that enters the groundwater from land within their jurisdiction. A process for assigning nitrogen responsibility is described below. Parcels within the jurisdiction of Joint Base Cape Cod or the Cape Cod National Seashore are excluded from the town allocations, unless the parcel is assessed as residential, commercial or industrial.

ALLOCATING NITROGEN RESPONSIBILITY

Assigning Responsibility at the Subembayment Level

The Massachusetts Estuaries Project (MEP) establishes nitrogen thresholds, or the amount of nitrogen a water body can handle and still meet water quality goals, for each subembayment within the larger embayment systems they study. This is the best available information to identify nitrogen reduction targets for specific areas across Cape Cod. Therefore, it is recommended that responsibility for nitrogen reduction be assigned at the subembayment

watershed level. For watersheds that do not have a completed MEP technical report, the entire watershed area should be used.

Stormwater Coefficients

The stormwater coefficients account for driveways, structures, parking lots, and road frontage and the assumptions are as follows:

Residential:

- 2,000 sq. ft. home
- 500 sq. ft. driveway
- 40 ft. (width) road frontage

Non-Residential:

- 15,000 sq. ft. roof
- 30,000 sq. ft. parking lot
- 40 ft. (width) road frontage

Fertilizer Coefficients

The fertilizer coefficients account for lawn area and the assumptions are as follows:

Residential:

- 5,000 sq. ft. lawn

Non-Residential:

- 10,000 sq. ft. lawn

Start with the Unattenuated Controllable Nitrogen Load and Apply Attenuation Factors where Available

The controllable watershed nitrogen load is calculated on a parcel by parcel basis in three parts: wastewater, stormwater, and fertilizer. The wastewater load is calculated based on 90% consumptive use of the water used on each parcel. Nitrogen load from wastewater is calculated by applying the level of treatment associated with each parcel to the wastewater load (for example, septic systems treat to a level of 26.25 parts per million). To calculate both the stormwater and fertilizer loads constant coefficients for each are assigned to every parcel. These assumptions are derived from the MEP process and vary depending on whether the parcel is residential or non-residential. The stormwater and fertilizer coeffficients can be found in the box that follows.

These calculated nitrogen loads are source loads, prior to attenuation in the watershed (unattenuated loads). These unattenuated loads comprise a consistent Cape-wide data set that should be used as the starting point when considering nitrogen responsibility. The MEP technical reports document the ability of ponds and streams to attenuate nitrogen at a subwatershed level, but not all watersheds have the benefit of an MEP report at this time. Wherever a report is available, the attenuation factor should be applied to calculate the controllable load that reaches the water body.

Calculate Responsibility for the Existing Nitrogen Load based on Existing Attenuated Load

Existing attenuated nitrogen load takes into account the best available information without speculating about future development and addresses the problem existing development places on nitrogen overloaded estuaries. Each town's responsibility should be calculated based on its percentage contribution to the subembayment watershed's total controllable nitrogen load. The percentage contribution should be applied to the nitrogen reduction target to calculate the amount of nitrogen, in kilograms per year, for which a town is responsible.

Appendix 8C provides a complete breakdown of subembayment watersheds and nitrogen responsibility by town.

How to Address Growth

As the impact of future growth on attenuation in ponds, streams and other natural surfaces is unknown, projections of future nitrogen load responsibility should be based on unattenuated nitrogen loads.

Future nitrogen load projections are based on a Cape-wide buildout analysis. Future nitrogen responsibility, based on the potential for growth, should be calculated based on each town's potential contribution of nitrogen after buildout.

Data Updates and Local Modifications

The Commission is committed to utilizing the best available data and will update water use data, which is used to calculate wastewater flow and nitrogen load, at the parcel level at regular intervals, likely not to exceed five years. In addition, land use parcel data will also be regularly updated to reflect changes in development. All regular requests and data updates will be completed through the Commission's Strategic Information Office.

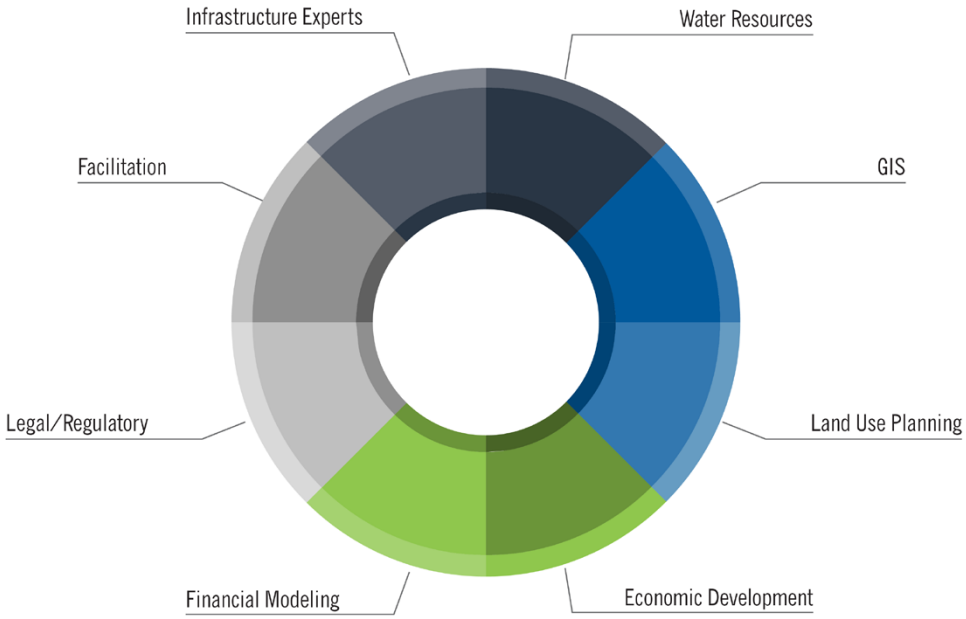
WMAs are encouraged to review the data presented in Appendix 8C and in WatershedMVP. If a WMA has better or more up to date data they will have the opportunity to provide updates to the database. Upon request of a Watershed Team, WMAs can request a data review and update. In addition, data reviews and updates will coincide with the five year incremental reviews associated with the adaptive management plan and the database will be updated as new monitoring data becomes available.

TIMEFRAME FOR IMPLEMENTATION OF THE 208 PLAN UPDATE

Upon certification of the Section 208 Plan Update by the Governor of the Commonwealth of Massachusetts, WMAs will have 12 months to develop "watershed reports" that outline potential scenarios for each of the watersheds for which they are responsible. At a minimum, these reports should include two scenarios that meet water quality goals in the watershed – a collection scenario, which relies completely on traditional collection and treatment, and a non-collection scenario which uses remediation, restoration, and on-site reduction approaches, with little to no collection and treatment.

The collection and non-collection scenarios form the outer bounds of an adaptive management plan. As time and resources allow, WMAs should also work toward establishing a design load that accounts for local non-nitrogen needs and fertilizer and stormwater reduction credits, as appropriate. Once collection and non-collection scenarios and the design load are established, WMAs should begin the development of a hybrid scenario that achieves the design load reduction and incorporates a range of both collection and non-collection technologies. Development of these high level scenarios will assist WMAs in discussions about how they can cooperate with neighboring communities in shared watersheds. A watershed report template is available in Appendix 8D.

In the event that a WMA does not develop a watershed report for a given area the Cape Cod Commission will issue a report based on feedback received in the watershed and



Technical Assistance Available Through Watershed Teams

Figure 8-1

subregional working groups described in Chapter 1 and pursuant to the watershed planning approach identified in Chapter 5. This report will stand as the WMA's plan for that watershed unless and until study is completed by the WMA and an alternate watershed report consistent with this 208 Plan Update is developed by the WMA.

Following this 12 month planning period the Cape Cod Commission will issue an implementation report describing the actions of WMAs to date.

Watershed Teams

The Commission is available to provide assistance to WMAs in developing watershed plans. As part of the process to update the 208 Plan the Commission developed watershed scenarios which will be shared with WMAs. As described in Chapter 5 and in **Figure 8-1**, Watershed Teams are available upon request and can assist WMAs in the areas of water resources, GIS, land use and economic development planning, finance modeling, legal/regulatory issues and consistency, infrastructure and technologies, facilitation, and consensus building. Upon review of the watershed scenarios developed by the Commission, a WMA may request a Watershed Team to assist with modifying the scenarios, as necessary. Specific teams will be provided based on the unique nature of the local planning and the type of assistance required and requested by the WMA.

Watershed Teams can provide training on decision support tools, coordinate local planning efforts with broader regional goals and assist in establishing consistency with local plans and the Section 208 Plan Update. This will be coordinated with the Capital Development of Regional Impact (CDRI) review, as described in Chapter 3, and WMAs that utilize a Watershed Team will receive the benefit of an expedited review based on consistency with the 208 Plan Update.

In watersheds where a Watershed Team is not requested, a 208 Plan Update consistency review in addition to typical regulatory review will be required. Guidance on this process, as described in Chapter 3, will be issued within 90 days of approval of the 208 Plan Update.

Establishing Watershed Associations

Community engagement will help move watershed scenarios, developed as part of the initial 12 month planning period, toward implementation. The process to update the 208 Plan focused on engaging the broader community from the outset, using new decision support tools that make complex data sets easier to understand. This approach involves more people and allows for better discussions and more informed local decisions.

WMAs are encouraged to coordinate with existing watershed associations and/or promote the formation of new associations early in the scenario planning process to ensure public support of the plans during implementation. As described in the proposed Special Review Process outline (Chapter 3) watershed associations might include:

- Elected and appointed municipal officials,
- Members of existing local committees,
- Representatives from the business, real estate, and environmental communities,
- A Cape Cod Commission representative,
- A traditional technology expert,
- A non-traditional technology expert,
- Interested citizens, and
- Representatives from Joint Base Cape Cod and the Cape Cod National Seashore, as appropriate.

These associations can serve as both advisors and ambassadors of local plans. The range of viewpoints represented will ensure closer coordination between plan development, local need and community values. Association members are representatives of the planning process and can share information with their constituents and broader social and professional networks, creating the potential for expanded public support for implementation of a preferred plan when one is established.

Principles for Resource Allocation

Chapter 2 outlines a process for prioritizing watersheds for study. Prioritizing watersheds for resource allocation and implementation requires additional considerations.

Once watershed reports have been developed and adopted by WMAs they should be assessed based on level of community support, including the level of collaboration and cooperation in shared watersheds, the potential for the plan

to facilitate information transfer around new technologies and approaches, estimated time to realize water quality improvements, and ongoing implementation of other capital projects. These considerations should be reviewed in addition to the nitrogen load and degree of impairment in the watershed.

Cost Savings of the 208 Approach

For over a decade Cape Cod towns have been struggling to solve the nitrogen problem and restore the health of our estuaries. Many towns have developed plans to provide wastewater infrastructure to homes and businesses and restore water quality in their embayments but few plans have been implemented. The capital costs of plans for just six of these towns range from $100-$700 million each totaling over $2 billion utilizing infrastructure better suited for urban areas with appropriate density and rate payers. Collectively these plans would remove less than half of the nitrogen necessary to meet water quality standards and do not address many less densely populated and more costly areas of the region.

The Regional Wastewater Management Plan (Cape Cod Commission 2013) estimates that it would cost between $4.2 and $6.2 billion to provide the source reduction necessary to remediate water quality problems in our embayments Cape-wide.

The 208 Plan Update process established an approach more suitable to the largely non-urban and seasonal nature of the communities on Cape Cod. The approach considered remediation and restoration approaches in addition to source reduction. It identified areas with suitable density for collection systems and identified land use characteristics associated with the appropriate use of watershed and embayment technologies, which may be implemented at a lower cost.

With this new approach comes a new challenge in financing. Remediation and restoration technologies must be supported in new ways, as those solutions may not have a defined rate base. Increasing environmental stewardship through information, education, and the development of local watershed associations should help address this challenge. Promoting community support of less expensive technologies, with the understanding that everyone benefits from healthy embayments, should increase support for cost sharing.

The development of this 208 Plan Update has resulted in ways to share the cost with State and Federal partners, who also benefit from healthy Cape Cod embayments. The region has seen an expanded time frame for zero interest State Revolving Fund (SRF) loans, the potential for principal forgiveness on SRF loans through the Environmental Bond Bill, and Federal funding for innovative nitrogen reduction projects through the Southeast New England Program (SNEP).

Based on the balanced approach set forth in this Plan Update, Cape Cod can implement appropriate source reduction, remediation, and restoration strategies for between $2 and $3.8 billion to meet water quality goals. This savings has been demonstrated locally through the development of a 208 consistent process in the town of Orleans, which is estimating a 40% savings over their original comprehensive wastewater management plan by adopting the approach set forth in this plan.

Lowering the cost of projects by considering collection and treatment in areas where it's most appropriate, broadening the use of remediation and restoration technologies, and sharing the cost with our partners results in a lower cost for Cape Cod residents and affordable scenarios for improving water quality.

Glossary

Advanced Wastewater Treatment
Wastewater treatment process that includes combinations of physical (AWT) and chemical operation units designed to remove nutrients, toxic substances, or other pollutants. Advanced, or tertiary, treatment processes treat effluent from secondary treatment facilities using processes such as nutrient removal (nitrification, denitrification), filtration, or carbon adsorption. Tertiary treatment plants typically achieve about 95% removal of solids and BOD in addition to removal of nutrients or other materials.

Aerobic
A condition where free oxygen is present.

Algae
Any organisms of a group of chiefly aquatic microscopic nonvascular plants; most algae have chlorophyll as the primary pigment for carbon fixation. As primary producers, algae serve as the base of the aquatic food web, providing food for zooplankton and fish resources. An overabundance of algae in natural waters is known as eutrophication.

Algal bloom
Rapidly occurring growth and accumulation of algae within a body of water. It usually results from excessive nutrient loading and/or sluggish circulation regime with a long residence time. Persistent and frequent bloom can result in low oxygen conditions.

Anaerobic
A condition where free oxygen is not present or is unavailable.

Aquifer
Geologic formations (rock, sand, or gravel) that are saturated and sufficiently permeable to yield significant quantities of water.

Area of Critical Environmental Concern (ACEC)
An area that receives special recognition by the state of Massachusetts because of the quality, uniqueness, and significance of the area's natural and cultural resources. Designation creates a framework for local and regional stewardship of critical resources and ecosystems.

Attenuate
To reduce the force, amount, or magnitude.

Benthic Regeneration
The regrowth of organisms on lake or sea floors.

Best Management Practices (BMPs)
Conservation practices to reduce non-point and point pollution from sources such as construction, agriculture, timber harvesting, marinas, and stormwater.

Biochemical Oxygen Demand (BOD)
The amount of oxygen per unit volume of water required to bacterially or chemically oxidize (stabilize) the oxidizable matter in water. Biochemical oxygen demand measurements are usually conducted over specific time intervals (5,10,20,30 days). The term BOD5 generally refers to standard 5-day BOD test.

Build-Out
The total of new development and redevelopment that is projected to occur over a planning horizon, typically 20 years.

Checkerboard Sewer System
A wastewater collection system configured to serve only selected properties in a neighborhood. Such a system allows a town to restrict sewer service to only those lots in greatest need, and/or to preserve limited capacity for wastewater treatment or disposal.

Glossary

Chlorophyll
A group of green photosynthetic pigments that occur primarily in the chloroplast of plant cells. The amount of chlorophyll-a, a specific pigment, is frequently used as a measure of algal biomass in natural waters.

Cluster Wastewater Treatment System
As used in this document, a wastewater collection and treatment system that serves more than one property and has a wastewater flow less than 10,000 gallons per day.

Coliform Bacteria
A group of bacteria that normally live within the intestines of mammals, including humans. Coliform bacteria are used as an indicator of the presence of sewage in natural waters.

Combined Sewer Overflows (CSOs)
A combined sewer carries both wastewater and stormwater runoff. CSOs discharged to receiving water can result in contamination problems that may prevent the attainment of water quality standards.

Commercial Water Use
Water used for motels, hotels, restaurants, office buildings, and other commercial operations.

Concentration
Mass amount of a substance or material in a given unit volume of solution. Usually measured in milligrams per liter (mg/l) or parts per million (ppm).

Comprehensive Wastewater Management Plan (CWMP)
A plan that identifies all the community's wastewater needs and problems, evaluates alternative means of meeting those needs, selects the most cost-effective and environmentally appropriate remedy, and proposes an implementation plan and schedule.

Constructed Wetlands
A type of wastewater treatment that mimics a natural wetland ecosystem in which water-loving plants filter wastewater and debris through their roots.

Consumptive Use
That part of water withdrawn that is evaporated, transpired, or incorporated into a manufactured product, or consumed by humans or animals, or otherwise removed from the immediate waterbody environment.

Contamination
Act of polluting or making impure; any indication of chemical, sediment, or biological impurities.

Denitrification
A process of transforming nitrate to nitrite to nitrogen gas, often mediated by microbial processes.

Design Flow
The amount of sanitary sewage, in gallons per day, for which a system must be designed in accordance with CMR 15.203. Design-flow criteria are the amounts of sanitary sewage that are assumed to be generated by a specific land use. For example, under Title 5, one bedroom is assigned a design flow of 110 gallons per day.

Direct Discharge
An area where groundwater discharges directly to open coastal water.

Dissolved Oxygen (DO)
The amount of oxygen gas that is dissolved in water. It also refers to a measure of the amount of oxygen available for biochemical activity in water body, and as indicator of the quality of that water.

Glossary

Ecosystem
An interactive system that includes the organisms of a natural community association together with their abiotic physical, chemical, and geochemical environment.

Effluent
Sewage discharged into the environment, whether treated or not.

Embayment
A bay or a physical conformation resembling a bay.

Estuary
A partially enclosed body of water where fresh and salt water meet.

Eutrophication
A suite of changes in the condition of a water body that begins with excessive stimulation of growth of algae from nutrient inputs and leads to reduction in dissolved oxygen concentrations and sometimes to the death of organisms.

Floor Area Ratio (FAR)
A measure of building density calculated by dividing building square feet by lot area.

Flow Neutral Regulation
A sewer connection regulation that limits the amount of waste-water flow from a parcel to a pre-existing allowed flow.

Flushing Rate
The time it takes for an entire volume of water to be ex-changed, usually expressed in days or years.

Ground Water
Water below the land surface in a saturated zone.

Ground Water Discharge Permit Program
A Massachusetts regulation (314 CMR 5.00) that requires a permit for discharges of 10,000 gallons per day or more of pollutants to ground water.

Influent
Water volume flow rate or mass loading of a pollutant or other constituent into a water body or wastewater treatment plant.

Innovative/Alternative (I/A) Septic System
Any septic system or part of one that is not designed or constructed in a way consistent with a conventional Title 5 system. A conventional system has a septic tank, a distribution box or dosing mechanism, a soil-absorption system, and a reserve area. Some examples of alternative systems are recirculating sand filters, aerobic treatment units, peat filters, humus/composting toilets, and intermittent sand filters. Some I/A technologies are used to reduce nitrogen in nitrogen sensitive areas.

Interim Wellhead Protection Area (IWPA)
A public water system using wells or well fields that lack Massachusetts Department of Environmental Protection (DEP)-approved Zone IIs. The IWPA is a half-mile radius measured from the well or wellfield for sources with an approved pumping rate of 100,000 gallons per day or greater.

Loading, Load, Loading Rate
The total amount of material (pollutants) entering the system from one or multiple sources; measured as a rate in weight (mass) per unit time.

Glossary

Local Residence Time
The average time for water to migrate from a point in a sub-embayment to a point outside the sub-embayment.

Low Impact Development (LID)
An approach to land development (or redevelopment) that works with nature to manage stormwater as close to its source as possible. Includes principles such as preserving and recreating natural landscape features, minimizing effective imperviousness to create functional and appealing site drainage that treats stormwater as a resource rather than a waste product.

Massachusetts Estuaries Project (MEP)
A project of the Massachusetts Department of Environmental Protection (DEP) and the School for Marine Science and Technology at the University of Massachusetts, Dartmouth, that provides water quality, nutrient loading, and hydrodynamic information for 89 estuaries in southeastern Massachusetts. This information is combined in a linked watershed/estuary model that predicts the water quality changes that result from land use management decisions.

Massachusetts Groundwater Discharge Program
A state permit program to regulate effluent flows in excess of 10,000 gallons per day.

Milligrams Per Liter (mg/L)
A unit of measurement expressing the concentration of a constituent in solution as the weight (mass) of solute (1 milligram) per unit volume (1 liter) of water; equivalent to 1 part per million (ppm) for a water density. 1 g cm-3. 1 mg/L = 1000 ug/L; 1 g/L = 1000 mg/L.

Million Gallons Per Day (mgd)
Rate of water volume discharge representing a volume of 1 million gallons of water passing across a given location in a time interval of 1 day. A flow rate of 1 mgd = 1.54723 cubic feet per second (cfs) = 0.04381 cubic meters per second (cms).

National Pollutant Discharge Elimination System (NPDES)
A federal permit program under the Clean Water Act that regulates the discharge of pollutants into water bodies.

Natural Attenuation of Nitrogen
The naturally occurring retention or attenuation of nitrogen in wetlands or ponds.

Natural Resource Protection Zoning
A relatively new form of zoning that is a variation of a clustered subdivision, but with several enhancements. The number of allowed dwelling units is determined by a calculation that first eliminates the amount of important natural resource lands from the determination of the number of allowed units. The net acreage is then divided by the base density to determine the number of buildable units.

Nitrate
The nitrogen species in marine ecosystems that is most responsible for eutrophication, considered a broad indicator of contamination of ground water.

Nitrite
An intermediate oxidation state of nitrogen, between nitrate and ammonia.

Nitrogen
An element abundant in the atmosphere as dinitrogen gas. When combined with oxygen to form nitrate (NO3), it can cause excessive algal growth in marine waters, which can lead to eutrophication.

Nitrogen Loading
The input of nitrogen to estuaries and embayments from natural and human sources.

Nitrogen Removal Credit
Under Title 5, an innovative alternative septic systems that achieves an effluent nitrogen concentration of 19 milligrams per liter for a residential property and 25 milligrams per liter for a commercial property may qualify for a Nitrogen Removal Credit. The credit allows for an increase in design flow per acre in designated Nitrogen Sensitive Areas such as Zone IIs to public water supply wells, in other areas that have formally been designated as Nitrogen Sensitive Areas, and for new construction in areas that have both private wells and on-site septic systems.

Nitrogen Sensitive Area
A Massachusetts regulatory designation of an area as particularly sensitive to pollution from on-site wastewater systems and therefore requiring nitrogen-loading restrictions; includes Interim Wellhead Protection Areas and Zone IIs of public water supplies, areas with private wells, and Nitrogen Sensitive embayments or other areas that are designated as nitrogen sensitive under Title 5, based on appropriate scientific evidence.

Non-Conforming Use or Structure
A use or structure that no longer conforms to current zoning, but did conform when first built or established.

Non-Point Source of Pollution
Pollution from many diffuse sources that is carried to surface waters by runoff or ground water. Non-point source pollution is typically caused by sediment, nutrients, and organic and toxic substances originating from land use activities and/or the atmosphere. Any source of water pollution that does not meet the legal definition of a point source.

Nutrient Loading
The introduction of excessive amounts of nutrients, such as nitrogen or phosphorus, from wastewater or fertilizers, which ultimately reach ponds or estuaries.

Nutrient Management Regulations
Regulations that establish limits on the amount of flow from on-site septic systems serving new development and redevelopment or use changes.

Nutrients
Any substance required by plants and animals for normal growth and maintenance; for example, nitrogen and phosphorus.

On-Site Treatment and Disposal System
A natural system or mechanical device used to collect, treat, and discharge or reclaim wastewater from an individual dwelling without the use of community-wide sewers or a centralized treatment facility. It includes a septic tank and a leach field.

Organic Matter
The organic fraction that includes plant and animal residue at various stages of decomposition, cells and tissues of soil organisms, and substances synthesized by the soil population. Commonly determined as the amount of organic material contained in a soil or water sample.

Organic Nitrogen
Organic form of nitrogen bound to organic matter.

Outfall
Location point where wastewater or stormwater flows from a conduit, stream, or drainage ditch into natural waters.

Glossary

Outstanding Resource Waters
A Massachusetts Department of Environmental Protection (DEP) designation assigned to certain water bodies based on their outstanding socio-economic, recreational, ecological, and/or aesthetic values.

Oxygen Demand
Measure of the dissolved oxygen used by a system (microorganisms) and or chemical compounds in the oxidation of organic matter. See also biochemical oxygen demand.

Oxygen Depletion
Deficit of dissolved oxygen in a natural waters system due to oxidation of natural and anthropogenic organic matter.

Parts Per Million (PPM)
Measure of concentration of 1 part solute to 1 million parts water (by weight). See milligrams per liter.

Pathogen
An agent such as a virus, bacterium, or fungus capable of causing disease.

Permeable Reactive Barrier (PRB)
A carbon-containing reactive substance that promotes denitrification.

pH
A measure of acidity indicated by the logarithm of the reciprocal of the hydrogen ion concentration (activity) of a solution. pH values less than 7 are acidic; values greater than 7 are basic; pH of 7 is neutral. pH of natural waters typically ranges from 6-8.

Phosphorus
A nutrient essential for plant growth that can play a key role in stimulating the growth of aquatic plants in streams, rivers and lakes.

Phytoremediation
The use of plants to take up nutrients, contaminants, or other substances from soils, ground water, and surface water in order to restore ecosystem health.

Point Source of Pollution
As defined by the US Environmental Protection Agency (EPA), any discernible, confined, and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged.

Pollutant
A contaminant in a concentration or amount that adversely alters the physical, chemical, or biological properties of a natural environment. The term include pathogens, toxic metals, carcinogens, oxygen demanding substances, or other harmful substances.

Publicly Owned Treatment Works
Municipal wastewater treatment plant owned and operated by a (POTW) public governmental entity such as a town or city.

Public-Supply Withdrawals
Water withdrawn from surface water or groundwater by public or private water suppliers for use within a community. Water is used for domestic, commercial, industrial and public water uses such as fire fighting.

Recharge
The return of water to an underground aquifer by natural or artificial means.

Residence Time
The average time required for a particle of water or a pollutant to migrate through an estuary.

Salinity
The measure of the salt content of water. ,measured by weight as parts per thousand (ppt). Salinity concentrations range from 0.5-1 ppt for tidal fresh waters; 20-25 ppt for estuarine waters; 30 ppt for coastal waters to 35 ppt for the open ocean.

Secchi Depth
A measure of the light penetration into the water column. Light penetration is influenced by turbidity.

Septage
Material physically removed from any part of an on-site system, including, but not limited to, the solids, semi-solids, scum, sludge, and liquid contents of a septic tank, privy, chemical toilet, cesspool, holding tank, or other sewage waste receptacle. It does not include any material that is hazardous waste.

Septic Tank
A buried tank designed to receive and pre-treat wastewater from individual homes or facilities by separating settleable and floatable solids from wastewater. It is one component of an on-site wastewater treatment and disposal system.

Setbacks
A zoning term used to refer to the distance between a building and property lines.

Sewage
The water-carried human or animal wastes from residences, buildings, industrial establishments, or other places, together with such ground water infiltration and surface water as may be present. The liquid and solid waste carried off in sewers or drains.

Sewer
An artificial, usually underground, conduit for carrying off sewage or rainwater.

Sewerage
The removal of wastewater and refuse by means of sewers.

Sewershed
The properties within the area of service of a sewer system.

State Revolving Fund (SRF)
A Massachusetts program that helps with the financing of water pollution abatement projects. Two types of funding are provided through this program: the Clean Water and Drinking Water State Revolving Fund grants.

Station (Monitoring)
Specific location in a waterbody chosen to collect water samples for the measurement of water quality constituents. Stations are identified by an alphanumeric code identifying the agency source responsible for the collection of the data and a unique identifier code designating the location. Station measurements can be recorded from either discrete grab samples or continuous automated data acquisition systems. Station locations are typically sampled by state, federal or local agencies at periodic intervals (e.g., weekly, monthly, annual etc.) as part of a routine water quality monitoring program to track trends. Station locations can also be sampled only for a period of time needed to collect data for an intensive survey or a special monitoring program.

Stormwater Runoff
Rainfall and snow melt from diffuse (non-point) sources such as roofs, roadways, driveways, and other impervious surfaces.

Glossary

Sub-Embayment
A cove within an embayment.

Surface Waters
Water that is present above the substrate or soil surface. Usually refers to natural waterbodies such as streams, rivers, lakes and impoundments, and estuaries and coastal ocean.

System Residence Time
The average time for water to migrate through an entire estuarine system.

Tidal Flushing
The exchange of water from an estuarine system to the water body into which it empties.

Title 5
A Massachusetts state regulation (310 CMR 15.00) governing the siting, construction, inspection, upgrade, and expansion of on-site sewage treatment and disposal systems and the transport and disposal of septage.

Total Coliform Bacteria
A particular group of bacteria that are used as indicators of possible sewage pollution.

Total Maximum Daily Load (TMDL)
The greatest amount of a pollutant that a water body can accept and still meet water quality standards for protecting public health and maintaining the designated beneficial uses of those waters for drinking, swimming, recreation, and fishing.

Transfer of Development Rights (TDR)
A land use regulation that allows development rights to be transferred from an area where additional development is not desired, to an area where additional development is desired.

Wastewater Flow
The wastewater from septic systems that leaches into groundwater and flows through ground water into receiving waters such as a pond or estuary.

Waste Load Allocation (WLA)
The portion of a receiving water's total maximum daily load that is allocated to one of its existing or future point sources of pollution.

Wastewater Treatment
Chemical, biological, and mechanical processes applied to an industrial or municipal discharge or to any other sources of contaminated water in order to remove, reduce, or neutralize contaminants prior to discharge to a receiving water.

Water Pollution
Any condition of a waterbody that reflects unacceptable water quality or ecological conditions. Water pollution is usually the result of discharges of waste material from human activities into a waterbody.

Water Quality
Numerical description of the biological, chemical, and physical conditions of a water body. It is a measure of a water body to support beneficial uses.

Watershed
An area of land that drains to a common receiving body of water.

Zone I
The protective radius required around a public water supply well or wellfield.

Zone II or Zone of Contribution

The area of an aquifer that contributes water to a well under the most severe pumping and recharge conditions that can be realistically anticipated (180 days of pumping at approved yield, with no recharge from precipitation).

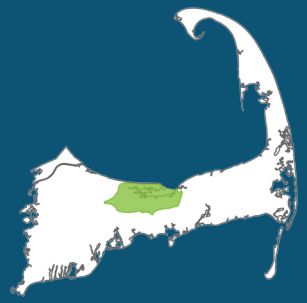
CCC Barnstable Harbor Watershed Report

WATERSHED REPORT: MID CAPE

Barnstable Harbor

BARNSTABLE, YARMOUTH & SANDWICH



WATER THREAT LEVEL

LOW

Barnstable Harbor Watershed

Introduction to the Watershed Reports

In 2001, the Massachusetts Estuaries Project (MEP) was established to evaluate the health of 89 coastal embayment ecosystems across southeastern Massachusetts. A collaboration between coastal communities, the Massachusetts Department of Environmental Protection (MassDEP), the School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth, the US Environmental Protection Agency (US EPA), the United States Geological Survey (USGS), the Massachusetts Executive Office of Energy and Environmental Affairs (EEA), and the Cape Cod Commission, the purpose of the MEP is to identify nitrogen thresholds and necessary nutrient reductions to support healthy ecosystems.

The Cape Cod 208 Plan Update, certified and approved by the Governor of the Commonwealth of Massachusetts and the US EPA in 2015, provides an opportunity and a path forward to implement responsible plans for the restoration of the waters that define Cape Cod.

On Cape Cod there are 53 embayment watersheds with physical characteristics that make them susceptible to nitrogen impacts. In its 2003 report, "The Massachusetts Estuaries Project – Embayment Restoration and Guidance for Implementation Strategies", MassDEP identifies the 46 Cape Cod embayments included in the

MEP. Thirty-three embayments studied to date require nitrogen reduction to achieve healthy ecosystem function. A Total Maximum Daily Load (TMDL) has been established (or a draft load has been identified and is under review) for these watersheds. For those embayments not studied, the 208 Plan Update recommends planning for a 25% reduction in nitrogen, as a placeholder, until information becomes available.

The 208 Plan Update directs Waste Treatment Management Agencies (WMAs) to develop watershed reports within 12 months of certification of the Plan Update. The Watershed Reports outline potential "bookend" scenarios for each watershed that include two scenarios to meet water quality goals in the watershed – a traditional scenario, which relies completely on the typical collection and centralized treatment of wastewater, and a non-traditional scenario, which uses remediation, restoration, and on-site reduction techniques to remove nutrients from raw and treated wastewater, groundwater and affected waterbodies.

The intent of the Watershed Reports is to outline two distinct approaches for addressing the nutrient problem. The reports are not intended to identify preferred and detailed plans for each watershed, but to facilitate discussions regarding effective and efficient solutions, particularly in watersheds shared by more than one town. In some cases, towns have provided information on collection areas and non-traditional technologies that have been specifically considered by that town.

The 208 Update developed a regionally consistent database of the nitrogen load entering each watershed. This data set includes estimates of wastewater, stormwater and fertilizer loads - similar to methodologies used by the MEP. Using this regionally consistent database, the Watershed MVP tool (wMVP) was developed so that different strategies (i.e., bookend scenarios) to reduce excess nitrogen load could be evaluated. The Watershed Reports use the MEP recommendations for the required nitrogen load reductions necessary to meet the threshold loads (that serve as the basis for nitrogen management), and then use the wMVP and the regionally consistent database values to develop bookend scenarios. There are variations of load between the MEP and wMVP, primarily due to differences in comparing older and newer databases.

Terms Defined

Total nitrogen load: the nitrogen load from the watershed contributed by septic, wastewater, fertilizer, stormwater, golf course, landfill, and natural sources.

Attenuated nitrogen load: the nitrogen load from the watershed that reaches the embayment after the effect of natural attenuation in wetlands, ponds or streams.

Threshold: the amount of nitrogen that a water body can receive from its watershed and still meet water quality goals; this number is based on MEP technical reports or Total Maximum Daily Load (TMDL) reports.

Reduction target: an approximation of the amount of nitrogen that needs to be removed from the watershed to achieve the threshold; this number is calculated by subtracting the threshold number from the attenuated total watershed load, and is for planning purposes only.

Percent contribution: the percent of attenuated nitrogen load that a town contributes to the watershed.

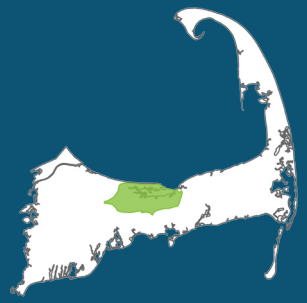
Kilogram responsibility: is calculated by applying the percent contribution to the reduction target and indicates the amount of nitrogen, in kg, that a community is responsible for addressing.

Total Maximum Daily Load: a regulatory term in the Clean Water Act, describing a value of the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards. Establishing a TMDL is necessary when a water body has been listed on the 303D list of impaired waters.

WATERSHED REPORT: MID CAPE

Barnstable Harbor

BARNSTABLE, YARMOUTH & SANDWICH



WATER THREAT LEVEL

LOW

The Barnstable Harbor estuary and embayment system is an estuary with its shoreline primarily located in the Town of Barnstable with a portion in Yarmouthport. Barnstable Harbor is a large embayment that receives tidal flow from Cape Cod Bay, with a 9-foot fluctuation, and extends nearly 5 miles towards the extensive Barnstable marsh. The bay supports a variety of recreational uses including boating, swimming, shell fishing and fin fishing.

The Problem

For the purposes of the Section 208 Plan Update, areas of wastewater need are primarily defined by the amount of nitrogen reduction required as defined by the Total Maximum Daily Load (TMDL) or Massachusetts Estuaries Project (MEP) technical report. An MEP report has not yet been completed for the Barnstable Harbor watershed. Due to its large tidal flow it is not expected to be severely overloaded with respect to nitrogen except for some of the upper reaches.

- **MEP TECHNICAL REPORT STATUS:** Data Collection Phase
- **TMDL STATUS:** In Progress

The Commission compiled the following updated water use and nitrogen loads using the regional wMVP database (see page 2), enabling a current estimate of nitrogen loading.

- **TOTAL WASTEWATER FLOW:** 291 MGY (million gal per year)
- **TOTAL UNATTENUATED NITROGEN LOAD:** 42,646 Kg/Y (kilograms per year)
- **ATTENUATED NITROGEN LOAD:** Not assessed

CONTRIBUTING TOWNS

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

- **BARNSTABLE:** 82%
- **YARMOUTH:** 14%
- **SANDWICH:** 4%

BARNSTABLE HARBOR ESTUARY

- **EMBAYMENT AREA:** 2,793 acres
- **EMBAYMENT VOLUME:** Unknown
- **2014 INTEGRATED LIST STATUS:** Category 5 for fecal coliform
  - Category 5: Waters requiring a TMDL
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

BARNSTABLE HARBOR WATERSHED

General watershed characteristics according to the current wMVP regional database (see figure on page 1 for watershed boundary) follow.

- **WATERSHED CHARACTERISTICS**
  - Acres: 17,043
  - Parcels: 5,542
  - % Developed Residential Parcels: 70%
  - Parcel Density: 3 acres per parcel

Freshwater Sources

PONDS

- **IDENTIFIED SURFACE WATERS:** 63
- **NUMBER OF NAMED FRESHWATER PONDS:** 18
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 8
- **2014 INTEGRATED LIST STATUS FOR NUTRIENTS:** None listed

Barnstable and Yarmouth have participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality.

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 3

  Scorton Creek, Sandwich
  - Average Flow: Not Assessed
  - Average Nitrate Concentrations: Not Assessed

  Bridge Creek, Barnstable
  - Average Flow: Not Assessed
  - Average Nitrate Concentrations: Not Assessed

  Brickyard Creek, Barnstable
  - Average Flow: Not Assessed
  - Average Nitrate Concentrations: Not Assessed

Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

DRINKING WATER SOURCES

- **WATER DISTRICTS:** 4
  - Barnstable Fire District
  - Centerville Osterville Marstons Mills Fire District
  - Hyannis Water Division
  - Yarmouth Water Division
- **GRAVEL PACKED WELLS:** 3
  - 1 has nitrate concentrations between 0.5 and 1 mg/L
  - 1 has nitrate concentrations between 1 and 2.5 mg/L
  - 1 has no nitrate concentration data
- **SMALL VOLUME WELLS:** 5
  - West Barnstable and East Sandwich are served exclusively by private wells.

Drinking water data from Cape Cod Commission and MassDEP data sources – nitrate values obtained from drinking water wells are from 2009-2012. The state and federal drinking water limit for nitrate is 10 mg/L. The Cape Cod Commission nitrate loading standard is 5 mg/l.

Degree of Impairment

Since there is no evidence of water quality impairment at this time, wastewater needs are determined based upon other factors, such as Title5 compliance.

Barnstable Harbor is listed as a Category 5 impaired water body for fecal coliform on the 2014 Integrated List of Impaired Waters.

This page intentionally left blank.

Traditional & Non-Traditional Scenarios

SCENARIO DEVELOPMENT

Through the 208 Stakeholder process, the Commission developed "bookend" scenarios – one looking at a possible solution using traditional collection and treatment, the other examining a possible suite of non-traditional technologies – to address the nitrogen management needs in each watershed. These bookend scenarios provide guidance for communities as they continue to discuss alternatives, priorities, and opportunities for identifying well-considered solutions that will address communities' needs and interests.

REGIONAL DATA

In preparation for this effort, the Commission collected regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used are 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water supplier and based on best available data. This approach allows for regionally consistent watershed scenario development.

WATERSHED SCENARIOS

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of residential load that would need to be collected if a traditional collection system and treatment facility was implemented. The pie charts show the load to be collected for treated effluent disposal both inside and outside the watershed.

Site specific analyses of collection areas may result in the need to collect wastewater from more or fewer parcels to meet the nitrogen reduction target. The scenarios presented are conceptual and are meant to inform discussions regarding effective and efficient solutions; they are not specific recommendations and should be viewed as resource information for additional and more detailed wastewater management planning.

TOTAL UNATTENUATED NITROGEN LOAD VALUES (FROM WMVP)

Barnstable Harbor Nitrogen Sources	Total Unattenuated Watershed Nitrogen Load (kg-N/yr)
Wastewater[1]	28,965
Fertilizer[2]	4,717
Stormwater	5,521
Other[3]	3,443
TOTAL WATERSHED LOAD	42,646
Total Watershed Threshold[4]	31,985
TOTAL UNATTENUATED LOAD TO BE REMOVED	10,662

1. Includes nitrogen loads from septic systems and wastewater treatment facilities.
2. Includes nitrogen loads from lawns, cranberry bogs, and golf courses.
3. Includes nitrogen loads from landfills and atmospheric deposition to vacant land.
4. Assumes 25% reduction is needed, as no MEP report has been completed for this watershed and no threshold has been established.

Traditional & Non-Traditional Scenarios

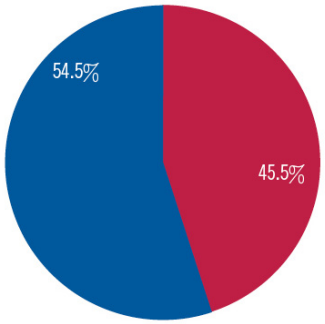
Non-Traditional

UNIT OF APPLIED TECHNOLOGY	ATTENUATED NITROGEN REMOVED IN KG/Y
25 % Nitrogen Reduction - Fertilizer Management	1,179
25 % Nitrogen Reduction - Stormwater Mitigation	1,380
2 Acres - Constructed Wetlands (Collection System)	1,000
5,600 Linear Feet - Permeable Reactive Barrier (PRB) (Capture load calculated by wMVP: 528.3 kg/Y)	383
150 Acres - Fertigation - Turf	600
29 Acres - Aquaculture/Oyster Beds	7,125
TOTAL	**10,668**

A summary of the approach and methodology that was applied using non-traditional technologies follows at the end of this report.

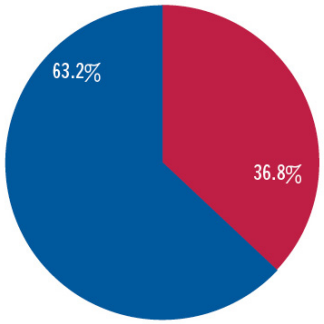
Traditional

CENTRALIZED TREATMENT WITH DISPOSAL INSIDE THE WATERSHED

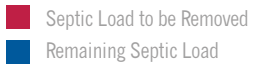


Assumes load to be collected and treated is disposed in the watershed, requiring additional collection to offset the load.

CENTRALIZED TREATMENT WITH DISPOSAL OUTSIDE THE WATERSHED



Assumes that the load to be collected and treated is removed from the watershed so no offset is required.



Town of Yarmouth Local Progress

In 2010, the Town of Yarmouth submitted its Comprehensive Wastewater Management Plan (CWMP) as a Draft Environmental Impact Report (DEIR). The draft CWMP targeted areas that would require wastewater collection to restore water quality in the Lewis Bay and Parkers River watersheds and deal with the Title 5 constraints on economic redevelopment in the area of Route 28. The town's plan included approximately 125 miles of sewer lines and the collection of 2.75 million gallons per day (MGD) of wastewater to be treated at a single facility in the Parkers River watershed. The project would ultimately serve 9,580 properties by 2035. Phase 1 of the plan would begin with the treatment facility and main trunk line sewer to serve Route 28 and portions of the Parkers River and Lewis Bay watershed.

The plan relies on gravity, pressure, and vacuum sewers. The MEP nitrogen reduction goals were the primary factor in choosing sewering locations. The phasing of these sewered areas also takes the town's economic goals into consideration.

The town submitted its Final Environmental Impact Report (FEIR) and received Massachusetts Environmental Policy Act (MEPA) approval in July 2011, but did not complete the Cape Cod Commission Development of Regional Impact (DRI) process before going to September 2011 Town Meeting to seek Phase 1 design and construction funds. Phases 1 through 5 were scheduled to be implemented over a 25-year period. The estimated cost of the total plan was $275 million. The first phase had an estimated cost of $55 million. Town Meeting did not approve the expenditure. The town withdrew the CWMP from the DRI review process.

Wastewater planning in the community had effectively come to a stop prior to the development of the 208 Plan Update.

In January 2016 town staff met with the Board of Selectmen to discuss a new financing plan for implementation of a program that would meet water quality standards in all of their watersheds.

The recommended plan includes a combination of traditional sewering methods with centralized treatment facilities as well as non-traditional nitrogen management options including a permeable reactive barrier (PRB) at the Buck Island Road effluent recharge site. The Town of Yarmouth is proposing a phased wastewater program that includes a collection system, a conveyance system and a centralized treatment facility, each constructed over several years. In addition to the proposed sewering, the recommended plan involves public outreach to promote nitrogen reduction and to prevent sewer system inflow, zoning modifications for growth management and establishment of the activity centers, development of sewer ordinances, and continued maintenance of Title 5 and I/A systems in the northern and western areas of the town that will not be served by the proposed wastewater collection system. The town also plans to implement stormwater and fertilizer improvement programs. As suggested in the 208 Plan Update, up to a 25% nitrogen reduction credit can be obtained by towns that implement stormwater and fertilizer management programs to reduce nitrogen contributions to each watershed.

During the spring 2016 town meeting, the town approved $200,000 for additional CWMP planning.

In April 2016, Yarmouth submitted a request for assistance to continue CWMP development and town staff met with the Commission to discuss the request in early May.

In June 2016, Yarmouth received $35,000 from the Commission for the Towns of Dennis, Harwich and Yarmouth for a regional treatment facility cost study. Funding was part of $142,149 in local grants made by the Commission in support of 208 Plan implementation.

At the Spring 2017 Town Meeting appropriated $200,000 for wastewater planning and engineering services including engineering studies and evaluation of recharge sites; updating, modification, and pre-implementation services for the Comprehensive Wastewater Management Plan and support for related filings with the Massachusetts Environmental Policy Act office and the Cape Cod Commission.

Town of Sandwich Local Progress

The Town of Sandwich has an established water quality committee to oversee water quality and wastewater planning efforts. In October 2015 town staff and their consultant (Wright-Pierce) met with Cape Cod Commission staff to discuss watershed planning, decision support tools, and scenario development for Sandwich watersheds. In the same month the town was approached by Mashpee regarding approaches for Popponesset Bay, and a potential watershed permit, and has agreed to participate with Mashpee and Barnstable in this shared effort. It is expected that Barnstable, Mashpee, and Sandwich will collaborate on the first watershed permit in the region in close coordination with the Cape Cod Commission and the Massachusetts Department of Environmental Protection.

Previously the committee developed a scope of work for a Comprehensive Wastewater Management Plan (CWMP) and submitted the scope under the Sagamore Lens Natural Resource Damages Assessment, related to past groundwater contamination at the Textron facility at Joint Base Cape Cod (JBCC). The town received an award of $400,000 t0 conduct its water/wastewater plan and completed a comprehensive needs assessment, as well as an interim wastewater solutions plan to accommodate economic development in the South Sandwich Village Center.

The town spent several years working with a private developer on a development project that included a public-private wastewater component for the construction of a facility that would accommodate the private project, in addition to some public wastewater needs. That project will not be completed, but the town is again seeking a private partner to create new economic growth and to potentially participate in infrastructure development.

The town has participated in discussions at JBCC about the potential use of its existing wastewater infrastructure as a regional option for the Upper Cape towns.

In February 2016 the Town of Sandwich requested a meeting with Commission staff to discuss watershed scenarios and potential modifications to watersheds in which Sandwich has jurisdiction. The town provided collection footprints and assumptions for a single treatment facility to serve all three watersheds (Popponesset Bay, Three Bays, and Waquoit Bay), consistent with the Sandwich CWMP, and identified locations for non-traditional approaches, in addition to credits for stormwater and fertilizer reduction. The Town proposes a 25% fertilizer management credit and a 6.25% stormwater management credit. While the proposed interventions, alone, do not meet the nitrogen allocations identified in Appendix 8C of the 208 Plan Update, the town has expressed a preference to rely on nutrient trading or cost sharing to reduce the load allocated to the downgradient towns in the shared watersheds of Popponesset Bay, Three Bays and Waquoit Bay, where nitrogen reductions can be more cost effectively attained.

Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion.

Barnstable is also working closely with Mashpee and Sandwich on a watershed permit for the Popponesset Bay watershed.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Methodology for Selecting Non-Traditional Technology Scenarios

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology were derived from the Technologies Matrix. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology are noted below, based on the Technologies Matrix or newer data. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

Regional credits were developed for potential stormwater retrofits and fertilizer reductions. They were calculated as a percent reduction of existing nitrogen loads as identified in the MEP reports and updated GIS data developed by the Cape Cod Commission.

- **STORMWATER MANAGEMENT:** Most Cape communities have already begun the process of identifying significant untreated stormwater discharges and developing appropriate mitigation projects. With the prospect of the MS4 regulatory requirements it was assumed that additional mitigation efforts would be implemented. Based upon the evidence developed by the University of New Hampshire Stormwater Center that several vegetated stormwater management practices (including bioretention and constructed wetlands) are able to achieve nitrogen reductions of 50% or more and the assumption that only a portion (estimated at 50%) of identified sites would be retrofitted a 25% nitrogen reduction credit was assumed for each watershed. Specific locations and number of locations were not identified; this was deferred to individual towns to consider as part of the suite of nitrogen management strategies.
- **FERTILIZER REDUCTIONS:** Based upon the success of most Cape Cod towns to implement either regulatory or non-regulatory fertilizer management programs and the efforts of the Cape Cod Extension Service in educating homeowners a 25% reduction in fertilizer applications was assumed for each watershed.

Regional GIS screening methods were developed to identify locations for some non-traditional technologies. A GIS viewer was developed as an on-line tool for staff and consultants to utilize during the watershed planning process.

- **CONSTRUCTED WETLANDS/ PHYTOREMEDIATION:** A GIS-based screening method was developed by the Cape Cod Commission to identify and rank parcels of land that have potential for the location of constructed wetlands and phytoremediation. The ranking utilized parcel size and ownership, depth to groundwater, suitable soils, distance from wetlands, and undeveloped parcels. A nitrogen removal rate of 500 kg/Y/acre and 532 kg/Y/acre was used for Constructed Wetlands and Phytoremediation, respectively.
- **PERMEABLE REACTIVE BARRIERS (PRBS):** A GIS-based screening method was developed to identify existing roads that are proximate to receiving waters, downgradient of high density development, run perpendicular to groundwater flow (to have the highest potential to intercept nutrients in groundwater), and where the depth to groundwater is relatively shallow to maximize the area of saturated thickness treated in the aquifer.

Methodology for Selecting Non-Traditional Technology Scenarios

- **FERTIGATION WELLS:** Golf courses were mapped to identify areas where fertigation wells could be utilized to recapture nitrogen-enriched groundwater and re-apply it to the managed turf areas to serve both irrigation and fertilization needs. Most golf courses were assumed to be eighteen holes with a fertilized area of 75 acres. Fertigation water was assumed to have an average concentration of 5 mg/liter. An uptake/attenuation rate of 80% was applied resulting in an assumed nitrogen reduction of 300 kg/year for each golf course with effectively located fertigation wells. In some cases other irrigated areas (such as athletic fields and cemeteries) were identified as potential fertigation locations. Assuming the use of 730 gpd/acre for turf areas, a nitrogen removal rate of 4 kg/y/acre was used for fertigation of turf areas. Assuming a higher flow rate of 2,200 gpd/acre for cranberry bogs, a 12 kg/y/acre removal rate was used for fertigation of cranberry bogs.

The MVP tool and other site-specific tools were utilized to quantify nitrogen load reductions for several potential NT interventions.

- **PERMEABLE REACTIVE BARRIERS:** for each PRB that was identified during the prior GIS-screening process an approximate capture area was identified using available water table maps and the wMVP tool. Upgradient contributing areas were digitized within wMVP and the nitrogen load was calculated. A nitrogen reduction of 72.5% was applied (calculated as an average of the reported attenuation range from the Technologies Matrix).
- **CONSTRUCTED WETLANDS (WITH COLLECTION):** Constructed wetlands were considered as a tertiary, polishing treatment for existing wastewater treatment plants. This included small-scale wastewater treatment systems. A nitrogen removal rate of 500 kg/Y/acre was used.
- **AQUACULTURE/OYSTER REEFS:** Potential areas for aquaculture and/or oyster reef restoration were considered based upon discussions with town representatives and review of maps to identify potential areas for these operations without significant conflicts to navigation. In some cases actual recent aquaculture expansions were included where they were developed after the MEP reports were prepared. An assumption of 1 million oysters per acre was used with a nitrogen removal rate of 250 kg/Y/acre.
- **FLOATING CONSTRUCTED WETLANDS:** Potential areas for floating wetlands were considered in areas where no conflicts with navigation or swimming areas were identified. A nitrogen removal rate of 0.4 kg/Y/sq foot was used.
- **INLET WIDENING AND COASTAL HABITAT RESTORATION:** Only considered in areas where these projects were identified by towns or state agencies and where detailed hydrologic investigations and modeling had been performed due to wide variations in nitrate load reduction, flushing impacts, impacts on flooding, and costs (dredging only, replacing infrastructure, removing and replacing roadways or bridges, etc.). Nitrogen removal rates were based on MEP or other studies.
- **INNOVATIVE & ALTERNATIVE SEPTIC SYSTEMS AND ECOTOILETS:** In most cases specific locations for these technologies were not identified. Rather general estimates for the percent adoption were provided based upon discussions with the stakeholder groups and their views on potential adoption rates. In some watersheds a 5% adoption rate was included based upon this stakeholder input. In a limited number of instances specific locations for these technologies were included based upon town input and suggestions. A nitrogen removal rate of 1.658 kg/Y for each system was used for I&A Septic Systems, and 2.984 kg/Y for enhanced I&A systems. A removal rate of 2.542 kg/Y was used for each home installation of an Ecotoilet, and 0.467 kg/Y for installation of urine diversion toilets in public settings.

Finally, the locations of specific technologies were discussed during the 208 stakeholder engagement process. Stakeholders across the Cape 'groundtruthed' potential NT locations and NT scenarios were adjusted accordingly.

Centerville River Watershed

Introduction to the Watershed Reports

In 2001, the Massachusetts Estuaries Project (MEP) was established to evaluate the health of 89 coastal embayment ecosystems across southeastern Massachusetts. A collaboration between coastal communities, the Massachusetts Department of Environmental Protection (MassDEP), the School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth, the US Environmental Protection Agency (US EPA), the United States Geological Survey (USGS), the Massachusetts Executive Office of Energy and Environmental Affairs (EEA), and the Cape Cod Commission, the purpose of the MEP is to identify nitrogen thresholds and necessary nutrient reductions to support healthy ecosystems.

The Cape Cod 208 Plan Update, certified and approved by the Governor of the Commonwealth of Massachusetts and the US EPA in 2015, provides an opportunity and a path forward to implement responsible plans for the restoration of the waters that define Cape Cod.

On Cape Cod there are 53 embayment watersheds with physical characteristics that make them susceptible to nitrogen impacts. In its 2003 report, "The Massachusetts Estuaries Project – Embayment Restoration and Guidance for Implementation Strategies", MassDEP identifies the 46 Cape Cod embayments included in the

MEP. Thirty-three embayments studied to date require nitrogen reduction to achieve healthy ecosystem function. A Total Maximum Daily Load (TMDL) has been established (or a draft load has been identified and is under review) for these watersheds. For those embayments not studied, the 208 Plan Update recommends planning for a 25% reduction in nitrogen, as a placeholder, until information becomes available.

The 208 Plan Update directs Waste Treatment Management Agencies (WMAs) to develop watershed reports within 12 months of certification of the Plan Update. The Watershed Reports outline potential "bookend" scenarios for each watershed that include two scenarios to meet water quality goals in the watershed – a traditional scenario, which relies completely on the typical collection and centralized treatment of wastewater, and a non-traditional scenario, which uses remediation, restoration, and on-site reduction techniques to remove nutrients from raw and treated wastewater, groundwater and affected waterbodies.

The intent of the Watershed Reports is to outline two distinct approaches for addressing the nutrient problem. The reports are not intended to identify preferred and detailed plans for each watershed, but to facilitate discussions regarding effective and efficient solutions, particularly in watersheds shared by more than one town. In some cases, towns have provided information on collection areas and non-traditional technologies that have been specifically considered by that town.

The 208 Update developed a regionally consistent database of the nitrogen load entering each watershed. This data set includes estimates of wastewater, stormwater and fertilizer loads - similar to methodologies used by the MEP. Using this regionally consistent database, the Watershed MVP tool (wMVP) was developed so that different strategies (i.e., bookend scenarios) to reduce excess nitrogen load could be evaluated. The Watershed Reports use the MEP recommendations for the required nitrogen load reductions necessary to meet the threshold loads (that serve as the basis for nitrogen management), and then use the wMVP and the regionally consistent database values to develop bookend scenarios. There are variations of load between the MEP and wMVP, primarily due to differences in comparing older and newer databases.

Terms Defined

Total nitrogen load: the nitrogen load from the watershed contributed by septic, wastewater, fertilizer, stormwater, golf course, landfill, and natural sources.

Attenuated nitrogen load: the nitrogen load from the watershed that reaches the embayment after the effect of natural attenuation in wetlands, ponds or streams.

Threshold: the amount of nitrogen that a water body can receive from its watershed and still meet water quality goals; this number is based on MEP technical reports or Total Maximum Daily Load (TMDL) reports.

Reduction target: an approximation of the amount of nitrogen that needs to be removed from the watershed to achieve the threshold; this number is calculated by subtracting the threshold number from the attenuated total watershed load, and is for planning purposes only.

Percent contribution: the percent of attenuated nitrogen load that a town contributes to the watershed.

Kilogram responsibility: is calculated by applying the percent contribution to the reduction target and indicates the amount of nitrogen, in kg, that a community is responsible for addressing.

Total Maximum Daily Load: a regulatory term in the Clean Water Act, describing a value of the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards. Establishing a TMDL is necessary when a water body has been listed on the 303D list of impaired waters.

Centerville River

BARNSTABLE

WATER THREAT LEVEL
MODERATE

The Centerville River estuary and embayment system is located wholly within the Town of Barnstable. It is comprised of a number of sub-basins, such as East Bay and Scudder Bay/Bumps River and supports a variety of recreational uses including boating, swimming, shell fishing and fin fishing.

The Problem

The Massachusetts Estuaries Project (MEP) technical report (available at http://www.mass.gov/eea/agencies/massdep/water/watersheds/the-massachusetts-estuaries-project-and-reports.html) indicates that the Centerville River system exceeds its critical threshold for nitrogen, resulting in impaired water quality. A MEP technical report has been completed and a Total Maximum Daily Load (TMDL) for nitrogen has been developed and approved.

- **MEP TECHNICAL REPORT STATUS:** Final
- **TMDL STATUS:** Final TMDL

Watershed nitrogen load characteristics were published in the 2006 MEP report for Centerville River, reflecting current conditions at the time of writing:

- **TOTAL ATTENUATED NITROGEN LOAD:** 48,245 Kg/Y (MEP Chapter VIII)
- **SOURCES OF ATTENUATED WATERSHED NITROGEN LOAD:**
  - 87% Septic Systems
  - 6% Fertilizer
  - 7% Stormwater From Impervious Surfaces

Since the MEP report, the Commission compiled the following updated water use and nitrogen loads using the regional wMVP database, enabling a more current estimate of nitrogen loading (see figure on page 1 for watershed boundary delineation):

- **TOTAL WASTEWATER FLOW:** 427 MGY (million gal per year)
  - Treated Wastewater Flow: 4 MGY
  - Septic Flow: 423 MGY
- **TOTAL ATTENUATED NITROGEN LOAD (WMVP):** 44,573 Kg/Y

CONTRIBUTING TOWNS

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

- **BARNSTABLE:** 100%

THE MEP RESTORATION SCENARIO:

- **WATERSHED TOTAL NITROGEN REDUCTION TARGET:** 28%
- **WATERSHED SEPTIC REDUCTION TARGET:** 34% (The scenario represents the aggregated sub-embayment percent removal targets from the MEP technical report)

CENTERVILLE RIVER ESTUARY

- **EMBAYMENT AREA:** 218 acres
- **EMBAYMENT VOLUME:** 39.8 million cubic feet
- **2014 INTEGRATED LIST STATUS:** Category 4a
  - Bumps River: fecal coliform
  - Centerville River: fecal coliform, estuarine bioassessments and nitrogen
  - Category 4a, TMDL is completed
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

CENTERVILLE RIVER WATERSHED

General watershed characteristics according to the current wMVP regional database (see figure on page 1 for watershed boundary) follow.

- **WATERSHED CHARACTERISTICS**
  - Acres: 6,739
  - Parcels: 7,491
  - % Developed Residential Parcels: 88%
  - Parcel Density: 0.9 acres per parcel

Freshwater Sources

PONDS

- **IDENTIFIED SURFACE WATERS:** 39
- **NUMBER OF NAMED FRESHWATER PONDS:** 14
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 8
- **2014 INTEGRATED LIST STATUS:** 6 ponds listed in Category 5 requiring a TMDL.

Three ponds within the adjacent Three Bays watershed (Shubael Pond, Micahs Pond and Joshuas Pond) also contribute to Centerville River. The recent comprehensive wastewater management plan (CWMP) included the preparation of a Pond Action Report.

Yarmouth has participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality.

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 4

Skunknett River:
- Average Flow: 13,925 cubic meters per day (m3/d)
- Average Nitrate Concentrations: 1.113 milligrams per liter (mg/L)

Bumps River:
- Average Flow: 5,679 m3/d
- Average Nitrate Concentrations: 2.207 mg/L

Long Pond Stream:
- Average Flow: 6,518 m3/d
- Average Nitrate Concentrations: 0.199 mg/L

Lake Elizabeth:
- Average Flow: 1,547 m3/d
- Average Nitrate Concentrations: 0.937 mg/L

Stream data from MEP technical report. Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

DRINKING WATER SOURCES

- **WATER DISTRICTS:** 2
  - Hyannis Water District
  - Centerville-Osterville-Marstons Mills (COMM) Water District
- **GRAVEL PACKED WELLS:** 6
  - 1 has nitrate concentrations between 1 and 2.5 mg/L
  - 5 have nitrate concentrations between 2.5 and 5 mg/L
- **SMALL VOLUME WELLS:** 0

Drinking water data from Cape Cod Commission and MassDEP data sources – nitrate values obtained from drinking water wells are from 2009-2012. The state and federal drinking water limit for nitrate is 10 mg/L. The Cape Cod Commission nitrate loading standard is 5 mg/l.

Degree of Impairment and Areas of Need

For the purposes of the 208 Plan Update, areas of need are primarily defined by the amount of nitrogen reduction required as defined by the TMDL and/or MEP technical report. For the Centerville River, this amount is 34% of the septic load or 28% of the total attenuated nitrogen load. The MEP technical report also provides a specific targeted amount of nitrogen reduction required by subwatershed, (see the figures: Subwatersheds with Total and Septic Attenuated Nitrogen Removal Targets).

The nitrogen load from the watershed exceeds the threshold for the Centerville River, resulting in impaired water quality. Lower portions of Centerville River have generally good water quality supported by tidal flushing and significant attenuation to contributing areas, while the upper reach of Centerville

River, Centerville River East, has decreased water quality. The ecological health of a water body is determined from water quality, extent of eelgrass, assortment of benthic fauna, and dissolved oxygen and ranges from severe degradation, significantly impaired, moderately impaired, or healthy habitat conditions.

ECOLOGICAL CHARACTERISTICS AND WATER QUALITY

The MEP report provides the following characterization of the estuary's health:

- **OVERALL ECOLOGIC CONDITION:** Healthy to Significantly Impaired
- **UPPER CENTERVILLE RIVER:** Healthy

Traditional & Non-Traditional Scenarios

SCENARIO DEVELOPMENT

Through the 208 Stakeholder process, the Commission developed "bookend" scenarios – one looking at a possible solution using traditional collection and treatment, the other examining a possible suite of non-traditional technologies – to address the nitrogen management needs in each watershed. These bookend scenarios provide guidance for communities as they continue to discuss alternatives, priorities, and opportunities for identifying well-considered solutions that will address communities' needs and interests.

REGIONAL DATA

In preparation for this effort, the Commission collected regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used are 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water supplier and based on best available data. This approach allows for regionally consistent watershed scenario development.

WATERSHED SCENARIOS

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of residential load that would need to be collected if a traditional collection system and treatment facility was implemented. The pie charts show the load to be collected for treated effluent disposal both inside and outside the watershed.

Site specific analyses of collection areas may result in the need to collect wastewater from more or fewer parcels to meet the nitrogen reduction target. The scenarios presented are conceptual and are meant to inform discussions regarding effective and efficient solutions; they are not specific recommendations and should be viewed as resource information for additional and more detailed wastewater management planning.

In Centerville River, the Town of Barnstable has done additional and more detailed planning. Included in the last section of this report is a description of their efforts, along with details of plans developed to date.

TOTAL ATTENUATED WATERSHED NITROGEN LOAD VALUES (FROM WMVP)

Centerville River Nitrogen Sources	Total Attenuated Watershed Nitrogen Load (kg-N/yr)
Wastewater[1]	36,000
Fertilizer[2]	3,166
Stormwater	4,475
Other[3]	932
TOTAL WATERSHED LOAD	44,573
Total Watershed Threshold	34,833
TOTAL ATTENUATED LOAD TO BE REMOVED	9,740

1. Includes nitrogen loads from septic systems and wastewater treatment facilities.
2. Includes nitrogen loads from lawns, cranberry bogs, and golf courses.
3. Includes nitrogen loads from landfills and atmospheric deposition to vacant land.

Traditional & Non-Traditional Scenarios

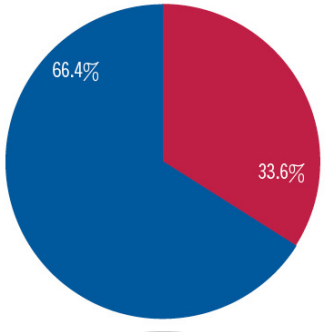
Non-Traditional

UNIT OF APPLIED TECHNOLOGY	ATTENUATED NITROGEN REMOVED IN KG/Y
25 % Nitrogen Reduction - Fertilizer Management	792
25 % Nitrogen Reduction - Stormwater Mitigation	1,119
6 Acres - Constructed Wetlands (Collection System)	3,000
5,600 Linear Feet - Permeable Reactive Barrier (PRB) (Capture load calculated by wMVP: 6,863.4 kg/Y)	4,976
150 Acres - Fertigation - Turf	600
9 Acres - Aquaculture/Oyster Beds	2,200
1,285 People Per Year - UD School or Public Facility	600
TOTAL	**13,287**

A summary of the approach and methodology that was applied using non-traditional technologies follows at the end of this report.

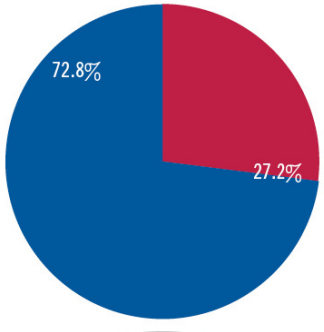
Traditional

CENTRALIZED TREATMENT WITH DISPOSAL INSIDE THE WATERSHED

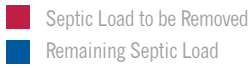


Assumes load to be collected and treated is disposed in the watershed, requiring additional collection to offset the load.

CENTRALIZED TREATMENT WITH DISPOSAL OUTSIDE THE WATERSHED



Assumes that the load to be collected and treated is removed from the watershed so no offset is required.



Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion. Those scenarios are included in this report.

Barnstable is also working closely with Mashpee and Sandwich on a watershed permit for the Popponesset Bay watershed.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Methodology for Selecting Non-Traditional Technology Scenarios

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology were derived from the Technologies Matrix. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology are noted below, based on the Technologies Matrix or newer data. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

Regional credits were developed for potential stormwater retrofits and fertilizer reductions. They were calculated as a percent reduction of existing nitrogen loads as identified in the MEP reports and updated GIS data developed by the Cape Cod Commission.

- **STORMWATER MANAGEMENT:** Most Cape communities have already begun the process of identifying significant untreated stormwater discharges and developing appropriate mitigation projects. With the prospect of the MS4 regulatory requirements it was assumed that additional mitigation efforts would be implemented. Based upon the evidence developed by the University of New Hampshire Stormwater Center that several vegetated stormwater management practices (including bioretention and constructed wetlands) are able to achieve nitrogen reductions of 50% or more and the assumption that only a portion (estimated at 50%) of identified sites would be retrofitted a 25% nitrogen reduction credit was assumed for each watershed. Specific locations and number of locations were not identified; this was deferred to individual towns to consider as part of the suite of nitrogen management strategies.
- **FERTILIZER REDUCTIONS:** Based upon the success of most Cape Cod towns to implement either regulatory or non-regulatory fertilizer management programs and the efforts of the Cape Cod Extension Service in educating homeowners a 25% reduction in fertilizer applications was assumed for each watershed.

Regional GIS screening methods were developed to identify locations for some non-traditional technologies. A GIS viewer was developed as an on-line tool for staff and consultants to utilize during the watershed planning process.

- **CONSTRUCTED WETLANDS/ PHYTOREMEDIATION:** A GIS-based screening method was developed by the Cape Cod Commission to identify and rank parcels of land that have potential for the location of constructed wetlands and phytoremediation. The ranking utilized parcel size and ownership, depth to groundwater, suitable soils, distance from wetlands, and undeveloped parcels. A nitrogen removal rate of 500 kg/Y/acre and 532 kg/Y/acre was used for Constructed Wetlands and Phytoremediation, respectively.
- **PERMEABLE REACTIVE BARRIERS (PRBS):** A GIS-based screening method was developed to identify existing roads that are proximate to receiving waters, downgradient of high density development, run perpendicular to groundwater flow (to have the highest potential to intercept nutrients in groundwater), and where the depth to groundwater is relatively shallow to maximize the area of saturated thickness treated in the aquifer.

Methodology for Selecting Non-Traditional Technology Scenarios

- **FERTIGATION WELLS:** Golf courses were mapped to identify areas where fertigation wells could be utilized to recapture nitrogen-enriched groundwater and re-apply it to the managed turf areas to serve both irrigation and fertilization needs. Most golf courses were assumed to be eighteen holes with a fertilized area of 75 acres. Fertigation water was assumed to have an average concentration of 5 mg/liter. An uptake/attenuation rate of 80% was applied resulting in an assumed nitrogen reduction of 300 kg/year for each golf course with effectively located fertigation wells. In some cases other irrigated areas (such as athletic fields and cemeteries) were identified as potential fertigation locations. A nitrogen removal rate of 4 kg/Y/acre was used.

The MVP tool and other site-specific tools were utilized to quantify nitrogen load reductions for several potential NT interventions.

- **PERMEABLE REACTIVE BARRIERS:** for each PRB that was identified during the prior GIS-screening process an approximate capture area was identified using available water table maps and the wMVP tool. Upgradient contributing areas were digitized within wMVP and the nitrogen load was calculated. A nitrogen reduction of 72.5% was applied (calculated as an average of the reported attenuation range from the Technologies Matrix).
- **CONSTRUCTED WETLANDS (WITH COLLECTION):** Constructed wetlands were considered as a tertiary, polishing treatment for existing wastewater treatment plants. This included small-scale wastewater treatment systems. A nitrogen removal rate of 500 kg/Y/acre was used.
- **AQUACULTURE/OYSTER REEFS:** Potential areas for aquaculture and/or oyster reef restoration were considered based upon discussions with town representatives and review of maps to identify potential areas for these operations without significant conflicts to navigation. In some cases actual recent aquaculture expansions were included where they were developed after the MEP reports were prepared. An assumption of 1 million oysters per acre was used with a nitrogen removal rate of 250 kg/Y/acres.
- **FLOATING CONSTRUCTED WETLANDS:** Potential areas for floating wetlands were considered in areas where no conflicts with navigation or swimming areas were identified. A nitrogen removal rate of 0.4 kg/Y/sq foot was used.
- **INLET WIDENING AND COASTAL HABITAT RESTORATION:** Only considered in areas where these projects were identified by towns or state agencies and where detailed hydrologic investigations and modeling had been performed due to wide variations in nitrate load reduction, flushing impacts, impacts on flooding, and costs (dredging only, replacing infrastructure, removing and replacing roadways or bridges, etc.). Nitrogen removal rates were based on MEP or other studies.
- **INNOVATIVE & ALTERNATIVE SEPTIC SYSTEMS AND ECOTOILETS:** In most cases specific locations for these technologies were not identified. Rather general estimates for the percent adoption were provided based upon discussions with the stakeholder groups and their views on potential adoption rates. In some watersheds a 5% adoption rate was included based upon this stakeholder input. In a limited number of instances specific locations for these technologies were included based upon town input and suggestions. A nitrogen removal rate of 1.658 kg/Y for each system was used for I&A Septic Systems, and 2.984 kg/Y for enhanced I&A systems. A removal rate of 2.542 kg/Y was used for each home installation of an Ecotoilet, and 0.467 kg/Y for installation of urine diversion toilets in public settings.

Finally, the locations of specific technologies were discussed during the 208 stakeholder engagement process. Stakeholders across the Cape 'groundtruthed' potential NT locations and NT scenarios were adjusted accordingly.

CCC Lewis Bay Watershed Report

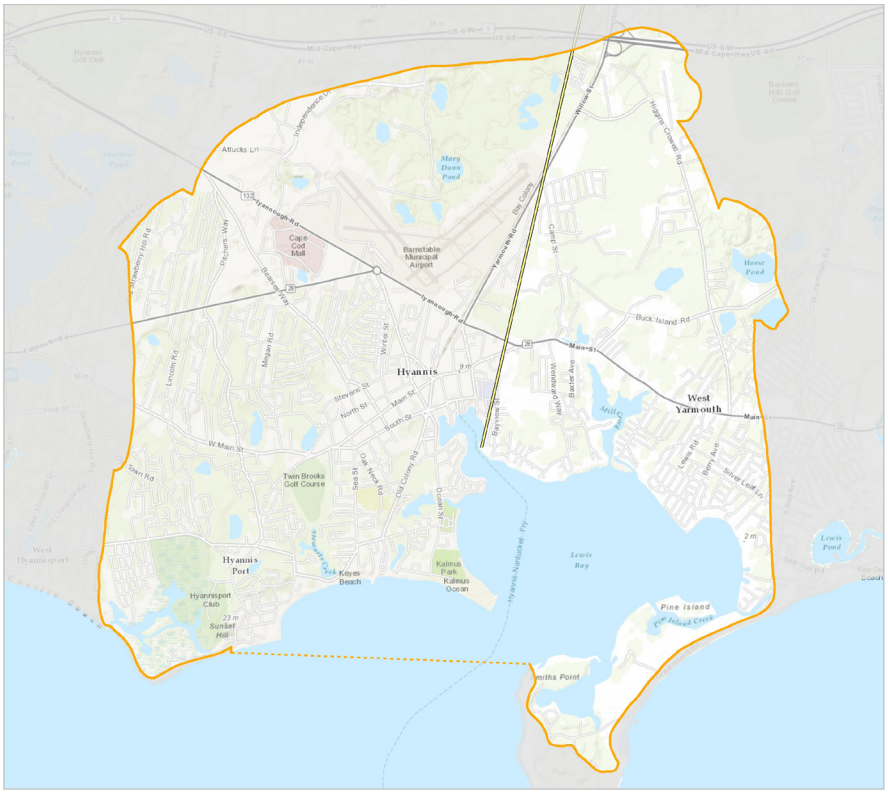
WATERSHED REPORT: MID CAPE

Lewis Bay

BARNSTABLE & YARMOUTH

WATER THREAT LEVEL

MODERATE



Lewis Bay Watershed

Introduction to the Watershed Reports

In 2001, the Massachusetts Estuaries Project (MEP) was established to evaluate the health of 89 coastal embayment ecosystems across southeastern Massachusetts. A collaboration between coastal communities, the Massachusetts Department of Environmental Protection (MassDEP), the School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth, the US Environmental Protection Agency (US EPA), the United States Geological Survey (USGS), the Massachusetts Executive Office of Energy and Environmental Affairs (EEA), and the Cape Cod Commission, the purpose of the MEP is to identify nitrogen thresholds and necessary nutrient reductions to support healthy ecosystems.

The Cape Cod 208 Plan Update, certified and approved by the Governor of the Commonwealth of Massachusetts and the US EPA in 2015, provides an opportunity and a path forward to implement responsible plans for the restoration of the waters that define Cape Cod.

On Cape Cod there are 53 embayment watersheds with physical characteristics that make them susceptible to nitrogen impacts. In its 2003 report, "The Massachusetts Estuaries Project – Embayment Restoration and Guidance for Implementation Strategies", MassDEP identifies the 46 Cape Cod embayments included in the

MEP. Thirty-three embayments studied to date require nitrogen reduction to achieve healthy ecosystem function. A Total Maximum Daily Load (TMDL) has been established (or a draft load has been identified and is under review) for these watersheds. For those embayments not studied, the 208 Plan Update recommends planning for a 25% reduction in nitrogen, as a placeholder, until information becomes available.

The 208 Plan Update directs Waste Treatment Management Agencies (WMAs) to develop watershed reports within 12 months of certification of the Plan Update. The Watershed Reports outline potential "bookend" scenarios for each watershed that include two scenarios to meet water quality goals in the watershed – a traditional scenario, which relies completely on the typical collection and centralized treatment of wastewater, and a non-traditional scenario, which uses remediation, restoration, and on-site reduction techniques to remove nutrients from raw and treated wastewater, groundwater and affected waterbodies.

The intent of the Watershed Reports is to outline two distinct approaches for addressing the nutrient problem. The reports are not intended to identify preferred and detailed plans for each watershed, but to facilitate discussions regarding effective and efficient solutions, particularly in watersheds shared by more than one town. In some cases, towns have provided information on collection areas and non-traditional technologies that have been specifically considered by that town.

The 208 Update developed a regionally consistent database of the nitrogen load entering each watershed. This data set includes estimates of wastewater, stormwater and fertilizer loads - similar to methodologies used by the MEP. Using this regionally consistent database, the Watershed MVP tool (wMVP) was developed so that different strategies (i.e., bookend scenarios) to reduce excess nitrogen load could be evaluated. The Watershed Reports use the MEP recommendations for the required nitrogen load reductions necessary to meet the threshold loads (that serve as the basis for nitrogen management), and then use the wMVP and the regionally consistent database values to develop bookend scenarios. There are variations of load between the MEP and wMVP, primarily due to differences in comparing older and newer databases.

Terms Defined

Total nitrogen load: the nitrogen load from the watershed contributed by septic, wastewater, fertilizer, stormwater, golf course, landfill, and natural sources.

Attenuated nitrogen load: the nitrogen load from the watershed that reaches the embayment after the effect of natural attenuation in wetlands, ponds or streams.

Threshold: the amount of nitrogen that a water body can receive from its watershed and still meet water quality goals; this number is based on MEP technical reports or Total Maximum Daily Load (TMDL) reports.

Reduction target: an approximation of the amount of nitrogen that needs to be removed from the watershed to achieve the threshold; this number is calculated by subtracting the threshold number from the attenuated total watershed load, and is for planning purposes only.

Percent contribution: the percent of attenuated nitrogen load that a town contributes to the watershed.

Kilogram responsibility: is calculated by applying the percent contribution to the reduction target and indicates the amount of nitrogen, in kg, that a community is responsible for addressing.

Total Maximum Daily Load: a regulatory term in the Clean Water Act, describing a value of the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards. Establishing a TMDL is necessary when a water body has been listed on the 303D list of impaired waters.

Lewis Bay

BARNSTABLE & YARMOUTH

WATER THREAT LEVEL
MODERATE

The Lewis Bay estuary and embayment system shoreline is located in the Towns of Barnstable and Yarmouth. It is comprised of several primary segments that include Hyannis Inner Harbor, Mill Creek, Snows Creek and Stewarts Creek. Lewis Bay is guarded by Great Island which contains Uncle Roberts Cove and Pine Island Creek. The Bay supports commercial fishing and a variety of recreational uses including boating, swimming, shell fishing and fin fishing.

The Problem

The Massachusetts Estuaries Project (MEP) technical report (available at http://www.mass.gov/eea/agencies/massdep/water/watersheds/the-massachusetts-estuaries-project-and-reports.html) indicates that the Lewis Bay system exceeds its critical threshold for nitrogen, resulting in impaired water quality. A MEP technical report has been completed and a Total Maximum Daily Load (TMDL) for nitrogen has been developed and approved. The MEP technical report indicates that the cause of eutrophication to the system is excess nitrogen from the contributing watershed.

- **MEP TECHNICAL REPORT STATUS:** Final
- **TMDL STATUS:** Final TMDL issued March 3, 2015 www.mass.gov/eea/docs/dep/water/resources/a-thru-m/lewisbay.pdf

Watershed nitrogen load characteristics were published in the 2008 MEP report for Lewis Bay, reflecting current conditions at the time of writing:

- **TOTAL ATTENUATED NITROGEN LOAD:** 48,877 Kg/Y (MEP Chapter VIII)
- **SOURCES OF ATTENUATED WATERSHED NITROGEN LOAD:**
  - 63% Septic Systems
  - 6% Fertilizer
  - 9% Stormwater from Impervious Surfaces
  - 22% Wastewater Treatment Facilities

Since the MEP report, the Commission compiled the following updated water use and nitrogen loads using the regional wMVP database (see page 2), enabling a more current estimate of nitrogen loading. Towns have also submitted watershed characteristics that may differ from wMVP. Differences may be explained by different source years of water use data, or other assumptions. Both values are presented, when provided:

- **REGIONAL DATABASE (WMVP)**
  See figure on page 1 for watershed boundary delineation
  - Total Wastewater Flow: 1.1 BGY (billion gallons per year)
  - Treated Wastewater Flow: 657 MGY
  - Septic Flow: 475 MGY
  - Total Attenuated Nitrogen Load: 55,338 Kg/Y
- **TOWN OF YARMOUTH/CDM REPORTED VALUE**
  - Treated Wastewater Flow: 632 MGY

CONTRIBUTING TOWNS

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the

Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

- **BARNSTABLE:** 66%
- **YARMOUTH:** 34%

THE MEP RESTORATION SCENARIO:

- **WATERSHED TOTAL NITROGEN REDUCTION TARGET:** 27%
- **WATERSHED SEPTIC REDUCTION TARGET:** 39% (The scenario represents the aggregated sub-embayment percent removal targets from the MEP technical report)

LEWIS BAY ESTUARY

- **EMBAYMENT AREA:** 1,737 acres
- **EMBAYMENT VOLUME:** 452 million cubic feet
- **2014 INTEGRATED LIST STATUS:**
  - Snows Creek: Category 4a for fecal coliform
  - Lewis Bay: Category 4a, 5 for fecal coliform and estuarine bioassessments
  - Mill Creek: Category 5 for fecal coliform and nitrogen
  - Category 4a - TMDL is completed; Category 5 - Waters requiring a TMDL
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

LEWIS BAY WATERSHED

General watershed characteristics according to the current wMVP regional database (see figure on page 1 for watershed boundary) follow. Towns have also submitted watershed characteristics that may differ from wMVP. Differences may be explained by changes due to development in the intervening years, or other assumptions. Both values are presented, when provided:

- **WATERSHED CHARACTERISTICS**

Regional Database (wMVP):

- Acres: 8,704
- Parcels: 9,531
- Residential Parcels: 77%
- Parcel Density: 0.91 acres per parcel (approx.)

Town of Yarmouth/CDM Reported Values:

- Acres: 8,759
- Parcels: 8,805
- Residential Parcels: 84%
- Parcel Density: 0.99 acres per parcel (approx.)

Freshwater Sources

PONDS

- **IDENTIFIED SURFACE WATERS:** 71
- **NUMBER OF NAMED FRESHWATER PONDS:** 8
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 6
- **2014 INTEGRATED LIST STATUS:** None listed

Barnstable and Yarmouth have participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality. Barnstable completed a Pond Action Report as part of its 2012 Draft Comprehensive Wastewater Management Plan (CWMP).

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 6

Halls Creek:

- Average Flow: 1,185 cubic meters per day (m3/d)
- Average Nitrate Concentrations: 0.85 milligrams per liter (mg/L)

Stewarts Creek:

- Average Flow: 31,966 m3/d
- Average Nitrate Concentrations: 1.17 mg/L

Snow's Creek:

- Average Flow: 5,298 m3/d
- Average Nitrate Concentrations: 1.14 mg/L

Hospital Bog:

- Average Flow: 1,318 m3/d
- Average Nitrate Concentrations: 0.64 mg/L

Mill Pond:

- Average Flow: 15,655 m3/d
- Average Nitrate Concentrations: 0.61 mg/L

Chase Brook:

- Average Flow: 3,255 m3/d
- Average Nitrate Concentrations: 0.45 mg/L

Stream data from MEP technical report. Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

DRINKING WATER SOURCES

Town submitted watershed reports (by Yarmouth) included watershed characteristics that slightly differ from the regional database, both values are reported below.

- **WATER DISTRICTS:** 2
  - Hyannis Water Division
  - Yarmouth Water Department
- **GRAVEL PACKED WELLS:**

Regional Database Gravel Packed Wells: 22
- 12 have nitrate concentrations between 0 and 0.5 mg/L
- 4 have nitrate concentrations between 0.5 and 1 mg/L
- 3 have nitrate concentrations between 2.5 and 5 mg/L
- 3 have no nitrate concentration data

Town Reported Gravel Packed Wells: 14
- 11 have average nitrate concentrations between 0 and 1 mg/L
- 3 have no nitrate concentration data

- **SMALL VOLUME WELLS:** 0

Each of the Towns has acquired significant portions of land in their Zone IIs for water quality protection which together with adopted land use controls recommended from the 1978 Section 208 Plan has resulted in excellent water quality. The wells with high nitrate concentrations are coincident with high density development and indicative of septic and wastewater impacts to groundwater quality.

Drinking water data from Cape Cod Commission and MassDEP data sources – nitrate values obtained from drinking water wells are from 2009-2012. The state and federal drinking water limit for nitrate is 10 mg/L. The Cape Cod Commission nitrate loading standard is 5 mg/l.

Degree of Impairment and Areas of Need

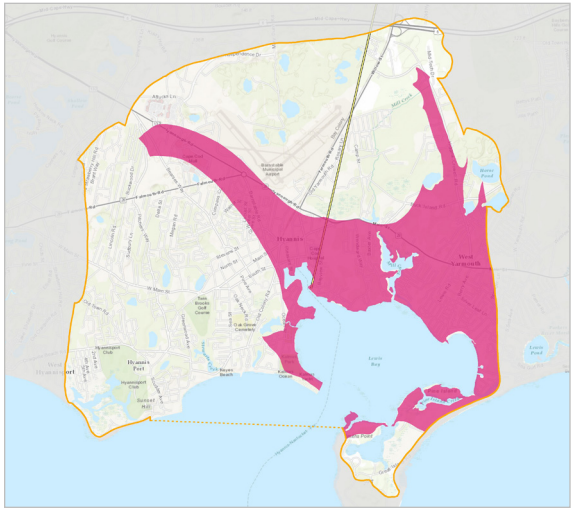
For the purposes of the Section 208 Plan Update areas of need are primarily defined by the amount of nitrogen reduction required as defined by the TMDL and/or MEP technical report. The aggregated watershed removal rates are 27% and 39% for total attenuated watershed and septic attenuated nitrogen loads, respectively. More specifically, the targeted amount of nitrogen reduction required by subwatershed ranges from 68% to 80% removal as indicated in the figures, Subwatersheds with Subwatersheds with Total and Septic Attenuated Nitrogen Removal Targets.

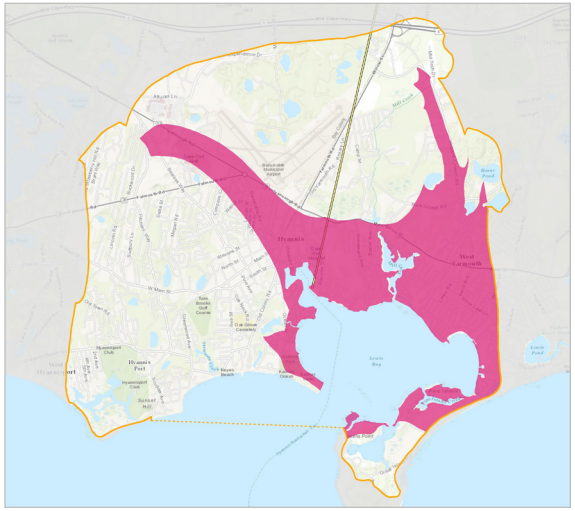
The Lewis Bay subwatershed in Yarmouth requires 80% septic nitrogen removal.

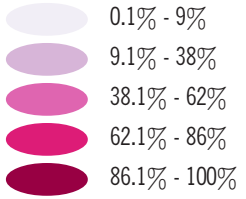
The nitrogen load from the watershed exceeds the threshold for Lewis Bay, resulting in impaired water quality. The upper headwaters of Lewis Bay are particularly impaired. The ecological health of a water body is determined from water quality, extent of eelgrass, assortment of benthic fauna, and dissolved oxygen and ranges from severe degradation, significantly impaired, moderately impaired, or healthy habitat conditions.

ECOLOGICAL CHARACTERISTICS AND WATER QUALITY

The MEP report provides the following characterization of the estuary's health:







Subwatersheds with
Total Attenuated Watershed Removal Targets

(Left) Benthic and atmospheric loads directly on embayments are not included.

Subwatersheds with
Septic Attenuated Nitrogen Removal Targets

(Right)

WATERSHED REPORT: Lewis Bay

- **OVERALL ECOLOGIC CONDITION:** Healthy to Significantly Impaired
- **OUTER LEWIS BAY:** Significantly Impaired
- **INNER LEWIS BAY:** Significantly Impaired
- **UNCLE ROBERTS COVE:** Significantly Impaired
- **HYANNIS INNER HARBOR:** Moderately Impaired
- **MILL CREEK:** Moderately Impaired
- **HALLS CREEK:** Healthy
- **SENTINEL STATION:**
  - Total Nitrogen Concentration Threshold: 0.378 mg/L
  - Total Nitrogen Concentration Existing: 0.407 mg/L (As reported at the MEP sentinel water-quality monitoring station)

This page intentionally left blank.

Traditional & Non-Traditional Scenarios

SCENARIO DEVELOPMENT

Through the 208 Stakeholder process, the Commission developed "bookend" scenarios – one looking at a possible solution using traditional collection and treatment, the other examining a possible suite of non-traditional technologies – to address the nitrogen management needs in each watershed. These bookend scenarios provide guidance for communities as they continue to discuss alternatives, priorities, and opportunities for identifying well-considered solutions that will address communities' needs and interests.

REGIONAL DATA

In preparation for this effort, the Commission collected regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used are 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water supplier and based on best available data. This approach allows for regionally consistent watershed scenario development.

WATERSHED SCENARIOS

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of residential load that would need to be collected if a traditional collection system and treatment facility was implemented. The pie charts show the load to be collected for treated effluent disposal both inside and outside the watershed.

Site specific analyses of collection areas may result in the need to collect wastewater from more or fewer parcels to meet the nitrogen reduction target. The scenarios presented are conceptual and are meant to inform discussions regarding effective and efficient solutions; they are not specific recommendations and should be viewed as resource information for additional and more detailed wastewater management planning.

In Lewis Bay, the Towns of Barnstable and Yarmouth have done additional and more detailed planning. Included in the last section of this report is a description of their efforts, along with details of plans developed to date.

TOTAL ATTENUATED WATERSHED NITROGEN LOAD VALUES (FROM WMVP)

Lewis Bay Nitrogen Sources	Total Attenuated Watershed Nitrogen Load (kg-N/yr)
Wastewater[1]	42,815
Fertilizer[2]	3,389
Stormwater	8,029
Other[3]	1,105
TOTAL WATERSHED LOAD	55,338
Total Watershed Threshold	35,705
TOTAL ATTENUATED LOAD TO BE REMOVED	19,633

1. Includes nitrogen loads from septic systems and wastewater treatment facilities. 2. Includes nitrogen loads from lawns, cranberry bogs, and golf courses. 3. Includes nitrogen loads from landfills and atmospheric deposition to vacant land.

The attenuated watershed loads, threshold, and both traditional and non-traditional scenarios presented in this report exclude Halls Creek because Halls Creek has its own

Traditional & Non-Traditional Scenarios

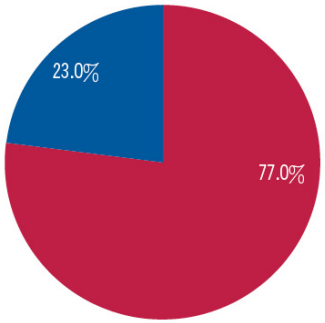
Non-Traditional

UNIT OF APPLIED TECHNOLOGY	ATTENUATED NITROGEN REMOVED IN KG/Y
25 % Nitrogen Reduction - Fertilizer Management	847
25 % Nitrogen Reduction - Stormwater Mitigation	2,007
1 Acres - Constructed Wetlands (Collection System)	500
15,200 Linear Feet - Permeable Reactive Barrier (PRB) (Capture load calculated by wMVP: 12,106.2 kg/Y)	8,777
38 Acres - Aquaculture/Oyster Beds	9,570
TOTAL	**21,701**

A summary of the approach and methodology that was applied using non-traditional technologies follows at the end of this report.

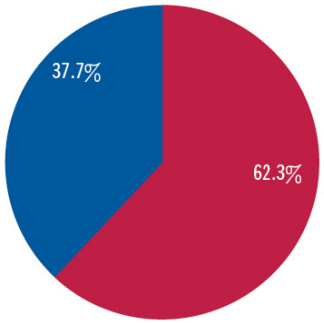
Traditional

CENTRALIZED TREATMENT WITH DISPOSAL INSIDE THE WATERSHED

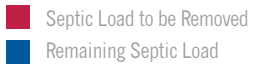


Assumes load to be collected and treated is disposed in the watershed, requiring additional collection to offset the load.

CENTRALIZED TREATMENT WITH DISPOSAL OUTSIDE THE WATERSHED



Assumes that the load to be collected and treated is removed from the watershed so no offset is required.



Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion. Those scenarios are included in this report.

Barnstable is also working closely with Mashpee and Sandwich on a watershed permit for the Popponesset Bay watershed.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

Since the approval of the 208 Plan Update, the Commission has been working for several months with Barnstable and Yarmouth to develop a targeted watershed scope of work for the Lewis Bay watershed to address excess nitrogen entering the system. In addition, the town was a recipient of a technical assistance grant through the Southeast New England Coastal Watershed Restoration Program (SNEP) and a stormwater best

management practice (BMP) was constructed in the Lewis Bay watershed in the spring of 2015.

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Town of Yarmouth Local Progress

In 2010, the Town of Yarmouth submitted its Comprehensive Wastewater Management Plan (CWMP) as a Draft Environmental Impact Report (DEIR). The draft CWMP targeted areas that would require wastewater collection to restore water quality in the Lewis Bay and Parkers River watersheds and deal with the Title 5 constraints on economic redevelopment in the area of Route 28. The town's plan included approximately 125 miles of sewer lines and the collection of 2.75 million gallons per day (MGD) of wastewater to be treated at a single facility in the Parkers River watershed. The project would ultimately serve 9,580 properties by 2035. Phase 1 of the plan would begin with the treatment facility and main trunk line sewer to serve Route 28 and portions of the Parkers River and Lewis Bay watershed.

The plan relies on gravity, pressure, and vacuum sewers. The MEP nitrogen reduction goals were the primary factor in choosing sewering locations. The phasing of these sewered areas also takes the town's economic goals into consideration.

The town submitted its Final Environmental Impact Report (FEIR) and received Massachusetts Environmental Policy Act (MEPA) approval in July 2011, but did not complete the Cape Cod Commission Development of Regional Impact (DRI) process before going to September 2011 Town Meeting to seek Phase 1 design and construction funds. Phases 1 through 5 were scheduled to be implemented over a 25-year period. The estimated cost of the total plan was $275 million. The first phase had an estimated cost of $55 million. Town Meeting did not approve the expenditure. The town withdrew the CWMP from the DRI review process.

Wastewater planning in the community had effectively come to a stop prior to the development of the 208 Plan Update.

In January 2016 town staff met with the Board of Selectmen to discuss a new financing plan for implementation of a program that would meet water quality standards in all of their watersheds.

The recommended plan includes a combination of traditional sewering methods with centralized treatment facilities as well as non-traditional nitrogen management options including a permeable reactive barrier (PRB) at the Buck Island Road effluent recharge site. The Town of Yarmouth is proposing a phased wastewater program that includes a collection system, a conveyance system and a centralized treatment facility, each constructed over several years. In addition to the proposed sewering, the recommended plan involves public outreach to promote nitrogen reduction and to prevent sewer system inflow, zoning modifications for growth management and establishment of the activity centers, development of sewer ordinances, and continued maintenance of Title 5 and I/A systems in the northern and western areas of the town that will not be served by the proposed wastewater collection system. The town also plans to implement stormwater and fertilizer improvement programs. As suggested in the 208 Plan Update, up to a 25% nitrogen reduction credit can be obtained by towns that implement stormwater and fertilizer management programs to reduce nitrogen contributions to each watershed. To achieve a 25% nitrogen reduction from stormwater in the Lewis Bay watershed, 50% of the total roads in the watershed are assumed to require stormwater best management practices (BMPs). Yarmouth plans to achieve 25% nitrogen reduction in fertilizers by implementing a town-wide fertilizer education program.

During the spring 2016 town meeting, the town approved $200,000 for additional CWMP planning.

In April 2016, Yarmouth submitted a request for assistance to continue CWMP development and town staff met with the Commission to discuss the request in early May.

In June 2016, Yarmouth received $35,000 from the Commission for the Towns of Dennis, Harwich and Yarmouth for a regional treatment facility cost study. Funding was part of $142,149 in local grants made by the Commission in support of 208 Plan implementation.

At the Spring 2017 Town Meeting appropriated $200,000 for wastewater planning and engineering services including engineering studies and evaluation of recharge sites; updating, modification, and pre-implementation services for the Comprehensive Wastewater Management Plan and support for related filings with the Massachusetts Environmental Policy Act office and the Cape Cod Commission.

Town of Yarmouth Watershed Scenario Details

Lewis Bay	CREDITS		REDUCTION TECHNOLOGIES			REMEDIATION AND RESTORATION TECHNOLOGIES			REMOVAL
NAME OF TECHNOLOGY	% Nitrogen Reduction	Load Reduction (kg-N/yr)	# Properties / Units	Flow Collected (gpd)	Load Reduction (kg-N/yr)	# Units Proposed	Unit Metric	Load Reduction (kg-N/yr)	Total Scenario Load Reduction (kg-N/yr)
Traditional Scenario									13,800**
Fertilizer Management	25%	Not reported**							
Stormwater Mitigation	25%	Not reported**							
Centralized Sewer			2,209	582,376	13,800				

NOTES:

* Average daily flow collected includes buildout and estimated inflow and infiltration.

** This total value does not include fertilizer management and stormwater management credits which were not calculated as part of the recommended program. Values for both are shown in the Cape Cod Commission's Non-Traditional summary on pg. 9; however, these values are for all of Bass River Watershed. These credits will be built into the updated recommended plan for Yarmouth when the Notice of Project Change (NPC) is submitted for the Final CWMP.

September 2016 Watershed Scenario Map

Methodology for Selecting Non-Traditional Technology Scenarios

- **FERTIGATION WELLS:** Golf courses were mapped to identify areas where fertigation wells could be utilized to recapture nitrogen-enriched groundwater and re-apply it to the managed turf areas to serve both irrigation and fertilization needs. Most golf courses were assumed to be eighteen holes with a fertilized area of 75 acres. Fertigation water was assumed to have an average concentration of 5 mg/liter. An uptake/attenuation rate of 80% was applied resulting in an assumed nitrogen reduction of 300 kg/year for each golf course with effectively located fertigation wells. In some cases other irrigated areas (such as athletic fields and cemeteries) were identified as potential fertigation locations. A nitrogen removal rate of 4 kg/Y/acre was used.

The MVP tool and other site-specific tools were utilized to quantify nitrogen load reductions for several potential NT interventions.

- **PERMEABLE REACTIVE BARRIERS:** for each PRB that was identified during the prior GIS-screening process an approximate capture area was identified using available water table maps and the wMVP tool. Upgradient contributing areas were digitized within wMVP and the nitrogen load was calculated. A nitrogen reduction of 72.5% was applied (calculated as an average of the reported attenuation range from the Technologies Matrix).
- **CONSTRUCTED WETLANDS (WITH COLLECTION):** Constructed wetlands were considered as a tertiary, polishing treatment for existing wastewater treatment plants. This included small-scale wastewater treatment systems. A nitrogen removal rate of 500 kg/Y/acre was used.
- **AQUACULTURE/OYSTER REEFS:** Potential areas for aquaculture and/or oyster reef restoration were considered based upon discussions with town representatives and review of maps to identify potential areas for these operations without significant conflicts to navigation. In some cases actual recent aquaculture expansions were included where they were developed after the MEP reports were prepared. An assumption of 1 million oysters per acre was used with a nitrogen removal rate of 250 kg/Y/acres.
- **FLOATING CONSTRUCTED WETLANDS:** Potential areas for floating wetlands were considered in areas where no conflicts with navigation or swimming areas were identified. A nitrogen removal rate of 0.4 kg/Y/sq foot was used.
- **INLET WIDENING AND COASTAL HABITAT RESTORATION:** Only considered in areas where these projects were identified by towns or state agencies and where detailed hydrologic investigations and modeling had been performed due to wide variations in nitrate load reduction, flushing impacts, impacts on flooding, and costs (dredging only, replacing infrastructure, removing and replacing roadways or bridges, etc.). Nitrogen removal rates were based on MEP or other studies.
- **INNOVATIVE & ALTERNATIVE SEPTIC SYSTEMS AND ECOTOILETS:** In most cases specific locations for these technologies were not identified. Rather general estimates for the percent adoption were provided based upon discussions with the stakeholder groups and their views on potential adoption rates. In some watersheds a 5% adoption rate was included based upon this stakeholder input. In a limited number of instances specific locations for these technologies were included based upon town input and suggestions. A nitrogen removal rate of 1.658 kg/Y for each system was used for I&A Septic Systems, and 2.984 kg/Y for enhanced I&A systems. A removal rate of 2.542 kg/Y was used for each home installation of an Ecotoilet, and 0.467 kg/Y for installation of urine diversion toilets in public settings.

Finally, the locations of specific technologies were discussed during the 208 stakeholder engagement process. Stakeholders across the Cape 'groundtruthed' potential NT locations and NT scenarios were adjusted accordingly.

Methodology for Selecting Non-Traditional Technology Scenarios

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology were derived from the Technologies Matrix. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology are noted below, based on the Technologies Matrix or newer data. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

Regional credits were developed for potential stormwater retrofits and fertilizer reductions. They were calculated as a percent reduction of existing nitrogen loads as identified in the MEP reports and updated GIS data developed by the Cape Cod Commission.

- **STORMWATER MANAGEMENT:** Most Cape communities have already begun the process of identifying significant untreated stormwater discharges and developing appropriate mitigation projects. With the prospect of the MS4 regulatory requirements it was assumed that additional mitigation efforts would be implemented. Based upon the evidence developed by the University of New Hampshire Stormwater Center that several vegetated stormwater management practices (including bioretention and constructed wetlands) are able to achieve nitrogen reductions of 50% or more and the assumption that only a portion (estimated at 50%) of identified sites would be retrofitted a 25% nitrogen reduction credit was assumed for each watershed. Specific locations and number of locations were not identified; this was deferred to individual towns to consider as part of the suite of nitrogen management strategies.
- **FERTILIZER REDUCTIONS:** Based upon the success of most Cape Cod towns to implement either regulatory or non-regulatory fertilizer management programs and the efforts of the Cape Cod Extension Service in educating homeowners a 25% reduction in fertilizer applications was assumed for each watershed.

Regional GIS screening methods were developed to identify locations for some non-traditional technologies. A GIS viewer was developed as an on-line tool for staff and consultants to utilize during the watershed planning process.

- **CONSTRUCTED WETLANDS/ PHYTOREMEDIATION:** A GIS-based screening method was developed by the Cape Cod Commission to identify and rank parcels of land that have potential for the location of constructed wetlands and phytoremediation. The ranking utilized parcel size and ownership, depth to groundwater, suitable soils, distance from wetlands, and undeveloped parcels. A nitrogen removal rate of 500 kg/Y/acre and 532 kg/Y/acre was used for Constructed Wetlands and Phytoremediation, respectively.
- **PERMEABLE REACTIVE BARRIERS (PRBS):** A GIS-based screening method was developed to identify existing roads that are proximate to receiving waters, downgradient of high density development, run perpendicular to groundwater flow (to have the highest potential to intercept nutrients in groundwater), and where the depth to groundwater is relatively shallow to maximize the area of saturated thickness treated in the aquifer.

Three Bays Watershed

Introduction to the Watershed Reports

In 2001, the Massachusetts Estuaries Project (MEP) was established to evaluate the health of 89 coastal embayment ecosystems across southeastern Massachusetts. A collaboration between coastal communities, the Massachusetts Department of Environmental Protection (MassDEP), the School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth, the US Environmental Protection Agency (US EPA), the United States Geological Survey (USGS), the Massachusetts Executive Office of Energy and Environmental Affairs (EEA), and the Cape Cod Commission, the purpose of the MEP is to identify nitrogen thresholds and necessary nutrient reductions to support healthy ecosystems.

The Cape Cod 208 Plan Update, certified and approved by the Governor of the Commonwealth of Massachusetts and the US EPA in 2015, provides an opportunity and a path forward to implement responsible plans for the restoration of the waters that define Cape Cod.

On Cape Cod there are 53 embayment watersheds with physical characteristics that make them susceptible to nitrogen impacts. In its 2003 report, "The Massachusetts Estuaries Project – Embayment Restoration and Guidance for Implementation Strategies", MassDEP identifies the 46 Cape Cod embayments included in the

MEP. Thirty-three embayments studied to date require nitrogen reduction to achieve healthy ecosystem function. A Total Maximum Daily Load (TMDL) has been established (or a draft load has been identified and is under review) for these watersheds. For those embayments not studied, the 208 Plan Update recommends planning for a 25% reduction in nitrogen, as a placeholder, until information becomes available.

The 208 Plan Update directs Waste Treatment Management Agencies (WMAs) to develop watershed reports within 12 months of certification of the Plan Update. The Watershed Reports outline potential "bookend" scenarios for each watershed that include two scenarios to meet water quality goals in the watershed – a traditional scenario, which relies completely on the typical collection and centralized treatment of wastewater, and a non-traditional scenario, which uses remediation, restoration, and on-site reduction techniques to remove nutrients from raw and treated wastewater, groundwater and affected waterbodies.

The intent of the Watershed Reports is to outline two distinct approaches for addressing the nutrient problem. The reports are not intended to identify preferred and detailed plans for each watershed, but to facilitate discussions regarding effective and efficient solutions, particularly in watersheds shared by more than one town. In some cases, towns have provided information on collection areas and non-traditional technologies that have been specifically considered by that town.

The 208 Update developed a regionally consistent database of the nitrogen load entering each watershed. This data set includes estimates of wastewater, stormwater and fertilizer loads - similar to methodologies used by the MEP. Using this regionally consistent database, the Watershed MVP tool (wMVP) was developed so that different strategies (i.e., bookend scenarios) to reduce excess nitrogen load could be evaluated. The Watershed Reports use the MEP recommendations for the required nitrogen load reductions necessary to meet the threshold loads (that serve as the basis for nitrogen management), and then use the wMVP and the regionally consistent database values to develop bookend scenarios. There are variations of load between the MEP and wMVP, primarily due to differences in comparing older and newer databases.

Terms Defined

Total nitrogen load: the nitrogen load from the watershed contributed by septic, wastewater, fertilizer, stormwater, golf course, landfill, and natural sources.

Attenuated nitrogen load: the nitrogen load from the watershed that reaches the embayment after the effect of natural attenuation in wetlands, ponds or streams.

Threshold: the amount of nitrogen that a water body can receive from its watershed and still meet water quality goals; this number is based on MEP technical reports or Total Maximum Daily Load (TMDL) reports.

Reduction target: an approximation of the amount of nitrogen that needs to be removed from the watershed to achieve the threshold; this number is calculated by subtracting the threshold number from the attenuated total watershed load, and is for planning purposes only.

Percent contribution: the percent of attenuated nitrogen load that a town contributes to the watershed.

Kilogram responsibility: is calculated by applying the percent contribution to the reduction target and indicates the amount of nitrogen, in kg, that a community is responsible for addressing.

Total Maximum Daily Load: a regulatory term in the Clean Water Act, describing a value of the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards. Establishing a TMDL is necessary when a water body has been listed on the 303D list of impaired waters.

Three Bays

BARNSTABLE & SANDWICH

WATER THREAT LEVEL
HIGH

The Three Bays estuary and embayment system is located in the Town of Barnstable. It is comprised of three primary segments that include West Bay, North Bay and Cotuit Bay. Sub-systems include Prince's Cove that flows into North Bay, the Narrows that flows between North Bay and Cotuit Bay and Eel River that flows into West Bay. The embayment is guarded by Sampson's Island/Dead Neck which defines the inner Seapuit River waterway between Cotuit Bay and West Bay. Three Bays supports a variety of recreational uses including boating, swimming, shell fishing and fin fishing

The Problem

The Massachusetts Estuaries Project (MEP) technical report (available at http://www.mass.gov/eea/agencies/massdep/water/watersheds/the-massachusetts-estuaries-project-and-reports.html) indicates that the Three Bays system exceeds its critical threshold for nitrogen, resulting in impaired water quality. A MEP technical report has been completed and a Total Maximum Daily Load (TMDL) for nitrogen has been developed and approved.

- **MEP TECHNICAL REPORT STATUS:** Final
- **TMDL STATUS:** Final TMDL

Watershed nitrogen load characteristics were published in the 2006 MEP report, reflecting current conditions at the time of writing:

- **TOTAL ATTENUATED NITROGEN LOAD (MEP CHAPTER VIII):** 47,727 Kg/Y
- **SOURCES OF ATTENUATED WATERSHED NITROGEN LOAD:**
  - 85% Septic Systems
  - 10% Fertilizer
  - 5% Stormwater From Impervious Surfaces

Since the MEP report, the Commission compiled the following updated water use and nitrogen loads using the regional wMVP database, enabling a more current estimate of nitrogen loading (see figure on page 1 for watershed boundary delineation):

- **TOTAL WASTEWATER FLOW:** 528 MGY (million gal per year)
  - Treated Wastewater Flow: 8 MGY
  - Septic Flow: 520 MGY
- **TOTAL ATTENUATED NITROGEN LOAD (WMVP):** 46,221Kg/Y

CONTRIBUTING TOWNS

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

- **BARNSTABLE:** 93%
- **SANDWICH:** 7%
- **MASHPEE:** <1%*

*Under existing conditions, the load contributed by Mashpee is so small that reductions are not necessary at this time; however, growth management measures should be taken to ensure that the contribution does not increase. Contributions will be reevaluated at least every five years, based on updated data.

THE MEP RESTORATION SCENARIO

- **WATERSHED TOTAL NITROGEN REDUCTION TARGET:** 46%
- **WATERSHED SEPTIC REDUCTION TARGET:** 60%
  (The scenario represents the aggregated sub-embayment percent removal targets from the MEP technical report)

THREE BAYS ESTUARY

- **EMBAYMENT AREA:** 1,251 acres
- **EMBAYMENT VOLUME:** 429 million cubic feet
- **2014 INTEGRATED LIST STATUS:** Category 4a for nitrogen and fecal coliform
  - Category 4a: TMDL is completed
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

THREE BAYS WATERSHED

General watershed characteristics according to the current wMVP regional database (see figure on page 1 for watershed boundary) follow.

- **WATERSHED CHARACTERISTICS**
  - Acres: 12,458
  - Parcels: 7,670
  - % Developed Residential Parcels: 85%
  - Parcel Density: 1.6 acres per parcel (approx.)

Freshwater Sources

PONDS

- **IDENTIFIED SURFACE WATERS:** 54
- **NUMBER OF NAMED FRESHWATER PONDS:** 21
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 19
- **2014 INTEGRATED LIST STATUS:** 6 listed
  - Hamblin Pond
  - Lovells Pond
  - Middle Pond
  - Mystic Lake
  - Lawrence Pond
  - Shubael Pond

Barnstable has participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality.

The Town of Barnstable has completed a Pond Action Report as part of its 2012 draft Comprehensive Wastewater Management Plan (CWMP). In addition, the Town has worked with watershed associations to implement alum treatments for Hamblin and Mystic Ponds and Lovells Pond treatment is scheduled. The Town regularly treats several ponds with Sonar, an herbicide to combat invasive weeds.

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 2

  Marstons Mills River:
  - Average Flow: 16,000 cubic meters per day (m3/d)
  - Average Nitrate Concentrations: 0.48 milligrams per liter (mg/L)

  Little River:
  - Average Flow: 3,500 m3/d
  - Average Nitrate Concentrations: 0.86 mg/L

Stream data from MEP technical report. Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

DRINKING WATER SOURCES

- **WATER DISTRICTS:** 3
  - Sandwich Water District
  - Centerville-Osterville-Marstons Mills (COMM) Water District
  - Cotuit Water District
- **GRAVEL PACKED WELLS:** 26
  - 6 have nitrate concentrations between 0 and 0.5 mg/L
  - 7 have nitrate concentrations between 0.5 and 1 mg/L
  - 7 have nitrate concentrations between 1 and 2.5 mg/L
  - 2 have nitrate concentrations between 2.5 and 5 mg/L
  - 4 have no nitrate concentration data
- **SMALL VOLUME WELLS:** 9

Each of the water districts and land trusts have acquired significant portions of land in their Zone IIs for water quality protection which, together with adopted land use controls recommended from the 1978 Section 208 Plan, has resulted in excellent water quality.

Drinking water data from Cape Cod Commission and MassDEP data sources – nitrate values obtained from drinking water wells are from 2009-2012. The state and federal drinking water limit for nitrate is 10 mg/L. The Cape Cod Commission nitrate loading standard is 5 mg/l.

Degree of Impairment and Areas of Need

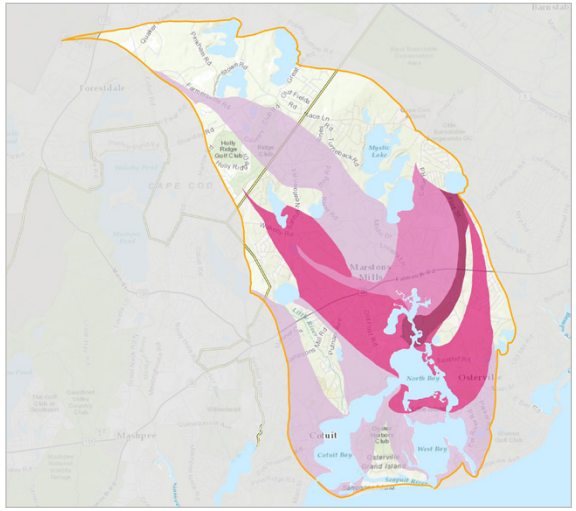
For the purposes of the Section 208 Plan Update areas of need are primarily defined by the amount of nitrogen reduction required as defined by the TMDL and/or MEP technical report. The aggregated watershed removal rates are 46% and 60% for total attenuated nitrogen and septic nitrogen, respectively. More specifically, the targeted amount of nitrogen reduction required by subwatershed ranges from 20 to 80% removal, as indicated in the figures, Subwatersheds with Total Attenuated Watershed Removal Targets and Subwatersheds with Septic Attenuated Nitrogen Removal Targets.

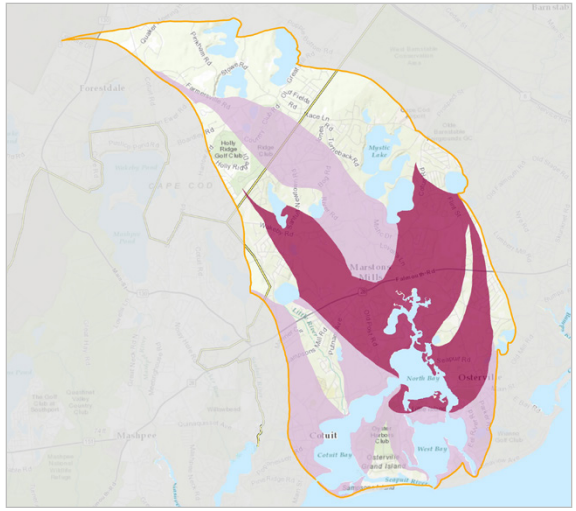
The nitrogen load from the watershed exceeds the TMDL for Three Bays, resulting in impaired water quality. The ecological health of a water body is determined from water quality, extent of eelgrass, assortment of benthic fauna, and dissolved oxygen and ranges from severe degradation, significantly impaired, moderately impaired, or healthy habitat conditions. The upper head waters of Three Bays are particularly impaired and the upper Prince Cove segment experiences occasional severe eutrophic conditions affecting recreational activities.

ECOLOGICAL CHARACTERISTICS AND WATER QUALITY

The MEP report provides the following characterization of the estuary's health:

- **OVERALL ECOLOGIC CONDITION:** Moderately Impaired to Severely Degraded
- **PRINCES COVE:** Significantly Impaired to Severely Degraded
- **WARRENS COVE:** Severely Degraded
- **UPPER NORTH BAY:** Significantly Impaired to Severely Degraded
- **LOWER NORTH BAY:** Moderately to Significantly Impaired
- **COTUIT BAY:** Moderately Impaired
- **WEST BAY:** Moderately Impaired
- **EEL POND:** Moderately to Significantly Impaired
- **SENTINEL STATION:**
  - Total Nitrogen Concentration Threshold: 0.38 mg/L
  - Total Nitrogen Concentration Existing: 0.5 mg/L (As reported at the MEP sentinel water-quality monitoring station)





0.1% - 9%
9.1% - 38%
38.1% - 62%
62.1% - 86%
86.1% - 100%

Subwatersheds with
Total Attenuated Watershed Removal Targets

(Left) Benthic and atmospheric loads directly on embayments are not included.

Subwatersheds with
Septic Attenuated Nitrogen Removal Targets

(Right)

Traditional & Non-Traditional Scenarios

SCENARIO DEVELOPMENT

Through the 208 Stakeholder process, the Commission developed "bookend" scenarios – one looking at a possible solution using traditional collection and treatment, the other examining a possible suite of non-traditional technologies – to address the nitrogen management needs in each watershed. These bookend scenarios provide guidance for communities as they continue to discuss alternatives, priorities, and opportunities for identifying well-considered solutions that will address communities' needs and interests.

REGIONAL DATA

In preparation for this effort, the Commission collected regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used are 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water supplier and based on best available data. This approach allows for regionally consistent watershed scenario development.

WATERSHED SCENARIOS

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of residential load that would need to be collected if a traditional collection system and treatment facility was implemented. The pie charts show the load to be collected for treated effluent disposal both inside and outside the watershed.

Site specific analyses of collection areas may result in the need to collect wastewater from more or fewer parcels to meet the nitrogen reduction target. The scenarios presented are conceptual and are meant to inform discussions regarding effective and efficient solutions; they are not specific recommendations and should be viewed as resource information for additional and more detailed wastewater management planning.

In Three Bays, the Towns of Barnstable and Sandwich have done additional and more detailed planning. Included in the last section of this report is a description of their efforts, along with details of plans developed to date.

TOTAL ATTENUATED WATERSHED NITROGEN LOAD VALUES (FROM WMVP)

Three Bays Nitrogen Sources	Total Attenuated Watershed Nitrogen Load (kg-N/yr)
Wastewater[1]	34,376
Fertilizer[2]	5,070
Stormwater	4,361
Other[3]	2,414
TOTAL WATERSHED LOAD	46,221
Total Watershed Threshold	25,643
TOTAL ATTENUATED LOAD TO BE REMOVED	20,578

1. Includes nitrogen loads from septic systems and wastewater treatment facilities.
2. Includes nitrogen loads from lawns, cranberry bogs, and golf courses.
3. Includes nitrogen loads from landfills and atmospheric deposition to vacant land.

Traditional & Non-Traditional Scenarios

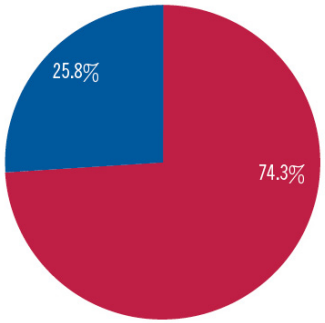
Non-Traditional

UNIT OF APPLIED TECHNOLOGY	ATTENUATED NITROGEN REMOVED IN KG/Y
25 % Nitrogen Reduction - Fertilizer Management	1,268
25 % Nitrogen Reduction - Stormwater Mitigation	1,090
3,000 Linear Feet - Permeable Reactive Barrier (PRB) (Capture load calculated by wMVP: 3,907.6 kg/Y)	2,833
225 Acres - Fertigation - Turf	660
66,000 Cubic Yards - Dredging/Inlet Widening	1,590
41 Acres - Aquaculture/Oyster Beds	10,200
4,700 Square Feet - Floating Constructed Wetlands	1,472
269 Units - Ecotoilets (UD & Compost)	684
336 People Per Year - UD School or Public Facility	157
TOTAL	**19,954**

A summary of the approach and methodology that was applied using non-traditional technologies follows at the end of this report.

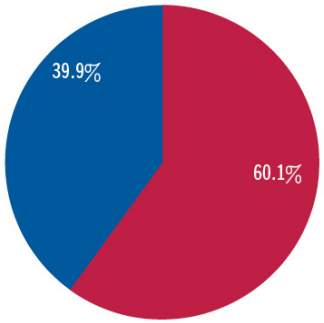
Traditional

CENTRALIZED TREATMENT WITH DISPOSAL INSIDE THE WATERSHED

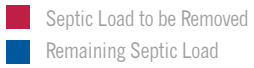


Assumes load to be collected and treated is disposed in the watershed, requiring additional collection to offset the load.

CENTRALIZED TREATMENT WITH DISPOSAL OUTSIDE THE WATERSHED



Assumes that the load to be collected and treated is removed from the watershed so no offset is required.



Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion. Those scenarios are included in this report.

Barnstable is also working closely with Mashpee and Sandwich on a watershed permit for the Popponesset Bay watershed.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

Throughout 2015 and 2016, Three Bays Preservation, Inc, worked with the Commission and town staff to develop conceptual plans for priority non-traditional projects within the Three Bays watershed. Detailed assessments of five priority projects were completed and designs were developed. The project sough to identify pilot projects where technologies could be implemented on a small scale and monitored to determine their effectiveness.

Town of Barnstable Watershed Scenario Details

Three Bays	CREDITS		REDUCTION TECHNOLOGIES			REMEDIATION AND RESTORATION TECHNOLOGIES			REMOVAL
NAME OF TECHNOLOGY	% Nitrogen Reduction	Load Reduction (kg-N/yr)	# Properties / Units	Flow Collected (gpd)	Load Reduction (kg-N/yr)	# Units Proposed	Unit Metric	Load Reduction (kg-N/yr)	Total Scenario Load Reduction (kg-N/yr)
Traditional Scenario									19,700
Centralized Sewer - Outside Disposal			3,930	710,000	19,700				
Non-Traditional Scenario									19,043
Fertilizer Management	25%	498							
Stormwater Mitigation	25%	1,008							
Permeable Reactive Barrier (PRB)						3,000	Linear Feet	2,833	
Fertigation - Golf Course						188	Acres	600	
Aquaculture/Oyster Beds						43	Acres	10,200	
Coastal Habitat Restoration						66,000	Cubic Yards	1,590	
Floating Constructed Wetlands						4,700	Square Feet	1,472	
Ecotoilets (UD & Compost)			113	Units	684				
UD School or Public Facility			69	People Per Year	157				

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Town of Sandwich Local Progress

The Town of Sandwich has an established water quality committee to oversee water quality and wastewater planning efforts. In October 2015 town staff and their consultant (Wright-Pierce) met with Cape Cod Commission staff to discuss watershed planning, decision support tools, and scenario development for Sandwich watersheds. In the same month the town was approached by Mashpee regarding approaches for Popponesset Bay, and a potential watershed permit, and has agreed to participate with Mashpee and Barnstable in this shared effort. It is expected that Barnstable, Mashpee, and Sandwich will collaborate on the first watershed permit in the region in close coordination with the Cape Cod Commission and the Massachusetts Department of Environmental Protection.

Previously the committee developed a scope of work for a Comprehensive Wastewater Management Plan (CWMP) and submitted the scope under the Sagamore Lens Natural Resource Damages Assessment, related to past groundwater contamination at the Textron facility at Joint Base Cape Cod (JBCC). The town received an award of $400,000 t0 conduct its water/wastewater plan and completed a comprehensive needs assessment, as well as an interim wastewater solutions plan to accommodate economic development in the South Sandwich Village Center.

The town spent several years working with a private developer on a development project that included a public-private wastewater component for the construction of a facility that would accommodate the private project, in addition to some public wastewater needs. That project will not be completed, but the town is again seeking a private partner to create new economic growth and to potentially participate in infrastructure development.

The town has participated in discussions at JBCC about the potential use of its existing wastewater infrastructure as a regional option for the Upper Cape towns.

In February 2016 the Town of Sandwich requested a meeting with Commission staff to discuss watershed scenarios and potential modifications to watersheds in which Sandwich has jurisdiction. The town provided collection footprints and assumptions for a single treatment facility to serve all three watersheds (Popponesset Bay, Three Bays, and Waquoit Bay), consistent with the Sandwich CWMP, and identified locations for non-traditional approaches, in addition to credits for stormwater and fertilizer reduction. The Town proposes a 25% fertilizer management credit and a 6.25% stormwater management credit. While the proposed interventions, alone, do not meet the nitrogen allocations identified in Appendix 8C of the 208 Plan Update, the town has expressed a preference to rely on nutrient trading or cost sharing to reduce the load allocated to the downgradient towns in the shared watersheds of Popponesset Bay, Three Bays and Waquoit Bay, where nitrogen reductions can be more cost effectively attained.

Town of Sandwich Watershed Scenario Details

Three Bays	CREDITS		REDUCTION TECHNOLOGIES			REMEDIATION AND RESTORATION TECHNOLOGIES			REMOVAL
NAME OF TECHNOLOGY	% Nitrogen Reduction	Load Reduction (kg-N/yr)	# Properties / Units	Flow Collected (gpd)	Load Reduction (kg-N/yr)	# Units Proposed	Unit Metric	Load Reduction (kg-N/yr)	Total Scenario Load Reduction (kg-N/yr)
Traditional Scenario									1,170
Centralized Sewer - Outside Disposal			780	162,623	1,170				
Non-Traditional Scenario*									410
Fertilizer Management	25%	35							
Stormwater Mitigation	6.25%	16							
Fertigation - Turf						75	Acres	118	
Golf Course Fertilizer Reduction						5,991	Pounds**	241	

NOTES:

* The Town of Sandwich will rely on nutrient trading as an additional measure to meet the TMDL, if necessary.

** Golf course fertilizer use was reduced by a total of 5,991 lbs/year (unattenuated), the corresponding nitrogen reduction is 241 kg/year (attenuated).

Methodology for Selecting Non-Traditional Technology Scenarios

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology were derived from the Technologies Matrix. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology are noted below, based on the Technologies Matrix or newer data. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

Regional credits were developed for potential stormwater retrofits and fertilizer reductions. They were calculated as a percent reduction of existing nitrogen loads as identified in the MEP reports and updated GIS data developed by the Cape Cod Commission.

- **STORMWATER MANAGEMENT:** Most Cape communities have already begun the process of identifying significant untreated stormwater discharges and developing appropriate mitigation projects. With the prospect of the MS4 regulatory requirements it was assumed that additional mitigation efforts would be implemented. Based upon the evidence developed by the University of New Hampshire Stormwater Center that several vegetated stormwater management practices (including bioretention and constructed wetlands) are able to achieve nitrogen reductions of 50% or more and the assumption that only a portion (estimated at 50%) of identified sites would be retrofitted a 25% nitrogen reduction credit was assumed for each watershed. Specific locations and number of locations were not identified; this was deferred to individual towns to consider as part of the suite of nitrogen management strategies.
- **FERTILIZER REDUCTIONS:** Based upon the success of most Cape Cod towns to implement either regulatory or non-regulatory fertilizer management programs and the efforts of the Cape Cod Extension Service in educating homeowners a 25% reduction in fertilizer applications was assumed for each watershed.

Regional GIS screening methods were developed to identify locations for some non-traditional technologies. A GIS viewer was developed as an on-line tool for staff and consultants to utilize during the watershed planning process.

- **CONSTRUCTED WETLANDS/ PHYTOREMEDIATION:** A GIS-based screening method was developed by the Cape Cod Commission to identify and rank parcels of land that have potential for the location of constructed wetlands and phytoremediation. The ranking utilized parcel size and ownership, depth to groundwater, suitable soils, distance from wetlands, and undeveloped parcels. A nitrogen removal rate of 500 kg/Y/acre and 532 kg/Y/acre was used for Constructed Wetlands and Phytoremediation, respectively.
- **PERMEABLE REACTIVE BARRIERS (PRBS):** A GIS-based screening method was developed to identify existing roads that are proximate to receiving waters, downgradient of high density development, run perpendicular to groundwater flow (to have the highest potential to intercept nutrients in groundwater), and where the depth to groundwater is relatively shallow to maximize the area of saturated thickness treated in the aquifer.

Methodology for Selecting Non-Traditional Technology Scenarios

- **FERTIGATION WELLS:** Golf courses were mapped to identify areas where fertigation wells could be utilized to recapture nitrogen-enriched groundwater and re-apply it to the managed turf areas to serve both irrigation and fertilization needs. Most golf courses were assumed to be eighteen holes with a fertilized area of 75 acres. Fertigation water was assumed to have an average concentration of 5 mg/liter. An uptake/attenuation rate of 80% was applied resulting in an assumed nitrogen reduction of 300 kg/year for each golf course with effectively located fertigation wells. In some cases other irrigated areas (such as athletic fields and cemeteries) were identified as potential fertigation locations. A nitrogen removal rate of 4 kg/Y/acre was used.

The MVP tool and other site-specific tools were utilized to quantify nitrogen load reductions for several potential NT interventions.

- **PERMEABLE REACTIVE BARRIERS:** for each PRB that was identified during the prior GIS-screening process an approximate capture area was identified using available water table maps and the wMVP tool. Upgradient contributing areas were digitized within wMVP and the nitrogen load was calculated. A nitrogen reduction of 72.5% was applied (calculated as an average of the reported attenuation range from the Technologies Matrix).
- **CONSTRUCTED WETLANDS (WITH COLLECTION):** Constructed wetlands were considered as a tertiary, polishing treatment for existing wastewater treatment plants. This included small-scale wastewater treatment systems. A nitrogen removal rate of 500 kg/Y/acre was used.
- **AQUACULTURE/OYSTER REEFS:** Potential areas for aquaculture and/or oyster reef restoration were considered based upon discussions with town representatives and review of maps to identify potential areas for these operations without significant conflicts to navigation. In some cases actual recent aquaculture expansions were included where they were developed after the MEP reports were prepared. An assumption of 1 million oysters per acre was used with a nitrogen removal rate of 250 kg/Y/acres.
- **FLOATING CONSTRUCTED WETLANDS:** Potential areas for floating wetlands were considered in areas where no conflicts with navigation or swimming areas were identified. A nitrogen removal rate of 0.4 kg/Y/sq foot was used.
- **INLET WIDENING AND COASTAL HABITAT RESTORATION:** Only considered in areas where these projects were identified by towns or state agencies and where detailed hydrologic investigations and modeling had been performed due to wide variations in nitrate load reduction, flushing impacts, impacts on flooding, and costs (dredging only, replacing infrastructure, removing and replacing roadways or bridges, etc.). Nitrogen removal rates were based on MEP or other studies.
- **INNOVATIVE & ALTERNATIVE SEPTIC SYSTEMS AND ECOTOILETS:** In most cases specific locations for these technologies were not identified. Rather general estimates for the percent adoption were provided based upon discussions with the stakeholder groups and their views on potential adoption rates. In some watersheds a 5% adoption rate was included based upon this stakeholder input. In a limited number of instances specific locations for these technologies were included based upon town input and suggestions. A nitrogen removal rate of 1.658 kg/Y for each system was used for I&A Septic Systems, and 2.984 kg/Y for enhanced I&A systems. A removal rate of 2.542 kg/Y was used for each home installation of an Ecotoilet, and 0.467 kg/Y for installation of urine diversion toilets in public settings.

Finally, the locations of specific technologies were discussed during the 208 stakeholder engagement process. Stakeholders across the Cape 'groundtruthed' potential NT locations and NT scenarios were adjusted accordingly.

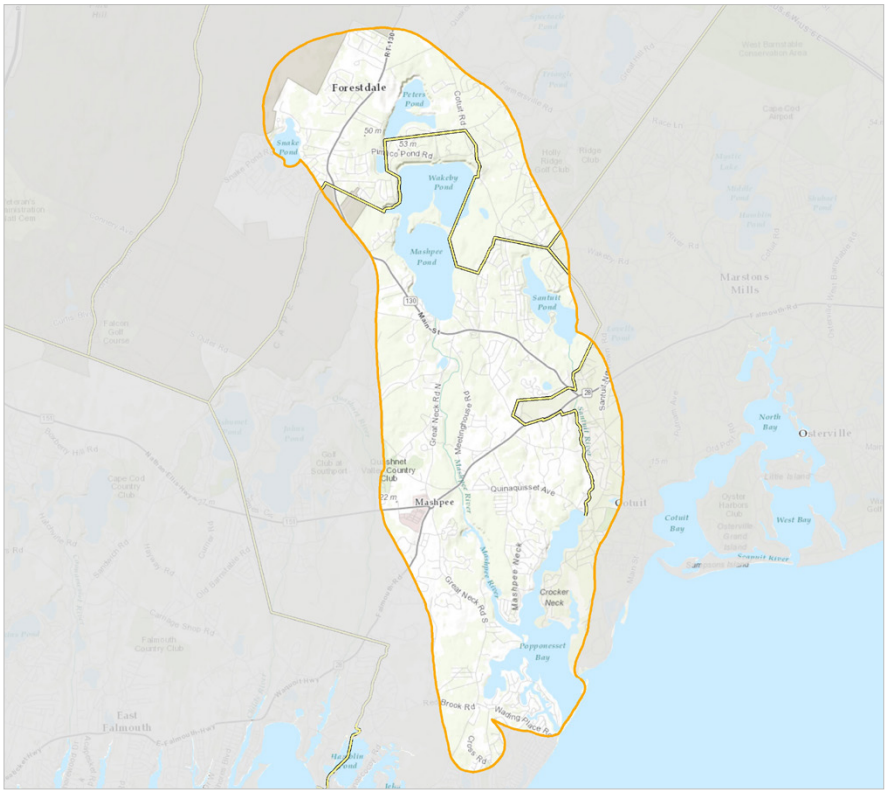
WATER THREAT LEVEL

HIGH



Popponesset Bay Watershed

Introduction to the Watershed Reports

In 2001, the Massachusetts Estuaries Project (MEP) was established to evaluate the health of 89 coastal embayment ecosystems across southeastern Massachusetts. A collaboration between coastal communities, the Massachusetts Department of Environmental Protection (MassDEP), the School of Marine Science and Technology (SMAST) at the University of Massachusetts-Dartmouth, the US Environmental Protection Agency (US EPA), the United States Geological Survey (USGS), the Massachusetts Executive Office of Energy and Environmental Affairs (EEA), and the Cape Cod Commission, the purpose of the MEP is to identify nitrogen thresholds and necessary nutrient reductions to support healthy ecosystems.

The Cape Cod 208 Plan Update, certified and approved by the Governor of the Commonwealth of Massachusetts and the US EPA in 2015, provides an opportunity and a path forward to implement responsible plans for the restoration of the waters that define Cape Cod.

On Cape Cod there are 53 embayment watersheds with physical characteristics that make them susceptible to nitrogen impacts. In its 2003 report, "The Massachusetts Estuaries Project – Embayment Restoration and Guidance for Implementation Strategies", MassDEP identifies the 46 Cape Cod embayments included in the

MEP. Thirty-three embayments studied to date require nitrogen reduction to achieve healthy ecosystem function. A Total Maximum Daily Load (TMDL) has been established (or a draft load has been identified and is under review) for these watersheds. For those embayments not studied, the 208 Plan Update recommends planning for a 25% reduction in nitrogen, as a placeholder, until information becomes available.

The 208 Plan Update directs Waste Treatment Management Agencies (WMAs) to develop watershed reports within 12 months of certification of the Plan Update. The Watershed Reports outline potential "bookend" scenarios for each watershed that include two scenarios to meet water quality goals in the watershed – a traditional scenario, which relies completely on the typical collection and centralized treatment of wastewater, and a non-traditional scenario, which uses remediation, restoration, and on-site reduction techniques to remove nutrients from raw and treated wastewater, groundwater and affected waterbodies.

The intent of the Watershed Reports is to outline two distinct approaches for addressing the nutrient problem. The reports are not intended to identify preferred and detailed plans for each watershed, but to facilitate discussions regarding effective and efficient solutions, particularly in watersheds shared by more than one town. In some cases, towns have provided information on collection areas and non-traditional technologies that have been specifically considered by that town.

The 208 Update developed a regionally consistent database of the nitrogen load entering each watershed. This data set includes estimates of wastewater, stormwater and fertilizer loads - similar to methodologies used by the MEP. Using this regionally consistent database, the Watershed MVP tool (wMVP) was developed so that different strategies (i.e., bookend scenarios) to reduce excess nitrogen load could be evaluated. The Watershed Reports use the MEP recommendations for the required nitrogen load reductions necessary to meet the threshold loads (that serve as the basis for nitrogen management), and then use the wMVP and the regionally consistent database values to develop bookend scenarios. There are variations of load between the MEP and wMVP, primarily due to differences in comparing older and newer databases.

Terms Defined

Total nitrogen load: the nitrogen load from the watershed contributed by septic, wastewater, fertilizer, stormwater, golf course, landfill, and natural sources.

Attenuated nitrogen load: the nitrogen load from the watershed that reaches the embayment after the effect of natural attenuation in wetlands, ponds or streams.

Threshold: the amount of nitrogen that a water body can receive from its watershed and still meet water quality goals; this number is based on MEP technical reports or Total Maximum Daily Load (TMDL) reports.

Reduction target: an approximation of the amount of nitrogen that needs to be removed from the watershed to achieve the threshold; this number is calculated by subtracting the threshold number from the attenuated total watershed load, and is for planning purposes only.

Percent contribution: the percent of attenuated nitrogen load that a town contributes to the watershed.

Kilogram responsibility: is calculated by applying the percent contribution to the reduction target and indicates the amount of nitrogen, in kg, that a community is responsible for addressing.

Total Maximum Daily Load: a regulatory term in the Clean Water Act, describing a value of the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards. Establishing a TMDL is necessary when a water body has been listed on the 303D list of impaired waters.

WATERSHED REPORT: UPPER CAPE

Popponesset Bay

MASHPEE, BARNSTABLE & SANDWICH

WATER THREAT LEVEL

HIGH

The Popponesset Bay estuary is located in the Towns of Mashpee and Barnstable. It is a large shallow embayment that extends from Nantucket Sound nearly three miles to its groundwater fed headwaters. The embayment includes four distinct sub-systems - Shoestring Bay, the Mashpee River, Ockway Bay and Popponesset Creek. The estuary supports a variety of recreational uses including boating, swimming, shell fishing and fin fishing.

The Problem

The Massachusetts Estuaries Project (MEP) technical report (available at http://www.mass.gov/eea/agencies/massdep/water/watersheds/the-massachusetts-estuaries-project-and-reports.html) indicates the Popponesset Bay system exceeds its critical threshold for nitrogen, resulting in impaired water quality. Popponesset Bay is one of the first to have received a MEP technical report. A MEP technical report has been completed and a Total Maximum Daily Load (TMDL) for nitrogen has been developed and approved.

- **MEP TECHNICAL REPORT STATUS:** Final
- **TMDL STATUS:** Final TMDL

Watershed nitrogen load characteristics were published in the 2004 MEP report, reflecting current conditions at the time of writing:

- **TOTAL ATTENUATED NITROGEN LOAD (MEP CHAPTER VIII):** 28,813 kg/Y
- **SOURCES OF ATTENUATED WATERSHED NITROGEN LOAD:**
  - 82% Septic Systems
  - 10% Fertilizer
  - 7% Stormwater From Impervious Surfaces
  - 1% Wastewater Treatment Facilities

Since the MEP report, the Commission compiled the following updated water use and nitrogen loads using the regional wMVP database, enabling a more current estimate of nitrogen loading (see figure on page 1 for watershed boundary delineation):

- **TOTAL WASTEWATER FLOW:** 456 MGY (million gal per year)
  - Treated Wastewater Flow: 61 MGY
  - Septic Flow: 395 MGY
- **TOTAL ATTENUATED NITROGEN LOAD (WMVP):** 31,961 kg/Y

CONTRIBUTING TOWNS

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

A portion of the land area in Sandwich and Mashpee is not in the control of the towns as it is part of Joint Base Cape Cod (JBCC), which is served by a wastewater treatment facility and discharged outside of the watershed.

- **MASHPEE:** 75%
- **BARNSTABLE:** 17%
- **SANDWICH:** 8%

The Towns of Barnstable, Mashpee, and Sandwich are currently working through the development of an Inter-Municipal Agreement (IMA) and draft watershed permit, and have developed updated percent contributions based on those efforts (Mashpee - 75%, Barnstable - 16%, Sandwich - 9%). The percentages agreed upon in the IMA will be the basis for the coordinated efforts of the three communities to address nitrogen impacts on Popponesset Bay.

THE MEP RESTORATION SCENARIO

- **WATERSHED TOTAL ATTENUATED NITROGEN REDUCTION TARGET:** 45%
- **WATERSHED SEPTIC REDUCTION TARGET:** 61%
  (The scenario represents the aggregated sub-embayment percent removal targets from the MEP technical report)

POPPONESSET BAY ESTUARY

- **EMBAYMENT AREA:** 720 acres
- **EMBAYMENT VOLUME:** 119 million cubic feet
- **2014 INTEGRATED LIST STATUS:** Category 4a for estuarine bioassessments and fecal coliform
  - Category 4a: TMDL is complete
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

POPPONESSET BAY WATERSHED

General watershed characteristics according to the current wMVP regional database (see figure on page 1 for watershed boundary) follow.

- **WATERSHED CHARACTERISTICS**
  - Acres: 13,082
  - Parcels: 7,979
  - % Developed Residential Parcels: 78%
  - Parcel Density: 1.6 acres per parcel (approx.)

Freshwater Sources

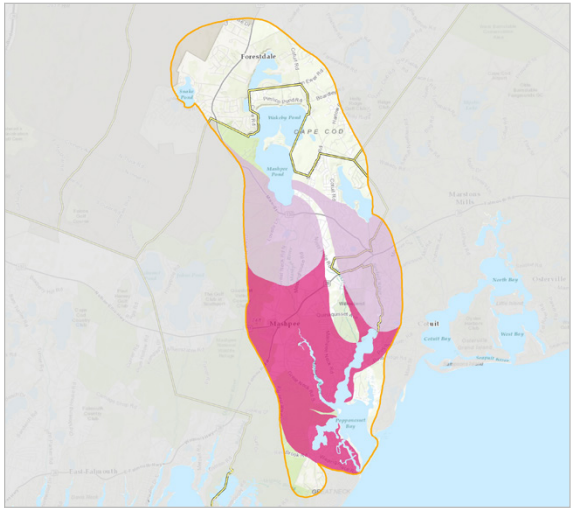
PONDS

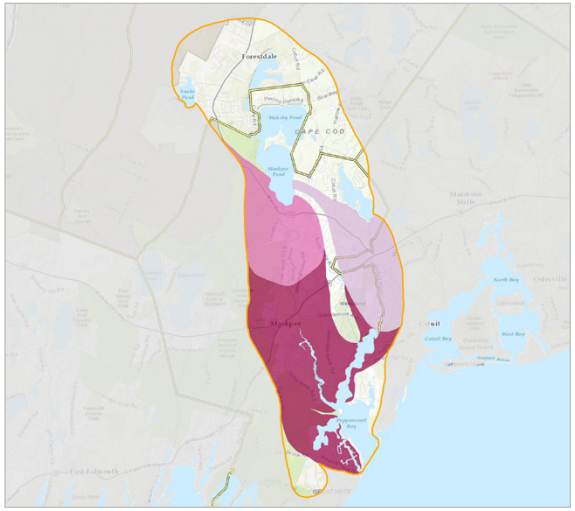
- **IDENTIFIED SURFACE WATERS:** 40
- **NUMBER OF NAMED FRESHWATER PONDS:** 13
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 5
- **2014 INTEGRATED LIST STATUS:** 4 listed

Mashpee recently conducted a pond assessment and installed Solar Bees in Santuit Pond in efforts to restore water quality. Mashpee and Barnstable have participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality.

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 2





0.1% - 9%
9.1% - 38%
38.1% - 62%
62.1% - 86%
86.1% - 100%

Subwatersheds with
Total Attenuated Watershed Removal Targets

(Left) Benthic and atmospheric loads directly on embayments are not included.

Subwatersheds with
Septic Attenuated Nitrogen Removal Targets

(Right)

Mashpee River:
- Average Flow: 26,223 cubic meters per day (m3/d)
- Average Nitrate Concentrations: .318 milligrams per liter (mg/L)

Santuit River:
- Average Flow: 13,164 m3/d
- Average Nitrate Concentrations: 0.702 mg/L

Stream data from MEP technical report. Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

DRINKING WATER SOURCES

- **WATER DISTRICTS:** 3
  - Sandwich Water District
  - Cotuit Water District
  - Mashpee Water District
- **GRAVEL PACKED WELLS:** 9
  - 2 have nitrate concentrations between 0 and 0.5 mg/L
  - 1 have nitrate concentrations between 0.5 and 1 mg/L
  - 3 have nitrate concentrations between 1 and 2.5 mg/L
  - 1 have nitrate concentrations between 2.5 and 5 mg/L
  - 2 have no nitrate concentration data
- **SMALL VOLUME WELLS:** 2

Drinking water data from Cape Cod Commission and MassDEP data sources – nitrate values obtained from drinking water wells are from 2009-2012. The state and federal drinking water limit for nitrate is 10 mg/L. The Cape Cod Commission nitrate loading standard is 5 mg/l.

The MEP report includes contributing areas to the Rock Landing community water supply wells in its watershed map. These wells are located outside the Popponesset Bay watershed.

Degree of Impairment and Areas of Need

For the purposes of the Section 208 Plan Update areas of need are primarily defined by the amount of nitrogen reduction required as defined by the TMDL and/or MEP technical report. These were referred to above as a 61% reduction in septic nitrogen and a 45% reduction in total nitrogen. More specifically, the MEP provides a targeted amount of nitrogen reduction required by subwatershed, as shown in the figures Subwatersheds with Total Attenuated Watershed Removal Targets and Subwatersheds with Septic Attenuated Nitrogen Removal Targets.

The nitrogen load from the watershed exceeds the threshold or TMDL for Popponesset Bay, resulting in impaired water quality. The ecological health of a water body is determined from water quality, extent of eelgrass, assortment of benthic fauna, and dissolved oxygen and ranges from severe degradation, significantly impaired, moderately impaired, or healthy habitat conditions

MEP ECOLOGICAL CHARACTERISTICS AND WATER QUALITY

The MEP report provides the following characterization of the estuary's health:

- **OVERALL ECOLOGIC CONDITION:** Healthy to Severely Degraded
- **LOWER POPPONESSET BAY:** Healthy to Moderately Impaired
- **OCKWAY BAY:** Significantly Impaired to Severely Degraded
- **MASHPEE RIVER:** significantly Impaired to Severely Degraded
- **SENTINEL STATION:**
  - Total Nitrogen Concentration Threshold: 0.38 mg/L
  - Total Nitrogen Concentration Existing: 0.45 mg/L (As reported at the MEP sentinel water-quality monitoring station)

Traditional & Non-Traditional Scenarios

SCENARIO DEVELOPMENT

Through the 208 Stakeholder process, the Commission developed "bookend" scenarios – one looking at a possible solution using traditional collection and treatment, the other examining a possible suite of non-traditional technologies – to address the nitrogen management needs in each watershed. These bookend scenarios provide guidance for communities as they continue to discuss alternatives, priorities, and opportunities for identifying well-considered solutions that will address communities' needs and interests.

REGIONAL DATA

In preparation for this effort, the Commission collected regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used are 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water supplier and based on best available data. This approach allows for regionally consistent watershed scenario development.

WATERSHED SCENARIOS

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of residential load that would need to be collected if a traditional collection system and treatment facility was implemented. The pie charts show the load to be collected for treated effluent disposal both inside and outside the watershed.

Site specific analyses of collection areas may result in the need to collect wastewater from more or fewer parcels to meet the nitrogen reduction target. The scenarios presented are conceptual and are meant to inform discussions regarding effective and efficient solutions; they are not specific recommendations and should be viewed as resource information for additional and more detailed wastewater management planning.

In Popponesset Bay, the Towns of Mashpee and Sandwich have done additional and more detailed planning. Included in the last section of this report is a description of their efforts, along with plan details. The Town of Mashpee scenario is based on their Final Recommended Plan and Final Environmental Impact Report established as part of their Watershed Nitrogen Management Planning efforts.

TOTAL ATTENUATED NITROGEN LOAD VALUES (FROM WMVP)

Popponesset Bay Nitrogen Sources	Total Attenuated Watershed Nitrogen Load (kg-N/yr)
Wastewater[1]	22,729
Fertilizer[2]	3,571
Stormwater	4,143
Other[3]	1,518
TOTAL WATERSHED LOAD	31,961
Total Watershed Threshold	13,852
TOTAL ATTENUATED LOAD TO BE REMOVED	18,109

1. Includes nitrogen loads from septic systems and wastewater treatment facilities.
2. Includes nitrogen loads from lawns, cranberry bogs, and golf courses.
3. Includes nitrogen loads from landfills and atmospheric deposition to vacant land.

Traditional & Non-Traditional Scenarios

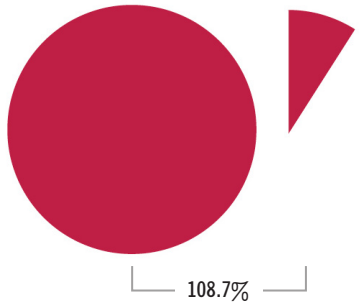
Non-Traditional

UNIT OF APPLIED TECHNOLOGY	ATTENUATED NITROGEN REMOVED IN KG/Y
25 % Nitrogen Reduction - Fertilizer Management	893
25 % Nitrogen Reduction - Stormwater Mitigation	1,036
4,000 Linear Feet - Permeable Reactive Barrier (PRB) (Capture load calculated by wMVP: 3,492.4 kg/Y)	2,532
233 Acres - Fertigation - Turf	653
35 Acres - Fertigation - Cranberry Bogs	425
27 Acres - Aquaculture/Oyster Beds	6,830
1,938 Square Feet - Floating Constructed Wetlands	775
784 Units - Ecotoilets (UD & Compost)	1,448
1,202 Units - I & A Systems	1,448
668 Units - Enhanced I & A Systems	1,448
TOTAL	**17,488**

A summary of the approach and methodology that was applied using non-traditional technologies follows at the end of this report.

Traditional

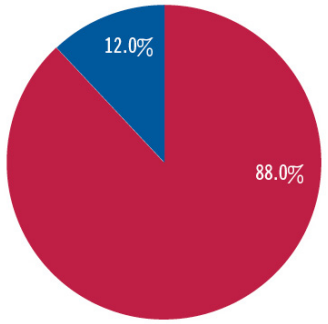
CENTRALIZED TREATMENT WITH DISPOSAL INSIDE THE WATERSHED



Assumes load to be collected and treated is disposed in the watershed, requiring additional collection to offset the load.

The watershed nitrogen threshold cannot be met by collecting 100% of the septic load in the watershed and returning the treated load to the watershed.

CENTRALIZED TREATMENT WITH DISPOSAL OUTSIDE THE WATERSHED



Assumes that the load to be collected and treated is removed from the watershed so no offset is required.

Town of Mashpee Local Progress

The Mashpee Comprehensive Wastewater Management Plan (CWMP) was scoped through a joint Massachusetts Environmental Policy Act (MEPA)/Development of Regional Impact (DRI) review as an Environmental Notification Form (ENF) in 2001. In 2007, the town submitted its Needs Assessment Report entitled, "Town of Mashpee, Popponesset Bay and Waquoit Bay-East Watersheds Needs Assessment Report." Also in 2007, the town completed a technology screening report, which was followed shortly by its draft alternative scenarios and site evaluation report in March 2008.

The Needs Assessment contains a characterization of the nine operating private sewage treatment facilities, including treatment efficiency and excess capacity. This work allowed the town to focus on three potential wastewater scenarios that were developed in 2012. These options were reviewed and served as the basis for development of their preferred alternative. The wastewater scenarios include use of the existing private plants at their planned capacity and either three or four subregional plants with consideration of shared town responsibility. Off-site disposal of effluent outside of the impaired watersheds is an important consideration for the plan's approach. The alternatives analysis included consideration of private effluent disposal sites at New Seabury, Willowbend, and others, in addition to the town's transfer facility site.

The issuance of the final Alternatives Screening Analysis in August 2013 developed the framework of the draft and final plans and identified several alternative approaches to sewering, including shellfish aquaculture and permeable reactive barriers.

In April 2014, the Sewer Commission met with Cape Cod Commission staff to begin the discussion around filing its CWMP. The Recommended Plan includes a significant aquaculture undertaking and an adaptive management approach to achieving water quality goals.

In the fall of 2014, Mashpee adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

In September 2014, the Massachusetts Secretary of Energy and Environmental Affair issued a certificate of adequacy for the Draft Environmental Impact Review (DEIR) for Mashpee's Comprehensive Watershed Nitrogen Management Plan. In the Summer of 2015, the Massachusetts Secretary of Energy and Environmental Affair issued a final certificate Mashpee's Comprehensive Watershed Nitrogen Management Plan. The plan is currently under review by the Commission, although the Commission has already notified the town that phase I of its plan is consistent with the 208 Plan Update.

At the October 2015 Mashpee Town Meeting, the town voted to appropriate $250,000 for shellfish propagation, $32,500 as the first installment on a 3-year monitoring study associated with the shellfish project, funded a full time permanent water quality technician position, $100,000 to reauthorize the Sewer Commission Facilities Study Account and hire a consultant to complete studies and develop a preliminary design for the connection of properties to existing treatment facilities, $80,000 to support the development of inter-municipal agreements with neighboring communities, as well as authorized the use of town-owned land for the purposes of developing wastewater treatment facilities.

In October 2015, the town also approached Barnstable and Sandwich regarding approaches for Popponesset Bay and a potential watershed permit. It is expected that these three towns will collaborate on the first watershed permit in the region in close coordination with the Cape Cod Commission and the Massachusetts Department of Environmental Protection. To accommodate for discussions with Barnstable and Sandwich regarding the watershed permit a DRI extension through the fall has been agreed upon.

In June 2016, Mashpee received $14,600 from the Commission for construction of a floating shellfish seed upweller system to grow quahog seed for initial implementation of their shellfish restoration plan. Funding was part of $142,149 in local grants made by the Commission in support of 208 Plan implementation.

At the Spring 2017 Town Meeting, Mashpee voted to fund monitoring of shellfish aquaculture in Popponesset Bay and Waquoit Bay in the amount of $49,500. Amendments to the Town's nutrient control bylaw were also approved.

Centralized Sewer			1,170	0.157	4,110				
Aquaculture/Oyster Beds						16.32 M	Shellfish	6,830	

Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion. Those scenarios are included in this report.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Management District of Critical Planning Concern (DCPC).

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

Also in 2015, the Town agreed to work with Mashpee and Sandwich on approaches for the Popponesset Bay watershed and a potential development of a watershed permit. It is expected that these three towns will collaborate on the first

Town of Barnstable Watershed Scenario Details

I & A Systems			41	Units	108				
Enhanced I & A Systems			75	Units	108				

watershed permit in the region in close coordination with the Cape Cod Commission and the Massachusetts Department of Environmental Protection.

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Town of Sandwich Local Progress

The Town of Sandwich has an established water quality committee to oversee water quality and wastewater planning efforts. In October 2015 town staff and their consultant (Wright-Pierce) met with Cape Cod Commission staff to discuss watershed planning, decision support tools, and scenario development for Sandwich watersheds. In the same month the town was approached by Mashpee regarding approaches for Popponesset Bay, and a potential watershed permit, and has agreed to participate with Mashpee and Barnstable in this shared effort. It is expected that Barnstable, Mashpee, and Sandwich will collaborate on the first watershed permit in the region in close coordination with the Cape Cod Commission and the Massachusetts Department of Environmental Protection.

Previously the committee developed a scope of work for a Comprehensive Wastewater Management Plan (CWMP) and submitted the scope under the Sagamore Lens Natural Resource Damages Assessment, related to past groundwater contamination at the Textron facility at Joint Base Cape Cod (JBCC). The town received an award of $400,000 t0 conduct its water/wastewater plan and completed a comprehensive needs assessment, as well as an interim wastewater solutions plan to accommodate economic development in the South Sandwich Village Center.

The town spent several years working with a private developer on a development project that included a public-private wastewater component for the construction of a facility that would accommodate the private project, in addition to some public wastewater needs. That project will not be completed, but the town is again seeking a private partner to create new economic growth and to potentially participate in infrastructure development.

The town has participated in discussions at JBCC about the potential use of its existing wastewater infrastructure as a regional option for the Upper Cape towns.

In February 2016 the Town of Sandwich requested a meeting with Commission staff to discuss watershed scenarios and potential modifications to watersheds in which Sandwich has jurisdiction. The town provided collection footprints and assumptions for a single treatment facility to serve all three watersheds (Popponesset Bay, Three Bays, and Waquoit Bay), consistent with the Sandwich CWMP, and identified locations for non-traditional approaches, in addition to credits for stormwater and fertilizer reduction. The Town proposes a 25% fertilizer management credit and a 6.25% stormwater management credit. While the proposed interventions, alone, do not meet the nitrogen allocations identified in Appendix 8C of the 208 Plan Update, the town has expressed a preference to rely on nutrient trading or cost sharing to reduce the load allocated to the downgradient towns in the shared watersheds of Popponesset Bay, Three Bays and Waquoit Bay, where nitrogen reductions can be more cost effectively attained.

Town of Sandwich Watershed Scenario Details

Popponesset Bay	CREDITS		REDUCTION TECHNOLOGIES			REMEDIATION AND RESTORATION TECHNOLOGIES			REMOVAL
NAME OF TECHNOLOGY	% Nitrogen Reduction	Load Reduction (kg-N/yr)	# Properties / Units	Flow Collected (gpd)	Load Reduction (kg-N/yr)	# Units Proposed	Unit Metric	Load Reduction (kg-N/yr)	Total Scenario Load Reduction (kg-N/yr)
Traditional Scenario - Disposal Outside the Watershed									1,820
Centralized Sewer			1,328	230,214	1,820				
Non-Traditional Scenario*									47
Fertilizer Management	25%	32							
Stormwater Mitigation	6.25%	15							

NOTES:

* The Town of Sandwich will rely on nutrient trading as an additional measure to meet the TMDL, if necessary.

Methodology for Selecting Non-Traditional Technology Scenarios

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology were derived from the Technologies Matrix. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

This section summarizes the approach and methodology that was applied during the 208 Update to develop plans for reducing nitrogen loading to estuaries using non-traditional (NT) technologies. It includes descriptions of regional credits for stormwater and fertilizer reductions, regional screening for potential sites for several technologies, and site-specific analyses for others. Nitrogen attenuation rates for each technology are noted below, based on the Technologies Matrix or newer data. The nitrogen thresholds for each embayment were determined from the Massachusetts Estuaries Project (MEP).

Regional credits were developed for potential stormwater retrofits and fertilizer reductions. They were calculated as a percent reduction of existing nitrogen loads as identified in the MEP reports and updated GIS data developed by the Cape Cod Commission.

- **STORMWATER MANAGEMENT:** Most Cape communities have already begun the process of identifying significant untreated stormwater discharges and developing appropriate mitigation projects. With the prospect of the MS4 regulatory requirements it was assumed that additional mitigation efforts would be implemented. Based upon the evidence developed by the University of New Hampshire Stormwater Center that several vegetated stormwater management practices (including bioretention and constructed wetlands) are able to achieve nitrogen reductions of 50% or more and the assumption that only a portion (estimated at 50%) of identified sites would be retrofitted a 25% nitrogen reduction credit was assumed for each watershed. Specific locations and number of locations were not identified; this was deferred to individual towns to consider as part of the suite of nitrogen management strategies.
- **FERTILIZER REDUCTIONS:** Based upon the success of most Cape Cod towns to implement either regulatory or non-regulatory fertilizer management programs and the efforts of the Cape Cod Extension Service in educating homeowners a 25% reduction in fertilizer applications was assumed for each watershed.

Regional GIS screening methods were developed to identify locations for some non-traditional technologies. A GIS viewer was developed as an on-line tool for staff and consultants to utilize during the watershed planning process.

- **CONSTRUCTED WETLANDS/ PHYTOREMEDIATION:** A GIS-based screening method was developed by the Cape Cod Commission to identify and rank parcels of land that have potential for the location of constructed wetlands and phytoremediation. The ranking utilized parcel size and ownership, depth to groundwater, suitable soils, distance from wetlands, and undeveloped parcels. A nitrogen removal rate of 500 kg/Y/acre and 532 kg/Y/acre was used for Constructed Wetlands and Phytoremediation, respectively.
- **PERMEABLE REACTIVE BARRIERS (PRBS):** A GIS-based screening method was developed to identify existing roads that are proximate to receiving waters, downgradient of high density development, run perpendicular to groundwater flow (to have the highest potential to intercept nutrients in groundwater), and where the depth to groundwater is relatively shallow to maximize the area of saturated thickness treated in the aquifer.

Methodology for Selecting Non-Traditional Technology Scenarios

- **FERTIGATION WELLS:** Golf courses were mapped to identify areas where fertigation wells could be utilized to recapture nitrogen-enriched groundwater and re-apply it to the managed turf areas to serve both irrigation and fertilization needs. Most golf courses were assumed to be eighteen holes with a fertilized area of 75 acres. Fertigation water was assumed to have an average concentration of 5 mg/liter. An uptake/attenuation rate of 80% was applied resulting in an assumed nitrogen reduction of 300 kg/year for each golf course with effectively located fertigation wells. In some cases other irrigated areas (such as athletic fields and cemeteries) were identified as potential fertigation locations. A nitrogen removal rate of 4 kg/Y/acre was used.

The MVP tool and other site-specific tools were utilized to quantify nitrogen load reductions for several potential NT interventions.

- **PERMEABLE REACTIVE BARRIERS:** for each PRB that was identified during the prior GIS-screening process an approximate capture area was identified using available water table maps and the wMVP tool. Upgradient contributing areas were digitized within wMVP and the nitrogen load was calculated. A nitrogen reduction of 72.5% was applied (calculated as an average of the reported attenuation range from the Technologies Matrix).
- **CONSTRUCTED WETLANDS (WITH COLLECTION):** Constructed wetlands were considered as a tertiary, polishing treatment for existing wastewater treatment plants. This included small-scale wastewater treatment systems. A nitrogen removal rate of 500 kg/Y/acre was used.
- **AQUACULTURE/OYSTER REEFS:** Potential areas for aquaculture and/or oyster reef restoration were considered based upon discussions with town representatives and review of maps to identify potential areas for these operations without significant conflicts to navigation. In some cases actual recent aquaculture expansions were included where they were developed after the MEP reports were prepared. An assumption of 1 million oysters per acre was used with a nitrogen removal rate of 250 kg/Y/acres.
- **FLOATING CONSTRUCTED WETLANDS:** Potential areas for floating wetlands were considered in areas where no conflicts with navigation or swimming areas were identified. A nitrogen removal rate of 0.4 kg/Y/sq foot was used.
- **INLET WIDENING AND COASTAL HABITAT RESTORATION:** Only considered in areas where these projects were identified by towns or state agencies and where detailed hydrologic investigations and modeling had been performed due to wide variations in nitrate load reduction, flushing impacts, impacts on flooding, and costs (dredging only, replacing infrastructure, removing and replacing roadways or bridges, etc.). Nitrogen removal rates were based on MEP or other studies.
- **INNOVATIVE & ALTERNATIVE SEPTIC SYSTEMS AND ECOTOILETS:** In most cases specific locations for these technologies were not identified. Rather general estimates for the percent adoption were provided based upon discussions with the stakeholder groups and their views on potential adoption rates. In some watersheds a 5% adoption rate was included based upon this stakeholder input. In a limited number of instances specific locations for these technologies were included based upon town input and suggestions. A nitrogen removal rate of 1.658 kg/Y for each system was used for I&A Septic Systems, and 2.984 kg/Y for enhanced I&A systems. A removal rate of 2.542 kg/Y was used for each home installation of an Ecotoilet, and 0.467 kg/Y for installation of urine diversion toilets in public settings.

Finally, the locations of specific technologies were discussed during the 208 stakeholder engagement process. Stakeholders across the Cape 'groundtruthed' potential NT locations and NT scenarios were adjusted accordingly.

Appendix G

CCC Rushy Marsh Watershed Report

WATERSHED REPORT: MID CAPE

Rushy Marsh

BARNSTABLE

WATER THREAT LEVEL

HIGH

Rushy Marsh is an embayment system with shoreline located entirely in the Town of Barnstable. The Rushy Marsh system is disconnected from Nantucket Sound during low tide with tidal waters entering the Marsh intermittently.

The Problem

The Massachusetts Estuaries Project (MEP) technical report (available at www.oceanscience.net/estuaries) indicates that the Rushy Marsh system exceeds its critical nitrogen threshold, resulting in impaired water quality. Although a MEP report is available, a Total Maximum Daily Load (TMDL) for nitrogen has not yet been established.

- **MEP TECHNICAL REPORT STATUS:** Final
- **TMDL STATUS:** TMDL not yet established
- **TOTAL WASTEWATER FLOW:** 1 MGY (million gal per year)
  - Treated Wastewater Flow: 0 MGY
  - Septic Flow: 1 MGY
- **UNATTENUATED TOTAL NITROGEN LOAD (MEP):** 163 Kg/Y (kilograms per year)
- **ATTENUATED TOTAL NITROGEN LOAD (MEP):** 163 Kg/Y
- **SOURCES OF CONTROLLABLE NITROGEN (MEP):**
  - 89% Septic Systems
  - 4% Lawn Fertilizer
  - 7% Stormwater From Impervious Surfaces

CONTRIBUTING TOWN

Percent contributions listed below are the aggregate sub-embayment contributions identified in Appendix 8C of the Cape Cod Section 208 Plan Update (contributions are based on attenuated load where available). See Appendix 8C for detailed town allocations by sub-embayment.

- **BARNSTABLE:** 100%

THE MEP RESTORATION SCENARIO

- **WATERSHED TOTAL NITROGEN REDUCTION TARGET:** 79%
- **WATERSHED SEPTIC REDUCTION TARGET:** 100% (The scenario represents the aggregated sub-embayment percent removal targets from the MEP technical report)

RUSHY MARSH ESTUARY

- **EMBAYMENT AREA:** 15 acres
- **EMBAYMENT VOLUME:** 3 million cubic feet
- **2014 INTEGRATED LIST STATUS:** Category 3
  - Category 3: No uses assessed
  - www.mass.gov/eea/docs/dep/water/resources/07v5/14list2.pdf

RUSHY MARSH WATERSHED

- **ACRES:** 57
- **PARCELS:** 18
- **% DEVELOPED RESIDENTIAL PARCELS:** 33%

DRAFT

- **PARCEL DENSITY:** 3 acres per parcel (approx.)
- **WASTEWATER TREATMENT FACILITIES:** 0

Freshwater Sources

PONDS

- **IDENTIFIED SURFACE WATERS:** 1
- **NUMBER OF NAMED FRESHWATER PONDS:** 0
- **PONDS WITH PRELIMINARY TROPHIC CHARACTERIZATION:** 0
- **2014 INTEGRATED LIST STATUS:** None listed

Barnstable has participated in the Pond and Lake Stewardship (PALS) program that has helped establish baseline water quality. Trophic characterizations are based on most recent Commission staff assessment. The pond in this watershed does not have water quality data that allows a preliminary trophic characterization.

STREAMS

- **SIGNIFICANT FRESHWATER STREAM OUTLETS:** 0

Nitrate concentrations higher than 0.05 mg/L background concentrations, evident in public supply wells located in pristine areas, provide evidence of the impact of non-point source pollution on the aquifer and receiving coastal water bodies.

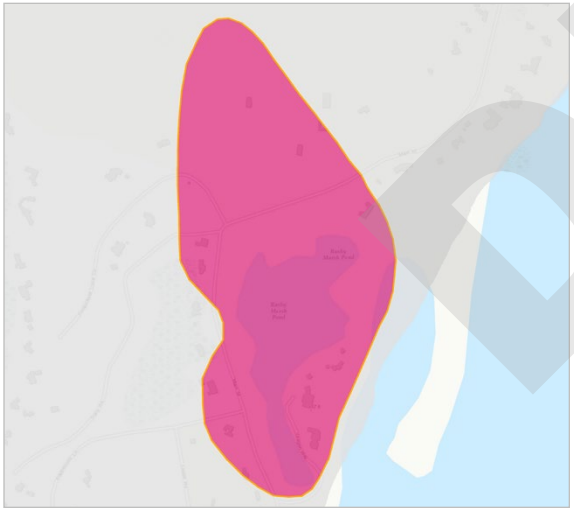
DRINKING WATER SOURCES

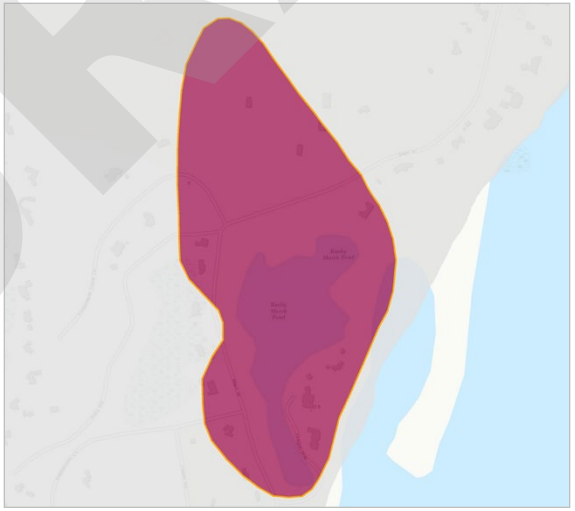
- **WATER DISTRICTS:** 1
  - Centerville-Osterville-Marstons Mills (COMM) Water District
- **GRAVEL PACKED WELLS:** 0
- **SMALL VOLUME WELLS:** 0

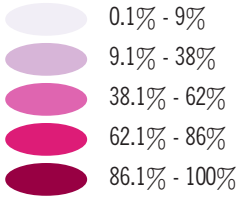
Degree of Impairment and Areas of Need

For the purposes of the Section 208 Plan Update, areas of need are primarily defined by the amount of nitrogen reduction required as defined by the TMDL and/or MEP technical report. The aggregated watershed removal rates for Rushy Marsh are 79% and 100% for total watershed load and septic nitrogen load, respectively (see figures: Subwatersheds with Total Nitrogen Removal Targets and Subwatersheds with Septic Nitrogen Removal Targets).

The nitrogen load from the watershed exceeds the threshold for Rushy Marsh, resulting in impaired water quality. The ecological health of a water body is determined from water quality, extent of eelgrass, assortment of benthic fauna, and dissolved oxygen and ranges from 1-severe degradation, 2-significantly impaired, 3-moderately impaired, 4-healthy habitat conditions.







Subwatersheds with Total Watershed Removal Targets

(Left) Benthic and atmospheric loads directly on embayments are not included.

Subwatersheds with Septic Nitrogen Removal Targets

(Right)

DRAFT

ECOLOGICAL CHARACTERISTICS AND WATER QUALITY

- **OVERALL ECOLOGIC CONDITION:** Severely Degraded
- **MAIN BASIN:** Severely Degraded
- **CHANNEL:** Severely Degraded
- **SENTINEL STATION:**
  - Total Nitrogen Concentration Threshold: 0.99 mg/L
  - Total Nitrogen Concentration Existing: 1.11 mg/L (As reported at the MEP sentinel water-quality monitoring station)

DRAFT

Collection & Non-Collection Scenarios

Regional Data

In 2010, the Commission sought to collect regionally consistent data for the purposes of watershed scenario development. Both parcel data and water use data was identified and collected for the entire region. While the scientific basis for planning is the thresholds identified in the MEP technical reports, each report uses data from different years, and in some cases the MEP data used is 10 or more years old. In addition, there are watersheds on Cape Cod without the benefit of an MEP report; therefore, similar data was not available for planning purposes.

The updated regional data set was used to estimate wastewater, stormwater and fertilizer loads, using the same methodologies as the MEP. This approach allows for a reevaluation of existing development, which may have changed in the last 10 years. Parcel data included in the regional database is from 2010-2012 and water use data is from 2008-2011, depending on the water district. This approach allows for regionally consistent watershed scenario development.

Watershed Scenarios

The watershed scenarios that follow outline possibilities for the watershed. A series of non-traditional technologies that might be applicable are included, as well as the amount of flow and approximate number of residential parcels that would need to be collected if a traditional collection system and treatment facility was implemented. Some assumptions were made in determining the approximate flows and parcels for collection, including a treatment factor of 5 parts per million (ppm), disposal occurring inside the watershed, and no natural attenuation, therefore prioritizing parcels with a direct impact on the water body. Site specific determinations of collection areas may result in the need to collect more or less parcels to meet the nutrient reduction target. The scenarios presented are meant to act as a starting point for discussions regarding effective and cost efficient solutions.

RUSHY MARSH NITROGEN SOURCES	TOTAL NITROGEN LOAD (kg-N/yr)
Wastewater	63
Fertilizer	3
Stormwater	12
Other	4
TOTAL	82
Total Watershed Load (including atmospheric)	82
Total Watershed Threshold	34
TOTAL LOAD TO BE REMOVED	48

DRAFT

Collection & Non-Collection Scenarios

Non-Collection

Collection

DEVELOPED RESIDENTIAL PARCELS IN WATERSHED

1

6 Residential Parcels in the watershed

RESIDENTIAL EQUIVALENTS NECESSARY TO MEET NITROGEN REDUCTION TARGET VIA COLLECTION

1

11 Residential Equivalents Necessary to Meet Nitrogen Reduction Target

= 50 Residential Parcels

11	1,635
Residential Equivalents Necessary to Meet Nitrogen Reduction Target	Flow Collected (gpd)

SCENARIO ASSUMPTIONS: Assumes treatment to 5 parts per million (ppm) nitrogen. Assumes disposal occurs inside the watershed. In this watershed, reduction targets may not be met with disposal inside the watershed. Assumes no natural attenuation; therefore, prioritizing parcels with a direct impact on the water body.

DRAFT

Town of Barnstable Local Progress

The Cape Cod Commission and the Town of Barnstable met and discussed the use of WatershedMVP to evaluate targeted watershed approaches for each of the watersheds in which they have jurisdiction. In 2015, the town reformulated its Citizen's Advisory Committee (CAC) for wastewater planning to better address local needs. In addition to local participation, the newly formed committee (the Water Resources Advisory Committee or WRAC) includes state and regional representatives. Town staff provided modifications to Commission-developed watershed scenarios and presented those scenarios to their WRAC for review and discussion. Those scenarios are included in this report.

The Town of Barnstable operates the Hyannis Water Pollution Control Facility (WPCF), located off Bearses Way in Hyannis, which is the primary wastewater treatment facility serving approximately 2,900 properties in Hyannis and Barnstable village. The treatment facility has been upgraded and permitted to treat additional flows up to a total of 4.2 million gallons per day (MGD), upon meeting requirements of an adaptive management plan approved by the Commission in 2007. Property along Route 132 was acquired by the town in 2002 to potentially accommodate future disposal needs. The site is approved under a 2006 Massachusetts Environmental Policy Act (MEPA) certificate to discharge up to 0.5 MGD. The site is not presently in use. However, a force main and sewer has been extended to the site from the WPCF.

The WPCF treats an average daily flow of 1.46 MGD and a maximum monthly average flow of 1.94 MGD. Treatment performance has averaged 5 milligrams per liter (mg/L) total nitrogen in the treated effluent and the facility has a discharge limit of 5 mg/L under the 2007 Development of Regional Impact (DRI) decision and a limit of 10 mg/L under a Groundwater Discharge Permit (GWDP). The facility is also equipped with sludge thickening, storage and dewatering facilities sized for the current process conditions.

The Town of Barnstable also operates two smaller facilities – the Marstons Mills Wastewater Treatment Facility (WWTF) and the Red Lily Pond Cluster System. The Marstons Mills WWTF is limited to a discharge flow of 42,900 gallons per day (GPD) and is intended to service the Barnstable United Elementary School and the Village at Marstons Mills affordable housing development. The Red Lily Pond Cluster System currently serves 17 homes. According to the comprehensive wastewater management plan (CWMP) approved in 2007, no performance sampling of the system occurs and the system is assumed to produce comparable effluent to any conventional single family septic system.

In addition to municipally-owned facilities, there are two privately-owned treatment facilities treating wastewater from the Cotuit Landing shopping plaza and the Cape Regency nursing and rehabilitation facility. These facilities provide high levels of wastewater treatment. The treatment facility at Cotuit Landing was designed with additional treatment capacity beyond the expected needs of the shopping plaza for potential treatment of flows from neighboring properties.

Barnstable is working on a town-wide nutrient management plan that will provide the basis of its CWMP. The plan will address nitrogen and other needs in watersheds draining to Three Bays, Centerville River, and Lewis Bay. A nitrogen total maximum daily load (TMDL) for Barnstable Harbor has not been approved by US EPA. The MEPA certificate scope for the Final Environmental Impact Report (FEIR) includes engagement in a targeted watershed approach, consistent with the 208 Plan Update.

In the fall of 2014, Barnstable adopted local nitrogen-oriented fertilizer management regulations consistent with the Cape-wide Fertilizer Managem ent District of Critical Planning Concern (DCPC).

In 2015, the Town submitted a Statement of Interest to the US EPA for a hydrogeologic site characterization as an initial step toward piloting a permeable reactive barrier in the town. One of three sites proposed by the Town was selected for characterization. The work was completed in 2016. The draft report is presently being reviewed by the Town.

In June 2016, Barnstable received $28,850 from the Commission to fund upgrades to three stormwater treatment BMPs. Funding was part of $142,149 in local grants made available to communities by the Commission in support of 208 Plan implementation.

Project No. 9019010

EXECUTIVE SUMMARY

The Town of Barnstable, through its consultant, Stearns & Wheler, conducted a pilot test to evaluate the feasibility of injecting treated wastewater into the subsurface using an injection well. This document provides a description of the technology, describes the pilot test operation, and presents results and conclusions to be considered as part of further evaluation of the technology.

The Town is in the process of completing a Wastewater Facilities Plan for their municipal Water Pollution Control Facility (WPCF). One issue facing Barnstable is finding a means to dispose of the treated effluent without creating significant adverse impacts on groundwater levels. In the course of completing the Wastewater Facilities Plan, Stearns & Wheler identified a number of alternatives for discharging effluent in a manner that would not adversely impact groundwater levels. The study concluded that the use of injection wells might be an appropriate method to meet the Town's goals for wastewater management. Subsurface injection may be a beneficial alternative to traditional effluent disposal methods due to smaller land requirements and an increased number of siting options. Injection wells do not have significant visual or public perception impact and may be less expensive. The viability of the technology was evaluated with an injection well pilot test.

Two areas of evaluation were identified for the pilot test. The first area of evaluation related to system operations. An objective of the pilot test was to evaluate operational aspects of the technology, including well design considerations, flow rates, injection pressure, and well plugging and its causes. The second area of evaluation related to environmental impacts of the application of the technology, including the impacts on the water table elevation (i.e., mounding) that would occur as a result of wastewater injection. Additionally, the study was designed to evaluate the fate and transport of nutrients and other wastewater constituents.

Prior to designing and conducting the pilot test, a review was completed of existing injection well projects. Wastewater injection facilities in California and Florida were studied, as well as potable water storage injection projects located in a number of regions of the country. To gain information regarding injection in this region, a groundwater treatment and reinjection program at the Massachusetts Military Reservation was studied. Through the review of these projects, a number of design criteria were identified. The greatest challenge in operating an injection well was determined to be plugging (reducing the injection rate). Plugging may result from bacterial

buildup, injection of suspended solids, injection of entrained air, or chemical reactions that cause precipitation of minerals in the injection zone.

A second challenge in introducing injection wells as an alternative technology is related to regulatory concerns. There was resistance by regulators regarding implementation of a new technology while remaining consistent with existing policies and regulations. An example of this relates to the disinfection of treated effluent. Through our case study review of existing effluent discharge facilities, it was identified that fouling due to biological buildup was probable without disinfection. The pilot test using treated effluent from the Hyannis WPCF demonstrated this to be true. However, because of concerns with the fate of chlorine and potential disinfection by-products, the Massachusetts Department of Environmental Protection (MADEP) would not allow the injected effluent to be disinfected with chlorine.

Based on information gathered from the case studies, on the goals of the pilot test, and the local site conditions, the pilot test was designed with the following specifications:

- Flow Rate - 350 gallons per minute (gpm). High enough to create measurable hydraulic and transport impacts for evaluation.

- Well Location - WPCF. A remote site was considered but not used because of the impacts to the project cost, schedule, and the ability to permit the project

- Disinfection - UV Radiation. The injected waste stream was disinfected using a UV system as required by MADEP, resulting from concerns about impacts of chlorination on groundwater quality (December 14, 1998 meeting minutes). The Town and Stearns & Wheler viewed disinfection with chlorine as a major factor in the success of the project.

- Filtration - Bag System. This was another limiting factor in the success of the test.

The pilot test was conducted in two phases. Phase I, using treated effluent, ended in 11 days as a result of well plugging of the injection zone. Phase II, using potable water, was sustained for approximately three months. The immediate plugging during Phase I was attributed to the build-up of bacteria at the formation face of the injection zone. This was determined after redevelopment failed to restore the well, but treatment with high concentrations of chlorine did

eliminate the plugging. Once the well was restored, approximately 7 million gallons of potable water were injected during Phase II.

Because of the many operational issues encountered during the test, the objectives of further investigation were modified by Stearns & Wheler, with approval from the Town of Barnstable Project Manager, to focus more on operational factors than environmental impacts. A number of conclusions were drawn from the results of the pilot test that should be used in considering the future testing of this technology:

- Injection wells can be a viable means of reclaiming treated wastewater by recharging utilized aquifers (as has been demonstrated in other regions of the United States through the case study review).

- Chlorine disinfection is necessary to maintain a residual disinfectant concentration in the subsurface, which will prohibit the growth of bacteria at the formation face of the injection zone and subsequently result in plugging.

- High level filtration (less than 10 microns) is required to minimize the impacts of injecting suspended solids.

- Injection pressure must be kept at a minimum so as not to disrupt the structure of the injection zone.

- Well design can be improved to increase and maintain efficiency.

- Additional pilot testing related to filtration and disinfection is needed to demonstrate viability before full-scale implementation is considered

Injection wells are used, primarily in Florida and California, for the disposal or reclamation of millions of gallons of treated wastewater each day, demonstrating the viability of the technology. This pilot test demonstrated that filtration and disinfection must be enhanced to levels greater than those used during the pilot test before it can be considered as a viable alterative for the Town of Barnstable. The recent thrust by regulatory agencies toward multiple centralized wastewater systems on Cape Cod, and the need to preserve the Cape's single source aquifer, will only intensify the need to develop sound, practical, environmentally sensitive, and economical

solutions to wastewater treatment and disposal needs. As more centralized systems are built or expanded, there will be a huge demand for valuable land for the purpose of discharging the treated water to groundwater. Injection wells present an ideal alternative that is less land intensive, has less environmental impact, and is more aesthetically acceptable than traditional effluent discharge practices. However, before the required additional pilot testing of this technology can be performed, resolution on MADEP's policy on prohibiting the chlorination of the treated effluent must be reached.

Chapter 1
Introduction

CHAPTER 1

INTRODUCTION

1.1 BACKGROUND

The Town of Barnstable, Massachusetts is in the process of completing a Wastewater Facilities Plan for their municipal Water Pollution Control Facility (WPCF). One issue facing the Town is disposing of the treated effluent from the WPCF without increasing the elevation of groundwater, which could subsequently flood basements and septic systems or cause surface flooding. Historically, ponding has occurred at the existing treatment facility, and groundwater levels have risen to potentially impact low lying areas in the immediate vicinity of the WPCF. The relative contribution of the natural rise in groundwater elevation and any increases in groundwater elevation by the plant have never been clearly determined. Groundwater modeling completed by the Town indicates that effluent discharge from the plant can theoretically result in mounding of the water table. The concern over adverse impacts related to local groundwater mounding in the vicinity of the WPCF is amplified by Town projections that wastewater quantities will increase from the current 2 million gallons per day (mgd) to 4 mgd as planned system improvements are constructed. Alternative technologies to traditional effluent discharge practices must be evaluated for a number of reasons, including:

- the need to reclaim treated wastewater at locations remote from the treatment plant
- the desire for reclamation with minimal impact on groundwater quality and elevation
- the desire for a cost-effective, easy to operate system
- the desire for minimal aesthetic impact and land use
- flexibility in siting discharge sites versus treatment plants
- offering economical discharge point distribution
- the ability to provide an odorless, closed system

While developing the Wastewater Facilities Plan, Stearns & Wheler identified a number of alternatives for discharging effluent in a manner that would not adversely impact groundwater levels. After evaluating the advantages and disadvantages of each alternative, the Town, together with Stearns & Wheler, determined that using injection wells had the potential to meet the Town's goals and objectives for managing treated effluent.

This document serves as a summary of a wastewater injection well pilot test conducted at the Hyannis WPCF for the Town of Barnstable. The purpose of the pilot test was to evaluate the viability of using injection wells as a means of recharging aquifers with reclaimed, treated municipal wastewater. Subsurface injection could be a beneficial alternative to traditional effluent disposal practices since smaller land requirements would allow a greater number of siting options while minimizing visual and public perception impacts. In addition, due to the rising cost of real estate, injection wells could be a less costly alternative to infiltration beds.

1.2 PROJECT SCOPE OF WORK

The pilot test was performed in accordance with Addendum No. 4 to the January 27, 1993 Agreement between the Town of Barnstable and Stearns & Wheler for the development of the Wastewater Facilities Plan. Amendment No. 4 authorized the following tasks. Because the scope of the project was revised as the project proceeded, the execution of each of the tasks is described.

A. **Task 1: Assist Town with SRF Funding.** Following project authorization, but prior to beginning the project, the Town decided to complete all SRF funding application tasks and requested no assistance from Stearns & Wheler. The funds for this task were moved to Task 5, Pilot Test Operation, when it became evident that additional funding would be needed when the testing was extended.

B. **Task 2: Characterization of Potential Injection Sites and Pilot Test Site.** This task had two components: (1) testing two remote discharge sites identified by the Town for use as potential future effluent discharge sites; and (2) completing a preliminary subsurface evaluation of the pilot test site. The first component was not completed; the Town elected not to investigate any candidate remote sites until the pilot test was completed. The characterization of the pilot test site was completed through the installation of a test boring and completion of sieve analysis on the soils recovered from the test boring.

C. **Task 3: Pilot Test Design.** This task was completed as scoped. A design was completed that specified the equipment and layout, including piping and pumps, flow and pressure metering, disinfection equipment, power supplies and controls, the injection well and observation well designs, and locations.

D. **Task 4: Equipment and Well Installation.** This task was completed as scoped. All equipment and wells were installed in accordance with the project design.

E. **Task 5: Pilot Test Operation.** This task was executed very differently than originally proposed. The original plan was to run the well continuously for six months. The well plugged after 11 days of operation. After reviewing potential causes, the well was serviced twice; the first servicing was not effective in restoring the well, and the second servicing restored the well. Prior to restarting the test, Stearns & Wheler recommended, and the Town agreed, continuing the test using potable water. The injection test resumed and was continued for three months. The longer duration of the test, two well servicing events, additional evaluations, and the installation of an additional observation well added to the scope and costs of this task.

F. **Task 6: Water Quality Testing.** Following project authorization, but prior to beginning the project, the Town decided to complete groundwater quality laboratory testing internally. The funding for this task was set aside and later allocated to Task 5 in accordance with Town direction. Because the focus of the project changed from potential environmental impacts to operational issues, the sampling and analysis program was not conducted.

G. **Task 7: Groundwater Modeling.** This task was originally proposed to model the mounding impacts of the injected effluent. Because the focus of the project changed from potential environmental impacts to operational issues, the modeling was not conducted. The funding for this task was set aside and later allocated to Task 5 in accordance with Town direction.

H. **Task 8: Final Report.** This report is being prepared in fulfillment of this task.

1.3 PROJECT GOALS

The ultimate goal of the pilot test was to evaluate the technical and environmental viability of the technology for application in Barnstable. The pilot test was designed to evaluate operational aspects of using injection well technology and the potential for environmental impacts. Specifically, the goals relating to operational aspects included:

- determining optimal flow rate
- evaluating injection pressure and its likely build-up over time

- determining the level of treatment needed to effectively operate the well
- evaluating plugging mechanisms that would limit the efficiency of the well

Goals related to environmental impacts included:

- determining degree of water table mounding caused by injection
- determining fate and migration of nutrients and other wastewater components in the receiving aquifer.

1.4 TECHNOLOGY SUMMARY

Prior to proceeding with design and execution of the injection well pilot test, a review of the existing application of the technology was completed. The purpose of the technology review was to determine how injection wells are being used, in what geologic environments injection is occurring, and to identify design considerations to be used in the pilot test. Other design considerations were site specific and would need to be based on existing operations. The technology review summary is included as Appendix A.

Chapter 2

Pilot Test Design and Construction

CHAPTER 2

PILOT TEST DESIGN AND CONSTRUCTION

2.1 PILOT TEST DESIGN CRITERIA

The issues identified in the technology review (Appendix A) provided a significant amount of information during the development of the basis of design for the pilot test. The pilot test was designed to evaluate:

- the operational and mechanical aspects of operating an injection well (in particular, evaluating plugging due to precipitation of solids and development of biofilms [biofouling])
- the hydraulic impacts of injection of wastewater
- concerns related to nutrient and bacteriological transport and exposure

The goal of the pilot test was to determine whether injection is a practical alternative for reclaiming wastewater, achieved by studying the following issues to make that judgment:

- Determine the nature of water table mounding associated with shallow well injection. What would the maximum water table elevation increase be at the well, and what would be the radial extent of the cone of influence? What would be the potential impacts to zones of contribution of production wells and to surface water bodies?

- Determine the extent to which bacteria, nutrients, and other wastewater constituents would be transported toward potential receptors, such as surface water or production wells.

- Evaluate biological and chemical activity at the well screen and in the injection formation that could affect the injection efficiency of the well.

- Determine the nature of the clogging, if any, so that remedial treatments can be included in final design.

- Gain information from the pilot test to develop design criteria for full-scale systems.

2.2 BASIS OF DESIGN

The basis of design for the pilot test was developed based on the goals of the test and operational and environmental considerations following a review of other injection well projects; meetings (telecons) with Massachusetts Department of Environmental Protection (MADEP) representatives; and input from Mr. Peter Doyle, Supervisor of the Barnstable Water Pollution Control Division, and other Town of Barnstable representatives. The basis of design for the pilot test is as follows:

A. **Flow Rate.** It was determined that a flow rate of 0.5 mgd, or 350 gpm, would be the target operational flow rate. The flow rate for the test had to be high enough to result in significant measurable effects to the water table. The effects had to be sufficient enough to make evaluations of mounding and the resultant groundwater flow rates and directions. However, the flow rate did have to be limited. The primary limiting factor was cost. As flow rate increased, so would the costs of the wells, pumps, piping, and treatment systems. It was determined that a pilot test facility capable of conveying 0.5 mgd could be constructed for $250,000, a cost determined to be manageable by the Town.

B. **Well Location.** It was determined that the pilot test well would be located in the southeast area of the Hyannis WPCF property. This location was selected primarily as a function of cost and schedule. A remote site location was considered first and was suggested by MADEP. A remote site would have been advantageous because impacts of recharge of the balance of the wastewater at the treatment plant's infiltration beds would be minimized, allowing a better assessment of the impacts of the well. However, costs and time associated with identifying a remote site, gaining access to the remote site, permitting a remote site facility and constructing a pipeline up to 2 miles long would have significantly impacted the schedule and cost of the project. The location near the existing plant facilities was selected because minimal piping and pumping would be required and power was readily available, and also because the balance of effluent flow could be diverted to the sand infiltration beds located on the opposite end of the property (far north end of the site and/or far west end of the site).

C. **Disinfection Requirements.** Based on past case studies (Florida and California; see Appendix A), Stearns & Wheler determined that the effluent liquid stream should be disinfected

prior to injection for the dual purpose of minimizing potential bacteriological transport into production well Zones of Contribution, as well as minimizing the potential for the development of biofilms causing plugging (biofouling) of the well. The MADEP was concerned that concentrations of heavy doses of chlorine (greater than 3 mg/L), the most common disinfectant, might be detrimental to the quality of groundwater; therefore, UV disinfection was specified for the effluent.

MADEP has repeatedly stated that it is their policy to encourage disinfection through UV systems. This policy is not written. Concerns related to disinfection were verbally expressed by MADEP representatives at a December 14, 1998 meeting, which was held to gain regulatory endorsement and define MADEP requirements for the project. At this meeting, Stearns & Wheler presented findings that indicated filtration and disinfection were routine treatment practices for wastewater effluent injected into groundwater. It was identified that the lack of chlorination residual added greater risk to the success of the project. The project proceeded using UV disinfection. The MADEP is currently reviewing its policy on chlorination of injected wastewater effluent into the groundwater.

D. **Filtering Requirements.** As indicated, injection wells are susceptible to plugging due to fine solids as well as biofouling. Filtering is a standard treatment practice for injection wells to remove fine particles. At the meeting with MADEP, it was determined that UV disinfection would be required but that filtration could be eliminated in the interest of keeping the project within the original budget. However, in the course of finalizing the design, Stearns & Wheler recommended that the test be modified to include a filtration device that would help sustain a constant injection rate. Because of the high cost of the sand filter that would be required to treat the pilot test flow of 350 gpm, and because of the presumably high level of quality of the wastewater regarding suspended solids (4 to 8 ppm TSS), it was determined that filtering could be accomplished using a bag filter system. The mesh size of the filters would be adjusted for optimal performance during the test. The filter selection and design was presented to the Town at a progress meeting held on October 14, 1999 and approved.

E. **General Well Construction.** The injection well was sized to be 10 inches in diameter. The well casing diameter is primarily a function of the diameter of the screen, which needs to have enough open space to convey 350 gpm to the aquifer with minimal headloss. The well would be completed in the uppermost aquifer, since a goal of the full-scale system is to replenish the water source aquifer. Discussions were held between the Town and Stearns & Wheler

regarding the possibility of completing the well above the saturated zone. Stated benefits included less injection pressure, filtering achieved by the naturally dry sands, and the potential for the well to rehabilitate itself of biological fouling if it is shut off and returns to a dry state. Because of the importance of being able to develop and redevelop the well if it became plugged, Stearns & Wheler and the Town agreed that the well would be completed below the water table.

F. **Monitoring Program.** The original monitoring program had three components:

1. **Operational Monitoring**. Injection flow rate and pressure (water level in injection well).

2. **Hydraulic Monitoring**. Monitoring mounding by periodically checking water levels in area wells.

3. **Water Quality Monitoring**. Groundwater quality, as determined by sampling area wells, was originally proposed. Six new monitoring wells were installed on the treatment plant property, and 10 of the existing wells on and near the treatment plant property were selected for the sampling program. Monitoring well locations are shown on Figure 1. Wells were to be sampled monthly for BOD, TSS, TS, nitrate, fecal coliform, DO, ammonia nitrogen, total phosphorus, and soluble reactive phosphorus.

As the pilot test proceeded, the performance of the well necessitated that the emphasis of the test be changed from evaluating environmental impacts to evaluating operational aspects of the well. As a result, the monitoring program was modified. Because the large quantities of water originally anticipated were not injected, the water quality monitoring program was eliminated. Also, the hydraulic (mounding) monitoring program was modified. Water levels were only recorded in the three monitoring wells closest to the injection well (Wells 2-SW, 10-SW, and 100-SW). Operational monitoring (injection rate and water level in the injection well) was continued as designed.

2.3 PILOT TEST FACILITIES CONSTRUCTION

A. **Pilot Boring and Observation Well Installation.** Prior to construction of the pilot test facilities, a pilot boring for the injection well was installed and completed as an observation well, and five additional observation wells were installed. The pilot boring was installed to a depth of

67 feet. The entire section penetrated down to 60 feet was comprised of medium to coarse sand. At 60 feet, the sand became finer. A number of samples were collected for the purpose of conducting sieve analyses to determine the most appropriate interval for setting the well screen and determining the slot size for the well screen. An monitoring well, designated as PT-10SW, was installed in the pilot boring. The observation well was completed with a 10-foot screen in the interval from 39 to 49 feet.

Upon completion of the pilot boring, and Well PT-10SW, the five additional observation wells described above were installed on the WPCF property to supplement existing monitoring wells.

B. **Well Installation and Development.** The injection well was installed from October 26 to October 28, 1999 by D.L. Maher Co. Maher was contracted to provide these services because of their experience in designing and installing injection wells related to remediation activities at the MMR. Maher assisted in the well design based on our specifications; in particular, the desired flow rate. The screen slot size was also specified by Maher based on sieve analysis of sand samples from the proximal observation well, Well PT-10SW, located 10 feet away.

A diagram of the well, as constructed, is shown in Figure 2. The well is 59 feet deep. It was installed by advancing a 16-inch boring and installing a 16-inch steel casing. The 10-inch well was then installed into the 16-inch steel casing. The 10-inch injection well was constructed of 10-inch Schedule 40 PVC pipe with a 10-inch diameter, 0.100-slot stainless steel screen. The well screen was set from 36 to 58 feet, providing 22 feet of screened interval. The annular space was filled with #4 sand to a depth of 28 feet. The temporary 16-inch steel casing was removed from the boring as the well completion material was placed. A 2-foot thick bentonite pellet seal was emplaced, and the remainder of the annulus was filled with cement-bentonite grout.

The well was completed with a 4-inch Schedule 40 PVC injection tubing that extended from the surface to a depth of 37 feet. A 15-foot 4-inch diffuser pipe was attached to the bottom of the injection tubing. The purpose of the diffuser was to evenly spread the discharge across the entire length of the screen. Just above the diffuser pipe, a pressure control valve was installed which required a certain amount of pressure (water column) above it to open. This was done to provide a constant column of water in the injection tubing, which was important to prevent water from cascading into the well. Cascading allows air to be entrained into the injected water, which in turn could lead to plugging of the injection zone. The injection tubing was held in place by three sets of centralizers. A 1-inch HDPE tube extended from the flange at the top of the well to a

depth of 44 feet to allow water level measuring instruments to be lowered into the well. With the exception of the access tube, the well is pressure tight. With the access tube plugged, the well was designed to operate under a positive pressure that would allow injection at greater flow rates. It was anticipated that the well would operate under gravity flow until plugging conditions developed.

The well was developed by pumping and surging from November 1 to November 9, 1999. At first, the well was pumped at a rate of 15 gpm. The development pump was positioned at increased depths in the screen as development continued. In addition to pumping, the well was periodically surged by moving the pump up and down within the well while the pump was off. Pumping rate increased to 125 gpm, to 200 gpm, to 214 gpm. An additional pump was installed on the discharge line to increase pumping capacity and on the last day of development, the pumping rate increased to 349 gpm. When pumping at 349 gpm, the water level in the well was drawn down from 26.2 feet below grade to 32.3 feet below grade, a total of 5.1 feet.

C. **Surface Equipment and Controls**. The surface facilities for the pilot test had the following components. A submersible pump was mounted in one of the plant's two chlorine contact tanks. The wastewater treatment facility controls allowed the effluent stream at the plant to be split to either one or both of the facility's two chlorine contact tanks. For the purpose of the pilot test, approximately 0.5 mgd was diverted to Chlorine Contact Tank 2. The balance of the plant flow was discharged to Chlorine Contact Tank 1 for chlorination and discharge to the plant sand beds.

The pump speed was controlled using a variable frequency drive (VFD). The VFD received a flow rate signal at the injection well. As flow rate declined at the well as a result of filter or well plugging, the VFD would increase the pump rate to sustain a constant and preset injection rate.

A four-chamber bag filter system was located at the well. The multiple chambers allowed flow to continue uninterrupted as the bags were changed. Both 10-micron and 25-micron bags were available for the test. A flow meter with a flow volume totalizer and a chart recorder was between the filters and the wellhead.

A schematic of the system is shown on Figure 3.

Chapter 3

Pilot Test Operation

CHAPTER 3

PILOT TEST OPERATION

3.1 PHASE I

The pilot test was designed to operate continuously for a six-month period. However, within two weeks of startup, the well rapidly plugged. As a result, the test was conducted in two phases: Phase I, which lasted for 11 days, was followed by well servicing; and Phase II, which lasted for approximately 3 months.

A. **Operation.** The injection well pilot test was initiated on February 15, 2000 at the design rate of 350 gpm with filtration accomplished through 10 micron (μ) bag filters. Within two hours, as a result of the filters becoming plugged, flow slowed considerably from 350 to 90 gpm. The 10μ filters were replaced with 25μ filters in an effort to increase the running time between filter changes. The well generally operated consistently through the first several days of the test. On the first day, the water level in the well increased from 30 feet below grade to 18 feet below grade, indicating either mounding or a loss of injection pressure across the screen or formation face. After four days, the water level in the well rose to the top flange and the well began to operate under positive pressure. Injection rate could only be sustained in the 100 to 125 gpm range. After water began seeping from the top of the well through the water level observation tube, it was shut off twice to let water levels recover. Both times, the well pressurized immediately upon being restarted, and sand surrounding the well at the surface began to cave in, with the resultant hole (2 to 3 feet across, 1 to 2 feet deep) filling with water.

It was not clear initially whether the increase in water level in the well was a result of hydraulic loading (mounding) or a result of plugging. To determine the cause, the well was shut down, the water level was allowed to recover, and the well was restarted at lower flow rates. However, even at lower flow rates, the well no longer accepted water. This indicated that the well had become plugged rather than simply filling up as a result of hydraulic loading.

After 11 days of operation, the injection well was shut down since the well or formation no longer accepted injected water. In that time period, 2.2 million gallons of water had been

injected. The water level within the injection well through the course of the first eleven days is shown on the graph on Figure 4.

B. **Evaluation of Phase I Performance.** It had become evident that the well screen or formation face had become plugged. Based on the literature review, there were four possible plugging mechanisms: (1) biological plugging; (2) plugging by total suspended solids in the water; (3) air entrainment; and (4) chemical precipitation in the injection zone. Each of these plugging mechanisms had been considered prior to startup, and in all likelihood, each was contributing to the plugging of the well to some degree. The goal was to determine which was causing the greatest impact and reduce those impacts. Each plugging mechanism was evaluated as follows:

1. **Biological**. Biological plugging, i.e., the growth of bacteria at the well screen or aquifer face, was considered to be the most likely source of the plugging. Literature reported that this is the most frequent source of plugging whether it be in effluent disposal wells, groundwater treatment system wells, or potable water storage wells. Bacteriological growth is common as oxygenated water is injected into formations where there are indigenous bacteria. In the case of treated effluent, elevated levels of nutrients can also serve to make the bacteria flourish. The most effective means of combating bacteriological growth is through the use of a chemical disinfectant such as chlorine. Due to concerns related to resultant groundwater quality, as expressed in the December 1998 meeting, MADEP would not allow chemical disinfectant to be used, since the effluent was being injected into a potable water supply aquifer. As a result, disinfection was accomplished through the use of a UV disinfection system. Although the UV system did serve to disinfect the effluent, the effluent still carried nutrients and oxygen to the aquifer where natural bacteria could thrive.

Iron-forming bacteria commonly thrive under these conditions; however, a sample of the slime on the screen was collected and tested and found not to be an iron-forming bacteria, but a common slime bacteria (*Klebsiella oxytoca*).

2. **Total Suspended Solids**. Suspended solids entrained in the effluent was a known plugging mechanism. Filtration was included in the system to eliminate as many of the solids as possible; however, the project budget limited filtration to the use of a bag filter system. When plugging first became evident, the TSS concentration in the injected water

was measured and found to be 6 mg/L after passing through 25μ filters. Case studies suggested that a target TSS load should be less than 2 mg/L with filtration down to 10μ. Although the test was started with 10μ filters, flow could only be sustained for a short period of time and larger mesh filters were used. Efforts were made to use 25μ filters, but 75μ and 100μ filters were also used during Phase I to evaluate performance under those conditions. Because the size and concentration of TSS was elevated compared to recommended levels, plugging as a result of TSS loading was considered likely.

3. **Air Entrainment.** The injection well design took into account the fact that entrained air can plug the pore space in sandy aquifers just as solid particles can plug pore space. To minimize the impacts of entrained air, the injection tubing was designed with a pressure control valve at the bottom that would only open with a specific head of water over it. This would result in creating a standing column of water in the injection tubing, minimizing cascading and the entrainment of air into the system. Although the performance of this device could not be verified, it was believed to be functioning as designed, with air entrainment being a minor cause of plugging, at the very least.

4. **Chemical Precipitation.** Chemical precipitation was also a potential cause of plugging. Prior to starting the pilot test, the chemistry of the natural groundwater, the treated effluent, and the aquifer matrix material was evaluated and results were compared. Analytical data is summarized in Table 1. Particular attention was paid to dissolved oxygen (DO), pH, and iron. Concerns lie in the fact that if the effluent contains high levels of DO or has a high pH, dissolved iron in the natural groundwater would come out of solution and precipitate on the well screen or on the formation pore space, plugging the passage of water. A review of the data indicates that the pH, iron content, and DO of the effluent and groundwater were generally consistent, and that no notable chemical reaction should have occurred that would significantly impact the performance of the well. As a result, it was concluded that although some chemical precipitation may be occurring, it is not the most likely cause of plugging.

C. **Well Chlorination/Restoration.** After review of the Phase I results, it was decided to service the well and resume a modified pilot test. The well servicing involved injecting chlorine into the well to treat the plugged screen and formation pore space and to redevelop the well to remove fines that might be plugging the screen or formation. The well servicing proceeded as described below.

When the well was opened, it was discovered that 20 feet of sand had accumulated in the well, virtually plugging off the entire screened interval. When the sand was removed, a TV camera survey was conducted to evaluate the condition of the screen. Because of the amount of sand that was present, it was initially believed the screen must have broken. The TV camera showed that not only was the screen fully intact, but it was clear, indicating that there was little buildup of biological material that would have plugged the screen. After the well was cleaned out, it was treated with a 1,000 ppm chlorine solution.

Following treatment, an attempt was made to redevelop the well. After pumping at 30 gpm for 2 minutes, the well went dry, yielding no more water and indicating that the formation was still plugged. The well was treated a second time with 8,000 gallons of 6,000 ppm chlorine solution. Following the second treatment, redevelopment was attempted again. This time, the well again yielded 350 gpm with 10 feet of drawdown, performance similar to the initial development of the well. The success of the chlorine treatment led to the conclusion that although multiple plugging mechanisms were probably contributing to the well's diminished performance, the biological plugging of the formation face was apparently the most significant factor.

With the well performance regained, a plan for continuing the pilot test was developed.

3.2 PHASE II

A second phase of testing included a step test, injecting potable water at steadily increasing rates. Injecting potable water would allow an assessment of the hydraulic impacts of injection alone, without disruption by water quality factors associated with injecting treated effluent. Following the potable water step test and depending on the results of that test, the pilot test with treated effluent would be resumed, preferably with improved filtration and disinfection implemented. Data gathering was enhanced by the addition of one additional monitoring well, 2 feet away from the injection well. The purpose of this well was to evaluate the change in head between the inside of the well and just outside the gravel pack to determine where the plugging may be occurring. The proximal observation well would provide data to suggest if the plugging was occurring at the formation face or deeper into the formation.

Evaluation of Phase I operations, the well servicing, and the planning for Phase II took place through the summer of 2000. On September 6, the pilot test was resumed. Potable water was obtained by piping water from a fire hydrant into Chlorine Contact Tank 2. The rest of the test

and equipment was used in the same way as Phase I. Filtration of the potable water was continued using 10μ filters throughout the test.

The well was operated for approximately one month at 50 gallons per minute. During that time period, water level in the well and the depth to the bottom of the well were recorded on a daily basis. The depth of well measurements was conducted to determine if there were any accumulations of sand in the well. During the first 30-day period, the depth to water in the well increased steadily from 29 feet below grade to 17 feet below grade. A plot of water levels in the injection well, as well as neighboring monitoring wells, is presented as Figure 5. There was no accumulation of sand in the bottom of the well. The buildup of injection pressure, as indicated by the rise in water level, was attributed to three possible factors:

1. The potable water has some TSS content as indicated by the fact that filters were still being used and accumulating solids out of the potable water supply.

2. The potable water may have had a DO level that would have caused the growth of bacteria, similar to the effluent.

3. For a short period of the test, in order to accommodate the needs of the plant, it was necessary to pipe water directly from the fire hydrant to the filters and well, bypassing the chlorine contact tank and submersible pump. The flow characteristics directly from the hydrant were different than from the submersible pump, presumably more turbulent and aerated. When it was discovered that flow directly from the hydrant may have been adversely impacting the well performance, the test was suspended until the chlorine contact tank could be used again.

When normal pumping could be resumed, the injection rate was increased to 100 gpm on October 9 for a period of 14 days, ending on October 24. During the 100 gpm period, the water level in the well steadily increased from 17 feet below grade to 7 feet below grade.

On October 24, the pumping rate was increased to 150 gpm. Until November 1, the water level in the well increased steadily until it reached the top of the well. At that point, the pumping rate was returned to 100 gpm and was continued at that rate until November 21. During that time period, the water level in the well fluctuated between 1.5 and 7 feet below grade, with water returning to a lower level in the well near the end of the test.

Following a presentation to MADEP on October 31 and subsequent conversations with MADEP on present agency policy prohibiting chlorine treatment of injected effluent, the pilot test was suspended on November 21, 2000. During Phase II, approximately 6.9 million gallons of water were injected.

Chapter 4
Evaluation of Results

CHAPTER 4

EVALUATION OF RESULTS

4.1 SUMMARY

The pilot test was originally designed to inject 350 gpm of effluent for a six-month period with operational and environmental factors being tested. As a result of the performance of the well, the pilot test scope was modified. The test operated for approximately 3-1/2 months, with operational factors being the entire focus of the test. Although the test was not completed as originally planned, a great deal of valuable information regarding the operation of an injection well in Barnstable's hydrogeologic environment was obtained. The results from the pilot test are both conclusive and non-conclusive and suggest additional pilot testing would be needed prior to any full-scale implementation.

4.2 PILOT TEST OBSERVATIONS AND RECOMMENDATIONS

A. Plugging by Biological Fouling (Biofouling).

1. **Observation.** The severe plugging of the injection well and its rehabilitation through high concentration chlorine treatment suggests that biological fouling was the most significant cause of plugging.

2. **Recommendation**. Injected wastewater needs to be disinfected prior to injection. Disinfection using chlorine is a standard practice in the underground storage of potable water (aquifer storage-recovery, or ASR) applications, as well as in wastewater injection facilities in Florida and California. The need for disinfection was recognized during the research and design phase of this project. Because of concerns related to the formation of disinfection by-products (DBPs) and their potential migration into water supplies, MADEP made the determination that chlorination at the levels needed (3 to 5 ppm) would not be acceptable (meeting with MADEP, December 1998). Treated wastewater at the treatment plant that is recharged via sand infiltration beds is treated to 1 ppm.

Prior to the pilot test (meeting with MADEP, December 1998), MADEP indicated that disinfection could be achieved through UV treatment. Although the UV treatment does disinfect the waste stream, the pilot test revealed that simply disinfecting the waste stream was not sufficient. It was learned through the pilot test that a disinfectant residual is needed in the injected waste stream, especially with injection into an aquifer with its own population of natural microbes. Although the injected waste stream itself is disinfected, it is still a nutrient- and oxygen-rich stream that may make the indigenous microbes flourish. With no disinfectant residual, the potential for biofouling increases.

Biofouling was not necessarily unexpected, as plugging through microbial growth is the most common cause of the loss of injectivity in injection wells. Future pilot testing and full-scale installations, if undertaken, will require disinfection through chlorination or a combination of chlorination and UV disinfection. A discussion on the management of disinfection by-products is provided below (paragraph E.1, Regulatory Concerns).

B. **Plugging by Buildup of Solids.**

1. **Observation.** Although the success of the chlorine treatment suggested the limiting factor affecting plugging was the result of microbial growth at the formation face, injection of fine-grained particulates was also a likely contributor. As stated previously in this report, the majority of the test was conducted using 25μ bag filters. This resulted in a solids loading of 6 ppm TSS. This is compared to the target level of 10μ filtration to 2 ppm TSS.

2. **Recommendation.** For future pilot testing and full-scale installations, enhanced filtration will be necessary. Sand or multimedia filters are most typically used in injection well installations. Multiple units are used to accommodate design flow rates and to allow cycling from one unit to another to permit continuous operation. An operational consideration with sand filters is the need to backwash the filters and manage the backwash water. At a wastewater treatment plant, returning the backwash water to the headworks is a reasonable method. Cartridge filters have also been used successfully, although cartridge replacement can be a significant O&M cost. Membrane filtration is the most effective treatment, becoming more frequently utilized as the number of water reclamation and recharge projects increases. Membrane filters can reduce particle size to .2 microns and can even filter out protozoa, bacteria, and some viruses.

C. **Plugging By Air Entrainment.**

1. **Observation.** It is possible that air entrainment contributed to plugging. Severe plugging occurred during Phase I, and to a lesser extent during Phase II of the pilot test. Although it is not possible to determine the degree to which each of the potential plugging mechanisms (biological, solids, chemical precipitation, or air entrainment) contributed to the plugging, each may have contributed to some extent. As stated previously, the well was designed to retain a standing column of water in the injection tubing to minimize cascading. Although it is not certain, it is possible that at the time hydrant water was discharged directly to the well in Phase II, excessive turbulence could have resulted in the entrainment of air.

2. **Recommendation.** Like the pilot test well, future wells must be designed to minimize cascading. Additionally, pumping or conveying wastewater to the well must be done in a manner that minimizes turbulence and aeration. The positive displacement pump used for the majority of the pumping test met that criteria.

D. **Disruption of Aquifer Materials and Injection Pressure.**

1. **Observation.** During Phase I, surface soils around the injection well began to cave in. A depression 2 to 3 feet in diameter and 1 to 2 feet in depth formed at the wellhead and filled with water. Initially, the cause of the depression was not known. When the well was opened for servicing, approximately 20 feet of sand was encountered in the screen. Based on the observations and the well performance, the following conclusions were developed. The formation face became plugged due to the buildup of microbial material. Because the plugging prevented the water from entering the formation, the injected water began circulating between the formation, the gravel pack, and the well screen. This circulation drew fine sand particles smaller than the screen slot size into the well, further reducing the injectivity and causing the collapse of the surface soils. Similar occurrences were identified in literature following the observation of this phenomenon during the pilot test. Based on the findings of prior cases, Demicco (1994) recommended that injection pressure be limited to 1/10 of a foot for every foot of saturated thickness within the aquifer above the well screen.

2. **Recommendations.** The injection pressure must be minimized to reduce the chances of fluidizing and mobilizing the sands in the screened interval of the well. The rule of thumb regarding injection pressure and saturated thickness should be regarded. Greater injection pressures can be used if the screened intervals of the injection well are installed as deep into the aquifer as feasible while meeting the other goals of the project; in this case, reclaiming water for future use. Minimizing turbulent flow and injection pressure at the formation face can also be achieved by maximizing the well diameter, well screen length, and screen slot size, as long as the purpose of the screen to hold out fines is not compromised.

E. Disinfection By-Product Fate and Migration.

1. **Regulatory Concerns.** MADEP has regulatory review and approval over the work that was completed as part of the pilot test operation. The subsurface discharge of treated effluent requires a groundwater discharge permit. The Hyannis WPCF site was chosen for the pilot test because administrative approval of the test could be obtained without filing an application for a new groundwater discharge permit.

As indicated previously, MADEP objected to the use of elevated levels of chlorine and required the use of UV disinfection. The plant presently treats recharged wastewater to approximately 1 ppm residual chlorine. Typical injection projects use a residual concentration of 3 to 5 ppm. Although MADEP does not specifically prohibit chlorination, and there is no regulation prohibiting chlorination, it is MADEP's policy to limit the concentration of chlorine in recharged groundwater due to concerns about the fate of the chlorine and associated DBPs. Using chlorine to treat water with organic content has the potential to form the DBPs haloacetic acids (HAAs) and trihalomethanes (THMs). Because these by-products have been identified as carcinogens, their presence in a potential drinking water source is of concern to the regulators. As of December 16, 2001, USEPA established MCLs of 80 μg/L and 60 μg/L for THMs and HAAs, respectively.

Based on the observations made during the test, the well lost its injection capacity due to excessive biological fouling. At the conclusion of the pilot test, the need for disinfection through chlorination was reported to MADEP.

2. **Response**. In 1993, a study was completed (Singer et al., 1993) that evaluated the fate of these DBPs upon injection into the subsurface. The investigation was conducted to evaluate the quality of drinking water injected into the ground for storage and future recovery for distribution. In this study, it was observed that THM concentrations, initially in the 70 to 90 μg/L range, decreased to nondetect levels within nine days of injection. HAA concentrations, initially in the 40 to 50 μg/L range, decreased to nondetect levels by the 56th day. No residual chlorine was detected in the recovered water after one day.

The study further evaluates the geochemical conditions in the aquifer that contribute to the degradation of the DBPs. Rather than having the disinfection of treated wastewater prohibited due to concerns related to the fate of DBPs in potential water sources, future pilot testing should be conducted which includes chlorination and monitoring for DBPs in groundwater at various distances from the injection well.

F. **Nitrosodimethylamine**.

1. **Regulatory Concerns.** Upon hearing of the pilot test results and recommendations for disinfecting treated wastewater, MADEP evaluated concerns related to the fate of DBPs, including discussions with operators of wastewater injection well facilities. That evaluation revealed newly identified concerns related to another disinfection by-product, nitrosodimethylamine (NDMA).

NDMA has only recently (1998) been identified as a contaminant and there is not yet a MCL or standard. California recently established an action level of 2 ng/L, but increased the action level to 20 ng/L (Bloetscher, 2001). NDMA is not a manufactured chemical in the United States; it is a by-product of some manufacturing processes and has entered the environment as a result of its formation in that manner. NDMA has been detected in raw water at southern California water production facilities. Investigations also found NDMA in chlorinated wastewater and in potable drinking water. Research has concluded that NDMA can form as a result of water or wastewater disinfection. In the case of wastewater, the formation of NDMA appears to be related to the presence of nitrate, nitrites, and ammonia. Detection of elevated levels of NDMA at Water Factory 21 in California, a water reclamation facility using injection, has resulted in the requirement of routine monitoring for NDMA.

2. **Response.** NDMA can be reduced or eliminated at two points in the treatment process. Either the precursors to NDMA formation, the nitrogen compounds, can be significantly reduced through high levels of filtration; or NDMA can be destroyed through UV disinfection. The high levels of treatment could also serve to minimize the formation of THMs and HAAs.

Chapter 5

Conclusions and Recommendation

CHAPTER 5

CONCLUSION

5.1 CONCLUSION

The pilot test demonstrated that injection wells can not be operated for any extended period without high levels of filtration and disinfection using chlorine. To be considered a viable technology for the recharge of treated wastewater, the injection facility would require:

- high levels of filtration, that is filtration to less than 10 microns; and

- disinfection using chlorine that results in a residual concentration of chlorine entering the injection zone to minimize bacteriological growth that causes formation face plugging. Precedent projects indicate an operating range of 3 to 5 parts per million chlorine with periodic treatment with higher concentrations is likely to be needed.

Based on these requirements, the pilot test demonstrated that injection wells can not be considered a viable technology for this site at this time. MADEP does not presently allow chlorination of treated effluent with concentrations of chlorine needed to limit microbial growth to the extent that would make plugging impacts economically manageable.

Injection Well Technology

APPENDIX A

INJECTION WELL TECHNOLOGY

GENERAL SUMMARY

Prior to proceeding with design and execution of the injection well pilot test, a review of the existing application of the technology was completed. The purpose of the technology review was to review how injection wells are being used, in what geologic environments injection is occurring, and which design considerations have to be included in the test based on existing operations.

Subsurface injection of water is generally practiced for a number of reasons, including groundwater control, solution mining, waste disposal, and recovering geothermal energy. Subsurface injection of municipal wastewater is a common practice in Florida and California but the application of this technology has little precedent in the northeast. Industrial hazardous wastes are disposed of using injection wells in the Gulf Coast region and in the Great Lakes area. Oil field brines are disposed of via injection wells in most of the oil-producing regions of the country, including the Gulf Coast region, the mid-Atlantic region, Ohio, and Michigan. These practices are different from the wastewater reinjection that Barnstable is considering because the wastes are disposed of in consolidated rock layers several hundred or several thousand feet deep, into aquifers that have been demonstrated to be geologically isolated from aquifers used for water supply (underground sources of drinking water [USDWs]). Injection in these situations is into groundwater with greater than 10,000 ppm total dissolved solids (TDS) that is not suitable for use as a water supply.

In Florida, municipal wastewater is disposed of via injection wells into consolidated rock. Some disposal occurs in the Floridan Aquifer, which is a potential water supply aquifer; in the Biscayne Aquifer which, remote from injection sites, is a utilized water source; and into the Boulder Zone, a saline aquifer with no use potential. Municipal wastewater injection has been pilot tested on Long Island and utilized for decades in California to mitigate salt water intrusion. Locally, reinjection of treated groundwater is taking place at Otis Air Force base on Cape Cod.

Although none of these situations match the Barnstable project in all aspects (injecting municipal wastewater into a shallow, unconsolidated, utilized aquifer at rates up to 1,000 gallons per minute [gpm]), each situation did offer information, which helped evaluate the feasibility of injection at Barnstable. Four different injection scenarios that were considered prior to proceeding with and designing the Barnstable pilot test are discussed below.

MUNICIPAL WASTEWATER INJECTION – FLORIDA

Deep well injection of treated wastewater has been practiced in Florida for over 25 years. Currently, there are approximately 47 injection wells in southern Florida. Injected water must either meet primary drinking water standards at the point of discharge or be into an aquifer with groundwater containing a TDS concentration of 10,000 ppm or more. In Broward County, 18 injection wells dispose of 110 mgd of treated wastewater (an average of 6 mgd, or 4,200 gpm per well). In Florida, these wells are regulated as Class I wells, a designation typically assigned to hazardous waste disposal wells. Literature describing the use of this technology claims a disposal cost of approximately $0.23/1,000 gallons. This was compared to $0.38/1,000 gallons for an ocean outfall. In Florida, tertiary treatment (advanced wastewater treatment) is required for surface discharge. This can bring the cost of surface discharge to $1.50/1,000 gallons.

The North Regional Facility of Broward County injects about 60 mgd through four 24-inch injection wells spaced about 300 feet apart. Wastewater is injected into the Boulder Zone at a depth of about 3,000 feet. The Boulder Zone is a saline aquifer approximately 2,500 feet deeper than the Biscayne Aquifer, the source of water in the area. Prior to injection, the wastewater undergoes secondary treatment. BOD is reduced to approximately 5 ppm, and TSS is reduced to less than 5 ppm.

There are currently two hurdles to the operation of wells in Broward County. Despite injection into extremely fractured rock, the facility has experienced formation plugging and a buildup of injection pressure, which reduces the injection capacity of the system. Various treatments are applied to maintain the injectivity of the system. Batch superchlorination aids in cleaning up biological slimes that collect on the well casing and injection face. Backflushing is used to clear up the vugs and fractures into which the wastewater is being injected. Because of the pressure in the injection zone, the wells will backflush themselves. Physical treatment (i.e., scraping the casing) has proven to be somewhat effective. Physical and chemical treatment of the injection zone (acidizing or scraping) has not been particularly effective.

Greater levels of treatment are not considered economically feasible. Filtering and high-level disinfection, currently not part of the process, could amount to a plant upgrade that would cost between $100 and $150 million at the North Regional Facility. Currently, there is no nutrient removal, but that is not considered to be an operational issue.

The second hurdle relates to regulatory and public acceptance of the technology. Although wastewater injection wells have been used for nearly 25 years and are permitted by the state, recent negative public opinion has resulted in enhanced scrutiny by USEPA and FDEP. USEPA has been sued by the Legal Environmental Assistance Foundation (LEAF) because of the potential environmental and health effects of deep well injection. USEPA is responding to the suit and FDEP is also evaluating the suitability of the technology. The concern of LEAF is that it cannot be demonstrated that the Biscayne Aquifer and the Floridan Aquifer (still defined as a USDW although not used as a source of potable water in this area) are hydraulically isolated from the injection zone.

The City of Hollywood, Florida is currently investigating the potential use of treated effluent to mitigate salt water intrusion by injection into the Biscayne Aquifer. Because of the increased use of groundwater in coastal Florida, groundwater levels near the coast have dropped about 4 feet, resulting in salt water intrusion inland. There is some concern about the Hollywood plan. A pilot test using treated effluent was being considered, but was deferred until a pilot test using potable water was first completed. Hollywood is proposing injection at a sufficient depth (135 to 165 feet) so that injection will be into an aquifer with groundwater having a TDS concentration greater than 10,000 ppm, the regulatory threshold defining a USDW. Twelve injection wells are planned to be located 1/4 mile apart and each is designed to handle 1 to 1.5 million gallons per day. The aquifer is highly transmissive (between 5 and 10 million ft^2/day), thus allowing such high injection rates. The Biscayne Aquifer is a highly fractured and vugular limestone. In the opinion of the operator, the greatest hurdle to maintaining an effective injection system is the buildup of biological slimes and plugging. Avoiding iron-based tubulars was recommended to mitigate buildup of iron bacteria. Physical plugging is not considered to be as significant an issue.

Wastewater injection in Florida differs from wastewater injection on Cape Cod in that:

- Injection in Florida is to a depth of approximately 3,000 feet, below any USDWs and most likely separated from the USDWs by confining layers, as compared to the injection depth of 60 feet for the pilot test.

- Injection is into consolidated fractured rock rather than unconsolidated sands.

- Injection is through open hole completions rather than through well screens, as would be required in Barnstable.

- Water table mounding is not an issue because the water table is isolated from the injection zone.

Similarities include the like chemistry of the two wastewaters; both undergo secondary treatment; TSS loading and plugging of the receiving zone are concerns that have to be managed; and regulatory and public acceptance may be an issue.

TREATED GROUNDWATER REINJECTION – MASSACHUSETTS MILITARY RESERVATION (MMR)

Since August 1997, MMR has been operating a groundwater pump-and-treat system that reinjects treated groundwater back into the subsurface using injection wells. At the time of the review, the system operated at a flow rate of approximately 350 gpm (.5 mgd). Groundwater extraction was accomplished with ten 8-inch withdrawal wells. Eight operated at 30 gpm and two operated at 57 gpm. Injection was through eight 6-inch wells operated at approximately 44 gpm. The injection wells are spaced in two lines with four wells in each line. Wells in each line are separated by 50 to 100 feet and the two lines are separated by a space of about 500 feet. The two lines of injection wells are located at either end of the line of extraction wells and are approximately 200 feet downgradient. The depth to water at the injection site is approximately 40 feet. Mounding of approximately .5 feet was observed despite the proximity of the injection wells to the withdrawal wells. The wells are 45 to 95 feet deep and are screened over the bottom 40 feet of the well. The well screens have slot sizes of .050 or .030 inch. The injection interval has a hydraulic conductivity of approximately 300 feet per day. The injection wells are constructed of PVC with gravel packed stainless steel screens. Extracted water was treated for

VOCs using activated carbon. Water is treated with potassium permanganate to raise the pH in order to precipitate iron and manganese. Prior to precipitation, there was approximately 1.7 ppm total iron and manganese. Following precipitation, that concentration was reduced to approximately .02 ppm. The water is filtered through a green sand filter before injection. Precipitation is performed ahead of all treatment systems to minimize plugging in the carbon. Biodegradation of petroleum products in the treated plume resulted in higher than background levels of metals in the influent groundwater coming into the treatment system.

Despite the precipitation of metals and filtering, some plugging of the injection wells had been observed. The reduction in injectivity was attributed to encrustation of the well screens and plugging of the aquifer matrix. The plugging was attributed to possible additional precipitation as a result of a higher oxygen content in the injected water. No analyses had been performed to characterize the plugging. As the wells inject by gravity flow, the plugging was indicated by an increase in the water level in the wells rather than a buildup of injection pressure.

Injection at MMR differs from potential injection at Barnstable because:

- The quantities are so much less -- 350 gpm as compared to 700 to 1000 gpm ultimately planned for Barnstable.

- Injection is in very close proximity to the extraction wells at MMR, minimizing the hydraulic impacts (mounding).

- Nutrient loading and migration are not an issue at MMR because treated groundwater, not wastewater, is being injected.

- Process impacts of municipal wastewater treatment (pH and O level adjustments) are not the same at MMR as they would be at Barnstable.

- MMR precipitates metals out of the water prior to any other treatment or process to minimize impacts on process equipment. This has the secondary benefit of minimizing TDS in the effluent stream.

The MMR situation is similar to Barnstable in that it occurs in the same aquifer with presumably similar hydraulic properties. Prior to design and construction of the MMR treatment system,

injection tests of up to 500 gpm in a single well were conducted. Results of this testing, as well as associated hydraulic modeling, provided insights related to the Barnstable pilot test design such as potential injection rate, well design and operational parameters

RECYCLED WATER REINJECTION - ORANGE COUNTY, CALIFORNIA

Excessive pumping of groundwater resources in Orange County has resulted in a lowering of the water table in coastal areas and subsequent salt water intrusion. As early as the 1950s, salt water had migrated as far as 5 miles inland. A primary area where this has occurred is the Talbot Gap, the buried mouth of an alluvial fan between Newport Beach and Huntington Beach. In a project referred to as Water Factory 21, approximately 22.6 mgd are injected into 23 multipoint injection wells located about 600 feet apart. The 22.6 mgd injected is derived from approximately 14 mgd of treated effluent from the OCSD and 8.6 mgd derived from deep well water. Five mgd from the OCSD undergoes reverse osmosis, and the other 9 mgd undergo carbon adsorption. The resulting product water meets California Department of Health Services' primary and secondary drinking water standards. The total treatment process includes chemical clarification, recarbonation, multimedia filtration, granular activated carbon, reverse osmosis, chlorination, and blending. Total treatment cost is approximately $6 per 1,000 gallons. Injection is through 150 wells that range in depth from 280 to 700 feet. Some of the injected water flows oceanward, creating a salt water intrusion barrier, and most of the injected water flows inland, replenishing well fields.

The California project differs from Barnstable in that much greater quantities of water are being injected and the water is treated to an extremely high level. The California project is similar in that injection is into a utilized aquifer. Orange County is currently developing a $350 to $400 million project to more fully utilize treated water, referred to as the Groundwater Replenishment System.

WASTEWATER REINJECTION TO MITIGATE SALT WATER INTRUSION -- PILOT TEST ON LONG ISLAND

Between the 1960s and 1980s, the Nassau County Department of Environmental Protection and the United States Geologic Survey conducted pilot tests on the southern side of Long Island to study the feasibility of injecting treated wastewater to mitigate salt water intrusion. The tests took place in two phases. In both cases, the water underwent tertiary treatment. During the first

set of tests in Bay Park, treated water was injected into the Magothy Formation, comprised of unconsolidated silts and fine sands at a depth of approximately 480 feet. Between 200 and 400 gpm were injected into a single 8-inch fiberglass injection well with a stainless steel screen. Injectivity began to decline after about a month, but injection continued for about six months before the well needed to be treated. Plugging was attributed to a high suspended solids load in the effluent. Injectivity was restored by letting the well backflow for approximately one hour, which served to clear out the pore space adjacent to the well. In the 1980s, similar testing was performed at East Meadow. At that location, treated effluent was injected into the Upper Glacial aquifer at a depth of 200 feet and was also recharged via recharge basins. The pilot tests were completed, but a full-scale system was never implemented because it was determined that salt water intrusion had not become a significant enough issue to warrant the expense.

AQUIFER STORAGE-RECOVERY (ASR)

In some regions of the country, potable water is processed and is then injected back into the ground for storage for use during dry periods when the usual surface water or groundwater supplies become diminished. A great deal of research has been conducted into the operation of these ASR wells. Although the ASR wells are injecting potable water, not treated wastewater, a number of operational issues are similar, including well mechanics, injection rate and pressure, plugging, and water quality impacts. Much of the research related to ASR wells is applicable to design considerations for a wastewater injection well.

SUMMARY OF TECHNOLOGY REVIEW

Four cases of injection of treated water were reviewed to assist in evaluating the feasibility of injecting treated effluent at Barnstable. There are no precedent projects that are identical to the situation at Barnstable, so it was necessary to gain available information from the similar projects and apply that information to the Barnstable project.

A. **Regulatory Issues.** All of the reviewed programs were being completed in compliance with local and federal regulations. MADEP was aware of all aspects of this project, both in terms of the Bureau of Resource Protection and the State UIC (Underground Injection Control) programs. Also, MADEP informed USEPA of the project. All involved regulatory groups have been supportive of the project.

B. **Public Concern.** Public concern was not identified as an issue at any site except Florida. Barnstable residents can take comfort in the fact that wastewater has historically been recharged to groundwater and that the wells are only another mechanism to achieve the same goal.

C. **Operations.** The common operational concern that affects or potentially affects all systems and will be a factor with Barnstable is the decline in injectivity as a result of plugging. In the Long Island pilot tests, it was apparently precipitation of mineral solids that caused plugging. In all other cases, biological fouling was cited as the likely cause for loss of injectivity. Florida manages this through superchlorination and mechanical cleaning of the wells. Stearns & Wheler knew that plugging was going to be a potential problem during the test. The objectives of the test included identifying and addressing plugging mechanisms that could impact operation. Filtration, disinfection, and well design were all based on this knowledge. Responses to plugging were not included in the work plan because it was not certain that plugging would occur (every geologic setting and wastestream is a unique situation) and the plan was to see what problems arose and then address them specifically and appropriately.

D. **Hydraulic Issues.** is the Town of Barnstable was concerned that the treatment plant could elevate the water table to a point that impacts the surface, either through flooding basements, causing ponding or impacting water levels at ponds or lakes. This was not an issue at any of the other sites with the exception of MMR. At MMR, there was enough concern to monitor water levels, but because of the relatively low quantities being reinjected and because reinjection is occurring near withdrawal wells, mounding was not a significant issue. Water table levels had increased by about .5 feet at the MMR injection site. At Barnstable, impacts to the level of the water table are a primary concern.

E. **Health and Environmental Issues.** As a rule, injection in Florida is into zones that underlie, and that are likely separate from, USDWs. In the instance of the Hollywood pumping test, regulators suggested that the pilot test first be conducted with potable water. In California, injection is into a USDW, but the water is highly treated. At MMR, the effluent is not treated municipal wastewater with the associated concerns regarding bacteriological pathogens and nutrients. If Barnstable wishes to inject wastewater that has undergone secondary treatment into USDWs, either inside or outside of Zones of Contribution of municipal supply wells, sufficient demonstration of no significant health or environmental impacts will have to be made by the Town during a permitting process. Specifically, compliance with MADEP's and EOEA's Interim Guidelines on Reclaimed Water will have to be demonstrated

F. **Summary.** Based on the information summarized above, subsurface injection may be a viable alternative for disposal of treated municipal wastewater in Barnstable. There are three primary motivators for considering subsurface injection:

1. Replenishing the groundwater resources of Cape Cod (as does rapid bed infiltration). This goal eliminates deep well injection below a USDW as an alternative because it would not meet the Barnstable and MADEP shared objective.

2. A significantly reduced acreage requirement or aesthetic disruption.

3. Considerably less cost.

Hurdles to overcome are:

1. Operational difficulties in terms of plugging, which can be caused by injection solids, air entrainment or biological plugging, and maintaining injectivity.

2. Demonstrating that the technology is as protective of human health and the environment as rapid bed infiltration.

3. Demonstrating that a more concentrated source area will not result in unacceptable hydraulic impacts.

Considering the motivators and hurdles to overcome, and in view of the information gathered related to other injection scenarios, pilot testing to evaluate the applicability of the technology was determined to be warranted, and design and execution of the pilot test proceeded.

Appendix B
Well Design Considerations

APPENDIX B

WELL DESIGN CONSIDERATIONS

The design of the well was based on logs from existing wells at the site, design specifications of production wells in the area, literature available on the design of injection wells, and information gained from a comparable injection well test at MMR. A pilot boring was installed at the location of the injection well to allow the collection of sediment samples so that screen length, depth, and slot size could be determined.

There were three limiters to the rate that water could be injected, including:

1. A high water table that limits mounding to an elevation that would not impact surface water bodies or subsurface structures and would not cause ponding.

2. The rate at which the receiving formation could accept water

3. The mechanics of the well, including its diameter, screen length, and screen slot size.

Due to its high transmissivity, the aquifer was able to receive a significant quantity of water and the well could be designed to transmit a significant quantity of water. Mounding impacts would probably be the first limiting factor. Therefore, the well design (the only one of the three limiters that can be engineered) should be able to convey enough water to meet but not exceed the amount permitted by the mounding limitation. At the time of design, it was not known what discharge rate would correspond to an acceptable level of mounding. Although modeling could serve as a guide, only the pilot test would be able to accurately define the maximum allowable injection rate.

Injection wells must be carefully designed because they are much more likely to fail than are pumping wells. As previously discussed, water chemistry, air entrainment, and mechanical plugging are common problems with injection wells. Solids concentrations as low as 1 mg/L can clog injection wells in a short time. A 6-inch test well in California pumping 32 gpm with 3.3 mg/L solids showed a 30 percent increase in injection pressure in 9 days. In one of the case

histories reviewed, an injection well operated for six months, and the head in the well rose by 6 feet even though the water contained only .004 mg/L solids.

The design of injection wells is similar to pumping wells with the exception of entrance velocity and screen length. Because of concerns with plugging, optimizing screen opening area (slot size and screen length) is critical. Production wells are typically designed to have an entrance velocity of 0.1 ft/sec. The entrance velocity for an injection well should not exceed 0.05 ft/.sec. Therefore, everything else being equal, the open area of a screen for an injection well needs to be twice that of a production well. Minimizing pressure buildup in an injection well is the primary objective of design and construction. Reducing pressure buildup decreases the number of wells required and increases the recharge rate per well.

The basis of design for determining the diameter and screen length was derived from investigating production wells in the area. A rule of thumb is that an injection well to convey X gpm would be comparable to a production well designed to convey 2X gpm. The smallest municipal well (West Barnstable Fire District) in the area has an 8-inch screen that is 10 feet long. That well can convey approximately 700 gpm (just over 1 mgd). Most other production wells in the district have 24-inch screens that are 5 to 20 feet long. Production rates range from 300 to 1000 gpm. The assumption that 350 to 500 gpm can be injected into a 10-inch by 30-foot screen seemed reasonable based on the capacities of the production wells in the area.

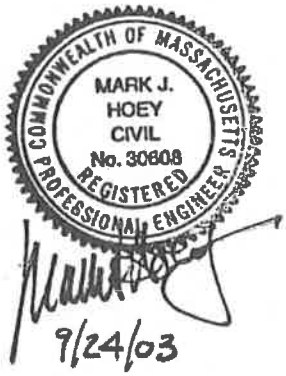
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension Preliminary Design Report; September 2003

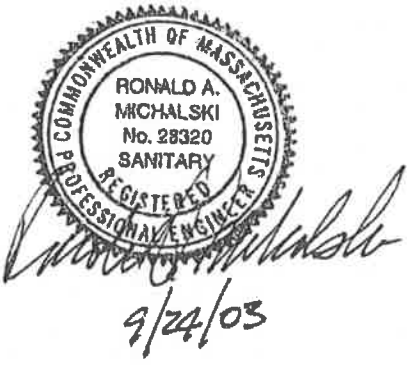
Final

Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

Preliminary Design Report

Town of Barnstable
Department of
Public Works





September, 2003

Submitted by

Tighe&Bond

Barnstable is a Cape Cod community with a wealth of water resources in the form of lakes, harbors, embayments and an extensive coastline along Nantucket Sound. For a number of years, Barnstable has been studying the water pollution control needs of the community because a majority of the Town is served by septic tanks with leach fields that discharge treated sewage to the ground. The exception is Hyannis, where the developed, downtown area is served by a municipal sewerage system with a modern wastewater treatment facility.

The most recent, ongoing sewer study or Comprehensive Wastewater Management Plan has identified a number of community areas where on-site septic systems are contributing to elevated nitrogen levels in local water resources. The term "Area of Concern" (AOC) was developed in the recent sewer study and is used to identify specific areas of the community where water pollution control needs are most obvious and can only be mitigated by extending the municipal sewerage system so that septic systems can be abandoned, sewage collected and eventually treated at an appropriate wastewater treatment facility.

The ongoing Comprehensive Wastewater Management Plan (CWMP) has identified the Lake Wequaquet/Long Pond area of the community as an AOC and has confirmed the need for sewer extensions to serve the area. The CWMP process reviewed a variety of sewer extension options for the Lake Wequaquet/Long Pond area but concluded that a more detailed analysis was needed to develop a cost-effective and environmentally sensitive sewer extension program. As a point of interest, the Barnstable CWMP process identified a number of AOC's and acknowledged that a detailed layout of sewer extensions to each area was beyond the limits of the general planning effort.

The Preliminary Design Report that follows focuses on the Lake Wequaquet/Long Pond area and has one primary purpose: to determine the most economical and environmentally sensitive sewer extension program to serve the area. The Preliminary Design Report includes an analysis of the sewerage extension needs of Cape Cod Community College, which is located just outside of the AOC but is a State facility that needs to mitigate concerns associated with its existing on-site septic systems.

Barnstable has authorized $1,200,000 for the preliminary and final design for the Lake Wequaquet/Long Pond sewer extension program and retained Tighe & Bond Consulting Engineers in the summer of 2002 to work on the evaluation. Over the last eight months, the engineer has reviewed the topography of the AOC, existing development patterns, the number of homes within the AOC, the location of potential connection points to the existing Barnstable sewerage system, the sewerage needs of areas directly adjacent to the AOC, the street and private way layouts that serve the area, and the existing utilities that may impact the construction of municipal sewer extensions.

Using available data, the engineer evaluated four different comprehensive sewer layouts to serve the AOC and eventually recommended Alternative 3 (or 3A if the grinder pumps are purchased and maintained by the residents), a sewer layout that consists of a combination of gravity sewers, five pumping stations, low pressure sewers and 598 grinder pumps to provide sewer service to the AOC. This alternative includes the installation of 120,200 feet of sewer pipe consisting of 36,200 feet of gravity sewer and 62,800 feet of low pressure sewer to be constructed in existing streets and public ways. A complete description of all alternatives that were evaluated, including additional information on the recommended alternative, can be found in Section 12, Summary and Recommendations.

The total estimated construction cost of the recommended alternative is $17,797,000 (engineering costs are not included) and will serve 1,315 properties. Excluding grinder pump costs, the total estimated construction cost of the recommended alternative is $13,312,000. In addition, the alternative provides design flexibility to serve additional Barnstable areas that are adjacent to the AOC and recommends improvements to the existing municipal sewerage system so that sewage flows from the AOC can be transported to and treated at the existing Hyannis wastewater treatment facility.

As part of the extensive review work associated with the evaluation of all sewer alternatives during this study, the following additional criteria were incorporated into the final recommendation:

- Environmental impacts (water quality, wetlands, rare species, etc.),
- Neighborhood impacts (aesthetics, traffic, noise, air quality, land acquisition needs, etc.),
- Sewerage system operating costs,
- Private home information regarding plumbing features and septic tank locations,
- Sewer system reliability, and
- Sewer system expandability.

The Preliminary Design Report also includes extensive discussions about various sewer extension technologies, reviews a variety of municipal sewerage pumping station construction options, provides information on grinder pumps that are an integral part of a low pressure sewerage system, and provides preliminary siting information for the five pumping stations that are included in the recommended alternative. Finally, the engineering effort also includes the development of a project-specific website that is

located at http://projects.tighebond.com and contains project information that can be accessed by the public.

Finally, the Preliminary Design Report recommends that Barnstable proceed with the Final Design of the recommended project with a goal of having complete design plans and specifications for the project ready in the summer of 2004 so that Barnstable can initiate the construction phase of the project in a timely manner.

Tighe & Bond would like to take this opportunity to thank a number of municipal officials who assisted during the preliminary design engineering effort including Bob Burgmann, P. E., Town Engineer; Mark Giordano, P. E. Senior Project Manager in the Department of Public Works; Peter Doyle, Water Pollution Control Facility Supervisor; Jack Harris, Project Manager; and Dr. Paul Canniff, a representative of the Lake Wequaquet Association. The municipal officials provided valuable assistance, guidance and input during the preparation of this preliminary engineering report.

1.1 PURPOSE

This report presents a sewer extension evaluation performed for the neighborhoods surrounding Lake Wequaquet, Long Pond, Bearse Pond and Shallow Pond in the Town of Barnstable as well as for the Cape Cod Community College. The purpose of this report is to determine the most economical preliminary sewer extension design, which can be used as the basis for the development of detailed construction contract documents.

Previous facilities planning efforts identified several areas of environmental concern in Barnstable, including the Lake Wequaquet and Long Pond areas. Lake Wequaquet, Bearse Pond, Shallow Pond, and Long Pond are important natural resources in the area, as described below:

1. The Lake Wequaquet/Long Pond area is within the state approved Zone II groundwater protection area.

2. There are several wetland resources in the Lake Wequaquet/Long Pond area.

3. There are priority habitats of rare species and estimated habitats of rare wildlife throughout the Lake Wequaquet/Long Pond area.

4. These fresh water bodies are used for recreational purposes, including swimming, fishing, and boating.

5. The scenic nature of these water bodies has a positive impact on the quality of life of the nearby residents and draws both residents and non-residents to their shores. In fact, the scenic and recreational qualities of the Town are the foundation of the economy, which include tourism, vacation, and retirement homes.

A reduction in water quality has been observed in Lake Wequaquet and Long Pond, primarily due to high nutrient loadings, as is documented through prior planning efforts. Septic system discharges were determined to be a major source of these nutrient loadings. The nutrient loadings can affect surface water quality, natural resources, and human use of these resources. High nutrient loadings to surface water bodies can result in excessive growths of algae and aquatic plants that deteriorate the water environment (eutrophication). Secondary effects can include a change in biota, a buildup of organic material, low dissolved oxygen levels, fish and shellfish mortality, and increased bacteria levels.

The proposed project will implement facilities planning recommendations to provide sewer service to the neighborhoods surrounding Lake Wequaquet, Long Pond, Bearse Pond and Shallow Pond, eliminating the septic systems within this area of concern.

As noted above, this report also includes a sewer extension evaluation for the Cape Cod Community College, which is currently served by several septic systems. The college is currently designing a pump station to collect and then discharge its wastewater flow into the Town's collection system. The pump station force main route and Town sewerage system connection point has been investigated as part of this evaluation.

1.2 SCOPE

The following tasks were performed as part of this evaluation and are described in this report:

1. Reviewed existing background information
2. Developed mapping of the study area
3. Reviewed prior planning efforts
4. Reviewed sewer service layout questionnaires sent to each property owner within the AOC
5. Determined current wastewater flows in the study area
6. Projected future wastewater flows in the study area
7. Evaluated potential connection points to the existing sewerage system
8. Developed and evaluated sewer layout alternatives
9. Provided the Town with sewer extension recommendations
10. Assisted the Town with a Public Participation Program
11. Performed an assessment of the environmental and neighborhood impacts of the sewer extension alternatives and determined the permits expected to be required
12. Performed an assessment of traffic impacts
13. Collected information on existing utilities within the project area

2.1 DESCRIPTION OF PROJECT AREA

2.1.1 General

The project area has been divided into three parts in this evaluation:

1. The Area of Concern
2. The "Bowl"
3. Cape Cod Community College

Each of these areas is described below. A general street map of the project area is presented in Figure 2-1.

2.1.2 Area of Concern

The Area of Concern (AOC) has been defined by the Town, based on previous evaluations, and includes the neighborhoods surrounding Lake Wequaquet, Long Pond, Bearse Pond and Shallow Pond, as shown in Figure 2-2. The preliminary design developed provides sewer service to each resident within the AOC.

The AOC surrounding Lake Wequaquet, Bearse Pond and Shallow Pond is generally bounded by Shootflying Hill Road to the west and northwest, Route 132 to the northeast, Phinney's Lane to the east and southeast, and Great Marsh Road to the southwest. The AOC surrounding Long Pond is generally bounded by Route 28 and West Main Street to the north, Childs Street to the east, Pine Street to the south, and Main Street and Phinney's Lane to the west.

2.1.3 The Bowl

The area that drains toward Lake Wequaquet, Long Pond, Bearse Pond, and Shallow Pond, but is outside of the AOC, was also determined as part of this evaluation. This area is described as the "Bowl" for the purposes of this evaluation and is also shown in Figure 2-2. Although sewer service is not currently planned for this area, it is anticipated that if future sewer service is provided to the Bowl that the wastewater from this area would flow into the new sewers that are proposed in the AOC. As such, the new gravity and vacuum sewers proposed within the AOC have been sized to accommodate wastewater flow from the Bowl. Because low pressure sewers are not readily expanded, the low pressure sewers proposed have been sized to serve only properties within the AOC and properties adjacent to proposed sewers. This is discussed in greater detail in subsequent report sections.

SCALE: 1"=1200'

DATE: MARCH 2003

The Bowl surrounding Lake Wequaquet, Bearse Pond and Shallow Pond is generally bounded by Oak Street to the northwest, Route 6 and Route 132 to the north, Phinney's Lane to the east, Wequaquet Lane to the southeast, Route 28 to the south, Old Stage Road to the southwest, and Shootflying Hill Road to the west. The Bowl surrounding Long Pond is generally bounded by Route 28 and West Main Street to the north, Old Strawberry Hill Road and Strawberry Hill Road to the east, Pine Street to the south, and Main Street and Phinney's Lane to the west.

2.1.4 The Cape Cod Community College

The Cape Cod Community College is located off of Route 132, just north of the Route 132/Route 6 intersection. The college is currently designing improvements to its existing wastewater collection system and a new wastewater pump station, which will allow it to abandon its existing septic systems once a connection can be made to the Town sewerage system. Layouts that convey the pumped flow via a new force main from the college to the Town sewerage system were evaluated as part of this evaluation.

2.2 PREVIOUS STUDY WORK

A wastewater facilities plan was developed for the Town of Barnstable and was performed in three phases. This work is described in the following documents:

1. *Wastewater Facilities Plan Phase I, Needs Assessment Report, Town of Barnstable, MA*, prepared by Stearns & Wheler and dated December 1993.

2. *Wastewater Facilities Plan Phase II Interim Report, Town of Barnstable,* prepared by Stearns & Wheler and dated December 15, 1994.

3. *Wastewater Facilities Plan, Town of Barnstable, Draft Phase III Sections,* prepared by Stearns & Wheler and dated June 21, 1996.

2.2.1 Phase I Facilities Plan Report

In the Phase I report, existing and future land use and demographics were used to determine existing wastewater flows and project future wastewater flows and loadings in the Town of Barnstable for the Year 2014. Wastewater issues and specific problem areas were identified and evaluated. In addition, the existing sewerage system was reviewed. The Town was divided into several sub-areas in the Phase I report. Area CE4, established in the Phase I report, matches the AOC defined by the Town for the Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension Project.

Regulatory issues related to wastewater disposal were identified in the Phase I report, including especially the nitrogen removal requirement included in the Water Pollution Control Facility's (WPCF's) draft groundwater discharge permit. Several areas of environmental concern were identified, including:

- Groundwater zones of contribution to public water supply wells (Zone II areas)
- Freshwater bodies and their recharge areas
- Coastal resources
- Wetland buffers
- Rare and endangered wildlife and plant habitat

Many of the Town's natural resources and environmentally sensitive areas were reported to have had problems attributable to the disposal of wastewater, boat waste and stormwater, resulting in the eutrophication of several water bodies. In particular, Area CE4 was identified as an area of environmental concern. Area CE4 is within a Zone II wellhead protection area, includes wetlands and wetland buffer areas, is in a FEMA flood area, is a coastal resource (shellfish, finfish), is a critical recharge area (area contributing groundwater to a sensitive receptor), and is a wildlife and plant habitat.

Failing on-site wastewater disposal systems (cesspools or septic tanks and leaching fields) were identified throughout Barnstable, including in Area CE4, and the causes identified included small lot size, poor soils, high groundwater, and substandard treatment (cesspools). It was reported that greater than 65% of the houses in Area CE4 were built prior to the establishment of the Massachusetts Title 5 Regulations and/or Barnstable Board of Health Regulations. The Phase I report indicated that many of these lots would not meet current State and/or Town septic system regulations.

Current and projected future wastewater flows were determined for the Town, and for Area CE4 in particular, using water use data and population estimates. The population estimates and wastewater flows for Area CE4 are summarized in Table 2-1:

Table 2-1

Area CE4 Population and Wastewater Flow Estimates

Current Conditions		Future Conditions (Year 2014)	
Max. Month Population	Max. Month Wastewater Flow (gpd) [1]	Max. Month Population	Max. Month Wastewater Flow (gpd) [1]
1,717	152,000	2,070	178,000

Notes:

(1) Includes commercial and industrial wastewater flows, which were also determined using water use data.

Based upon a review of the existing collection system, the 10-inch sewers on South Street, the 10-inch sewers on Pleasant Street, the 10-inch sewers on Center Street, and the 8-inch sewers on Sea Street were determined to be hydraulically overloaded under summer flow conditions. The trunk line on West Main Street was determined to be adequately sized for current conditions but to have little excess capacity for future expansion.

2.2.2 Phase II Facilities Plan Report

The Phase II report presented alternatives to address wastewater problems identified in the Phase I report. Sewerage system improvements considered included:

1. Decentralized wastewater treatment and disposal, ranging from upgrading existing septic systems to constructing neighborhood treatment and disposal systems

2. Centralized wastewater treatment and disposal at the existing Hyannis Water Pollution Control Facility (WPCF)

3. Wastewater collection system improvements, including alternatives to sewer areas that are currently unsewered and upgrading the existing collection system

4. Residuals management improvements, including treatment and disposal of residuals within the Town and treatment and disposal of residuals at a regional facility

5. Improvements to the Hyannis WPCF treated effluent groundwater discharge

Alternatives were screened in the Phase II report using a standard set of criteria in order to determine the most feasible alternatives. The alternatives selected were evaluated in greater detail in the Phase III report.

Several additional areas of concern were identified in the Phase II report, based on nitrogen loading modeling performed by the Cape Cod Commission, which was used to predict nitrate-nitrogen concentrations in the public water supply wells. Note in particular that Areas CO7 and BWST1, which were identified as areas of concern using the nitrogen loading model, overlap with Area CE4, which is the focus of this Preliminary Design Report.

Of most interest to this current evaluation was the screening of collection system alternatives for Area CE4. Four types of collection systems were considered, including gravity sewers, pressure sewers, septic tank effluent sewers (septic tank effluent pump systems and small diameter gravity sewers), and vacuum sewers. Vacuum sewers were

dropped from consideration in the Phase II report because of concerns regarding high capital costs, high maintenance, the need for significant staff training, limited expandability, and the need for greater accuracy in estimating initial flows. In addition, it was noted that the technology is not established or well proven.

An alternative consisting entirely of gravity sewers was considered economically impractical due to the topography around Lake Wequaquet and the other water bodies in Area CE4. An alternative consisting entirely of pressure sewers was considered for Area CE4 as well as two combination gravity sewer/pressure sewer alternatives. The first combination alternative included eight pump stations and would provide gravity service to many of the residents in Area CE4. The second combination alternative included more pressure sewers in order to reduce the number of pump stations needed to four. Connection points to the existing sewerage system on Old Strawberry Hill Road, West Main Street, and Route 28 were considered. The Phase II report recommended that only the entirely low pressure sewer alternative and the combination alternative with four pump stations be evaluated in the Phase III report for Area CE4. The eight pump station combination alternative was dropped from consideration because of the perceived high operation and maintenance costs.

The Phase II report indicated that improvements to the existing sewerage system were recommended in a 1987 Wastewater Management Report to improve existing conditions and allow for new sewer extensions. Some of the major recommendations in that report included:

1. A 16-inch relief sewer on Pleasant Street, Center Street and South Streets to relieve the overloaded lines

2. Diverting the discharge from the West Main Street pump station from South Street directly to the wastewater treatment facility

3. Reconstruction of the West Main Street pump station

The 1987 report also recommended sewering all of the areas within the zones of contribution of the public water supply wells.

The Phase II report confirmed that there are existing sewer segments with restricted capacity on South Street (10-inch, 12-inch, and 15-inch), Center Street (10-inch), Pleasant Street (10-inch), and West Main Street (12-inch). In addition, the impact of infilling and new sewer connections on the existing sewerage system were evaluated. In particular, the Phase II report indicated that if CE4 were connected to the existing sewerage system that the 10-inch, 12-inch, and 15-inch sewers on South Street would not have adequate hydraulic capacity, under current and future flow conditions.

2.2.3 Phase III Facilities Plan Report

The Phase III report provided cost estimates for the feasible alternatives developed in the Phase II report. The Phase III report also provided information on the cost evaluation approaches and criteria used for the various improvement alternatives.

The areas of concern identified in the Phase I and Phase II reports were prioritized in the Phase III report based on the number of failed septic systems, location in a Zone II of a public water supply well, potential impact on freshwater and coastal water habitat, and conformance with Title 5 Regulations. Area CE4 was ranked second out of twelve areas. The Cape Cod Community College force main was ranked last out of the twelve areas.

The Area CE4 wastewater disposal improvements alternative with the lowest present worth cost was determined to be conveying the wastewater flow from CE4 to the existing sewerage system. The construction of decentralized treatment facilities was also considered but was determined to be more expensive. Single unit Title 5 septic systems were considered but were determined to not be feasible for many lots without significant variances from the Board of Health.

The capital cost to sewer Area CE4 and convey the wastewater flow to the existing sewerage system was estimated as $10,200,000 and the total present worth cost was estimated as $12,600,000. Note that grinder pump costs were not specifically identified in the facilities plan estimate. The maximum month wastewater flow from Area CE4 was estimated as 190,000 gpd. Note that the maximum month flow presented in the Phase I report is 178,000 gpd. No explanation was provided for the difference between the maximum month flow presented in the Phase I report and the maximum month flow presented in the Phase III report. Extending the West Main Street sewer around Long Pond was proposed to serve the southern portion of Area CE4 while a new gravity sewer on Route 132 was proposed to tie in parcels on the north side of Lake Wequaquet.

The following non-monetary considerations were identified:

- Connection to the Hyannis WPCF or a small treatment plant provides the highest level of treatment of the alternatives considered
- Sewering north of CE4 along Route 132 would potentially serve other commercial areas along Route 132 and the sewer could be used to tie in Cape Cod Community College
- Area CE4 overlaps Areas CO7 and BWST1, which were identified as areas with potential future groundwater nitrogen levels greater than 5 mg/l

- Sewering and treating at the Hyannis WPCF would remove some groundwater recharge

The Phase III report also included a needs assessment and alternatives evaluation for the Cape Cod Community College. The sanitary flows from the college were projected using water usage data from January 1991 to June 1996. Water usage was assumed to equal sanitary flow at the college because the college did not water athletic fields and had minimal non-sanitary water use.

The average annual water usage was reported as 2.92 million gallons per year from 1991 to 1995, which is approximately 8,000 gpd. Monthly water usage varied depending on the semester, with values exceeding 350,000 gallons (12,000 gpd) in the spring and fall, when the student population is greater, and much lower values in the summer. In addition, daily usage was reported to have exceeded 15,000 gpd seven times in 1996 during the months of January and February. Note that the implementation of water conservation measures was underway during the evaluation at the college and these measures were expected to reduce daily flows by approximately 4,000 gpd.

Daily water usage in 1996 was reported to range from 10,000 gpd to 13,000 gpd in the spring semester and from 4,000 gpd to 5,000 gpd in the summer semester. In comparison, tabular data presented in the Phase III report shows that the daily water usage ranged from 6,000 gpd to 16,600 gpd in the spring semester (12,100 gpd average) and from 2,000 gpd to 10,500 gpd in the summer semester (5,100 gpd average). Note that maximum daily summer usage typically did not exceed 6,000 gpd.

The then current college population was estimated in the Phase III report, based on enrollment information provided by the college for 1996, and is presented in Table 2-2 below:

Table 2-2
1996 Population Estimates – Cape Cod Community College

Season	Student Population	Staff Population	Total Population
Spring	3,500	450	3,950
Summer	1,200	350	1,550

Based on population and the projected daily flow ranges, a per capita flow rate range was established in the report of 2.5 to 3.3 gpcd (13,000 gpd/3,950 people) for the spring semester and 2.6 to 3.2 gpcd (5,000 gpd/1,550 people) for the summer semester.

Future growth at the college was projected in the 1996 Phase III report, based on the following:

- A student population growth of 5%/year over the planning period
- A staff population growth of 10% over the planning period
- The construction of a Technology Center, which would increase support staff by 2% and faculty by one person

The future maximum day spring sanitary flow is reported as 35,000 gpd in the 1996 Draft Phase III Facilities Plan. No peak hourly flow values are provided in the Phase III report.

Four alternatives for managing the wastewater needs of the college were developed and are described below:

Alternative No. 1	Continued use of the existing on-site systems
Alternative No. 2	Construction of a small wastewater treatment facility
Alternative No. 3	Connection to the Hyannis WPCF with a force main sewer
Alternative No. 4	Connection to the Hyannis WPCF with a force main and gravity sewer

Present worth costs were developed for each of the alternatives and are shown in Table 2-3 below:

Table 2-3
Present Worth Costs of Cape Cod Community College
Wastewater Management Alternatives

Alternative No.	Capital Cost	Annual O&M Cost	Total Present Worth Cost
1	$0	$4,200	$42,000
2	$1,840,000	$47,300	$2,310,000
3	$1,140,000	$35,000	$1,490,000
4	$1,530,000	$42,000	$1,950,000

Continued use of the existing on-site systems was determined to be the lowest cost alternative. However, this alternative requires that wastewater flows stay below

15,000 gpd in order to comply with Title 5 regulations and, as such, does not allow for future expansion. Construction of a new small wastewater treatment facility would have the highest cost of the four alternatives.

The following recommendations were made in the Phase III report for the college evaluation:

1. The college and the Town should meet to discuss the report results and the college's decision on wastewater management implementation

2. If the college and the Town decide that the college could connect to the Hyannis WPCF, the discussions should address the following questions:

   - Should a force main be constructed to the WPCF, or would the Town best be served if a combination force main and gravity sewer is built?

   - How much of the proposed force main and/or gravity sewer would the college be responsible to construct and maintain?

   - Can a long-term arrangement be negotiated between the Town and the college for wastewater treatment and disposal?

3. Continue with water conservation efforts

4. Continue to record water meter totalizer readings to establish long-term daily water consumption data

5. Consider adding an automatic recorder to obtain daily weekend and holiday water consumption

SECTION 3 SEWER SERVICE LAYOUT QUESTIONNAIRE

3.1 DESCRIPTION

A sewer service questionnaire was prepared and mailed to each homeowner in the Area of Concern (AOC) in order to obtain information on their septic systems and sewer pipes. The questionnaire package included a transmittal letter explaining the project and the purpose for the questionnaire, the questionnaire itself, and a map of the homeowner's property. The questionnaire and transmittal letter are included in Appendix A. The following information was requested in the questionnaire:

- Location of sewer discharge pipe, septic tank, and leachfield (to be marked on the attached map)
- Type of home (cape/standard, ranch, or raised ranch)
- Whether there is a cellar and the type (full cellar, finished cellar, or crawl space)
- Whether there are plumbing facilities in the basement and the type (sink, toilet, bath/shower, or other)
- How the sewer pipe exits the basement (through the wall or through the floor)
- The basement wall height and the height to the sewer if it exits through the wall

The information provided by these questionnaires has been used to determine whether the property owner can be served by a gravity sewer service or whether sewage pumping is required. In addition, the survey information will be used to guide the location of house service connections during design.

3.2 RESULTS

The questionnaire responses are summarized in Table 3-1. A total of 793 questionnaires were distributed within the AOC and 490 were returned, representing a 62% response rate. This is considered a good level of response for this type of survey effort. The homes that returned the questionnaire are shown on Figure 3-1.

A large percentage of the buildings in the AOC have full basements (73%), while only a small percentage have no basement (4%). The remainder of the building basements were crawl spaces. Information on basement heights, which averaged approximately 7 feet, provided an indication of minimum sewer depth where the sewer pipes exit the basement through the floor. However, at the vast majority of the homes (81%) the

sewer pipes exit the house through the basement wall rather than the floor. The location where the sewer exits the basement wall, which averaged approximately 3 feet below the first floor level, was also requested and was used to help determine if gravity service is possible.

Approximately 38% of the buildings had plumbing facilities in their basements. It may be necessary to pump the wastewater from these facilities to the collector sewer on the street, depending on collector sewer depth.

4.1 GENERAL

Current and projected future wastewater flow estimates for the AOC were developed in this report section. The wastewater flow projections were used to determine the appropriate size of new sewers needed to serve the AOC, which are shown in Section 6.

In addition, current and projected future wastewater flow estimates were developed for Cape Cod Community College, which currently utilizes septic systems for wastewater disposal. A wastewater pump station is currently being designed by another consultant that will allow the college to abandon its septic systems and pump all of its wastewater flow to the Town collection system for subsequent treatment at the municipal wastewater treatment facility. The piping size and layout from the college pump station to the Town collection system has been evaluated in this preliminary design report.

4.2 AOC

4.2.1 General

For the purposes of this evaluation, the AOC has been divided into 9 sub-areas, as shown on Figure 4-1. Current and projected future residential wastewater flows within the AOC were calculated for each sub-area using population estimates and per capita flow rates established during previous planning efforts and confirmed during this evaluation. Current commercial wastewater flows were estimated for each sub-area using recent water usage data.

Note that in some areas new sewers outside of the AOC have been proposed in order to convey wastewater from portions of the AOC to the existing sewerage system, as is detailed in Section 6. For example, in order to serve the southern portion of Long Pond, a sewer along Pine Street is proposed to convey wastewater from this portion of the AOC to the existing sewer system to the east. Barnstable officials have indicated that the homeowners along the street where this sewer is proposed may also be required (or if not required, allowed) to connect to the sewerage system, if there is available downstream hydraulic capacity. As such, homes outside of the AOC but adjacent to proposed sewers have been included in the development of current and future wastewater flows.

4.2.2 Current Conditions

The current maximum month residential population in the AOC has been estimated as 2,141 people, based on a count of the number of single-family homes (850) plus two multi-family homes (bed & breakfast inns) in the study area. We have assumed that there are, on average, 2.5 residents in each single-family household and 2 people per room in the bed & breakfast inns. Note that an average household size of 2.5 people was determined during the 1993 Phase 1 Facilities Planning. In addition, a total of 743 people (297 homes) are outside of the AOC but adjacent to the proposed sewers. As noted above, these residents may be required (or if not required, allowed) to connect to the proposed sewer, and, as such, have been included in the determination of current wastewater flows. In total, the current residential population to be served by the project is estimated as 2,884 people. A breakdown of the number of homes in each of the nine sub-areas is presented in Table B-1 in Appendix B.

The average daily residential sanitary flow was estimated by multiplying the estimated current population by an average per capita sanitary flow rate. The average per capita residential sanitary flow rate was determined in the Phase 1 Facilities Plan as 72 gallons per capita per day (gpcd) using water usage data. The average wastewater flow value was confirmed using recent pump operating data provide by the Town for the Marks' Path and Main Street pump stations. This comparison is presented in Appendix B.

The current maximum month average daily residential sanitary flow rate is calculated as approximately 207,700 gpd by multiplying 72 gpd/person by 2,884 people.

A total of 10 commercial facilities were identified in the AOC and 8 commercial facilities were identified outside of the AOC but adjacent to the proposed sewers. Commercial facilities in the Town have been classified using the criteria presented in the Phase I Facilities Plan. The three applicable commercial classifications are described below:

Type I — Designated for office space, banks, medical offices, and other commercial establishments that are expected to produce wastewater BOD_5 and TSS concentrations of less than 200 mg/l.

Type II — Designated for motels and hotels without restaurants, auto repair shops, service stations, bus facilities, marinas, and other commercial establishments expected to produce a wastewater with BOD_5 and TSS concentrations of 200 to 400 mg/l.

Type III — Designated for restaurants, bars, cafeterias, supermarkets, and other establishments expected to produce wastewater with BOD_5 and TSS concentrations of greater than 400 mg/l.

Average daily sanitary flows were estimated for the commercial facilities identified within the AOC and outside the AOC but adjacent to the proposed sewers using water usage data collected by the Town water districts in 2001 and 2002. For the purposes of this evaluation, we have assumed that 90% of the water usage is sanitary flow. Seasonal peaking factors were determined in the Phase I Facilities Plan report for the different types of commercial facilities, based on a review of seasonal population (for Type I facilities) and flow variations at the Barnstable Wastewater Treatment Facility (for Type II and Type III facilities). The maximum month average daily commercial sanitary flows are presented below in Table 4-1.

Table 4-1

Maximum Month Average Daily Commercial Sanitary Flows

Facility Type	Average Daily Flow (gpd)	Seasonal Peaking Factor	Maximum Month Average Daily Flow (gpd)
I	3,000	1.32	4,000
II	12,000	2.16	26,000
III	5,100	2.16	11,000
Total	**20,200**	---	**41,000**

As noted above, two bed & breakfast inns were identified during the evaluation, one in Sub-Area 1 and one in Sub-Area 7. These "commercial" facilities were treated as multi-family residential homes for the purpose of estimating wastewater flow with average daily flows of 720 gpd and 432 gpd for the Sub-Area 1 and 7 inns, respectively.

In total, the current maximum month average daily sanitary flow was calculated as 248,700 gpd by summing the residential and commercial flow components. The peak sanitary flow was calculated as approximately 994,800 gpd by multiplying the average daily sanitary flow by a peaking factor of 4.0. This peaking factor was determined based on the following:

- Tighe & Bond's experience estimating peak residential wastewater flows.
- *Technical Report No. 16, Guides for the Design of Wastewater Treatment Works*, 1998 edition, prepared by the New England Interstate Water Pollution Control Commission (commonly referred to as TR-16), which is often used as a guide for this type of work. A peaking factor of approximately 4.8 was graphically determined using Figure 2-1 in TR-16, based on the current average daily flow. We believe that the TR-16 peaking factor is more conservative than is necessary for most residential wastewater flows.

- *Recommended Standards for Wastewater Facilities*, 1997 edition, prepared by the Great Lakes-Upper Mississippi River Board of State and Provincial Public Health and Environmental Managers (commonly referred to as 10-State Standards), which is also often used as a guide for this type of work. A peaking factor of approximately 3.5 was graphically determined using Figure 1 in the 10-State Standards, based on the current population of 2,884 people.

If new sewers are constructed to serve the AOC, some infiltration of groundwater into the sewers can be expected and is normally considered in estimating flow quantities. For this evaluation, we have estimated infiltration rates by multiplying the typical infiltration value for new PVC sewers of 350 gpd per inch diameter per mile length of sewer (350 gpd/im), published in TR-16, by the estimated length of new gravity sewers and the predominant sewer size that would be constructed of 8 inches. We project the sewer infiltration rate within the AOC to be approximately 36,300 gpd, based on a gravity sewer length of approximately 68,300 linear feet. This length of new sewer is the greatest amount of gravity sewers anticipated of the four sewer layout alternatives.

The AOC average and peak wastewater flows were estimated as approximately 285,000 gpd and 1,031,100 gpd, respectively, by adding the projected sewer infiltration rate to the average and peak sanitary flows.

The average and peak wastewater flows estimated for each sub-area are summarized in Table 4-2.

4.2.3 Future Conditions

The projected future residential population at full build-out conditions was determined as part of this evaluation in order to size sewerage system components that will meet the long-term needs of Barnstable. The projected future residential population includes three components:

- Current residential population in AOC and outside of the AOC but adjacent to the proposed sewers (described in the previous report section)
- Future population in the AOC
- Current and future population in the Bowl

There are some open lots within the AOC where future development could occur. We have assumed that large lots would be sub-divided in the future to accommodate more homes and that construction would not occur in wetland areas. The sub-divided lots were sized to meet current zoning regulations for this area, which require a minimum lot size of 1 acre.

Table 4-2
Summary of Current Wastewater Flows to Proposed Sewers
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

Sub-Area	Gravity Pipe Length (lf) [1]	Infiltration (gpd) [2]	Average Wastewater Flow (gpd) [3]			Peak Wastewater Flow (gpd) [4]		
			AOC	Outside of AOC but Adjacent to Proposed Sewer	Total	AOC	Outside of AOC but Adjacent to Proposed Sewer	Total
1	6,800	3,600	18,200	4,100	22,300	62,000	16,400	78,400
2	7,300	3,900	11,800	7,000	18,800	35,500	28,000	63,500
3	10,900	5,800	21,100	7,400	28,500	67,000	29,600	96,600
4	7,500	4,000	25,100	5,800	30,900	88,400	23,200	111,600
5	5,200	2,800	11,100	8,300	19,400	36,000	33,200	69,200
6	6,100	3,200	15,300	500	15,800	51,600	2,000	53,600
7	16,900	9,000	53,200	4,000	57,200	185,800	16,000	201,800
8	3,800	2,000	50,200	21,500	71,700	194,800	86,000	280,800
9	3,800	2,000	5,400	15,000	20,400	15,600	60,000	75,600
Total	**68,300**	**36,300**	**211,400**	**73,600**	**285,000**	**736,700**	**294,400**	**1,031,100**

Notes:

(1) Based on the gravity sewer lengths for Sewer Layout Alternative 1, presented in Section 6.

(2) Calculated as pipe length (in miles) x pipe diameter (in inches) x 350 gpd/im.

(3) Maximum month value, including residential and commerical flows and infiltration.

(4) Calculated as 4 times the average daily sanitary flow plus infiltration.

The "Bowl", which is defined as the surface area that drains towards Lake Wequaquet, Long Pond, Bearse Pond, and Shallow Pond, and extends beyond the AOC, was considered in the determination of projected future wastewater flows. Although sewer service is not currently planned for the Bowl, it is anticipated that if future sewer service is provided to the Bowl that the wastewater from this area would flow into the new sewers that are proposed in the AOC. As such, the new sewers proposed within the AOC have been sized to accommodate wastewater flow from the Bowl and the AOC, where possible. Low pressure sewers are designed to accommodate a specific flow range and, in some cases, can not be sized to accommodate both current and future flow conditions.

The population estimates are based on house counts and an average of 2.5 people per house, similar to the methodology used to determine the current wastewater flows. House counts for the three categories listed above are presented in table 4-3.

Table 4-3
Future Residential House Counts & Population

Category	House Count	Population
Current – AOC & Adjacent to Proposed Sewers	1,149	2,884
Future - AOC	166	415
Bowl (current and future)	671	1,678
Total	**1,986**	**4,977**

The projected future study area population at full build-out has been estimated as 4,977 people by adding the current population estimate of 2,884 people to the population projected in the areas of potential future development in the AOC of 415 people and the Bowl of 1,678 people, as shown in Table 4-3.

The projected future study area population was used to project the future maximum month average daily sanitary flow that would be generated in the study area. The future average daily residential sanitary flow was estimated as approximately 358,300 gallons per day (gpd) by multiplying the projected future population by 72 gallons per person per day.

Although no new businesses or industries are projected for the study area, there are 19 existing commercial buildings within the Bowl, which have been included in the future flow projection. A summary of the maximum month commercial wastewater flows is presented in Table 4-4.

Table 4-4
Maximum Month Average Daily Commercial Sanitary Flows

Facility Type	Current Wastewater Flows (gpd)	Future Wastewater Flows (gpd)	Total Wastewater Flows (gpd)
I	4,000	16,300	20,300
II	26,000	4,500	30,500
III	11,000	0	11,000
Total	**41,000**	**20,800**	**61,800**

In total, the projected future maximum month average daily sanitary flow was calculated as 420,100 gpd by summing the residential and commercial flow components. The projected future peak sanitary flow was estimated as approximately 1,680,400 gpd by multiplying the average daily sanitary flow by the peaking factor of 4.0, similar to the approach used to calculate current peak sanitary flow.

If new sewers are constructed to serve the study area, some infiltration of groundwater into the sewers can be expected, as discussed under the description of current conditions. The study area average and peak projected future wastewater flows were estimated as 480,600 gpd and 1,740,900 gpd, respectively, by adding the projected sewer infiltration of 60,500 gpd to the sanitary flow projections noted above. This infiltration rate is based on a projected future total length of gravity sewers of 114,400 linear feet.

The average and peak projected future wastewater flows were determined for each of the study sub-areas using the approach described above. These flow rates are presented in Table 4-5.

4.3 CAPE COD COMMUNITY COLLEGE

4.3.1 Current Conditions

An evaluation of wastewater flows at Cape Cod Community College (CCCC) was performed in the 1996 Draft Phase III Facilities Plan, as is discussed in Section 2. In the Phase III report, the sanitary flows from the college were projected using water usage data from January 1991 to June 1996. Water usage was assumed to equal sanitary flow at the college because the college was not watering athletic fields and had minimal non-sanitary water use.

The Phase III report shows that the daily water usage ranged from 6,000 gpd to 16,600 gpd in the spring semester (12,100 gpd average) and from 2,000 gpd to 10,500 gpd in

Table 4-5
Summary of Projected Future Wastewater Flows at Full Build-Out (AOC and Bowl)
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

Sub-Area	Gravity Pipe Length (lf) [1]	Infiltration (gpd) [2]	Average Wastewater Flow (gpd) [3]			Peak Wastewater Flow (gpd) [4]		
			Current	Future [5]	Total	Current	Future [5]	Total
1	11,200	5,900	22,300	25,000	47,300	78,400	93,100	171,500
2	9,500	5,000	18,800	5,400	24,200	63,500	18,300	81,800
3	16,300	8,600	28,500	19,000	47,500	96,600	67,600	164,200
4	14,500	7,700	30,900	35,700	66,600	111,600	131,700	243,300
5	18,500	9,800	19,400	46,400	65,800	69,200	164,600	233,800
6	10,000	5,300	15,800	23,500	39,300	53,600	87,700	141,300
7	18,900	10,000	57,200	12,000	69,200	201,800	45,000	246,800
8	4,400	2,300	71,700	11,500	83,200	280,800	45,100	325,900
9	11,100	5,900	20,400	17,100	37,500	75,600	56,700	132,300
Total	**114,400**	**60,500**	**285,000**	**195,600**	**480,600**	**1,031,100**	**709,800**	**1,740,900**

Notes:

(1) Based on the gravity sewer lengths projected for full-build-out and Sewer Layout Alternative 1, presented in Section 6.

(2) Calculated as pipe length (in miles) x pipe diameter (in inches) x 350 gpd/im.

(3) Maximum month value, including residential and commerical flows and infiltration.

(4) Calculated as 4 times the average daily sanitary flow plus infiltration.

(5) Future wastewater flows consider infilling within the AOC and current and new houses within the Bowl.

the summer semester (5,100 gpd average). However, the implementation of water conservation measures was underway during the CCCC evaluation and these measures were expected to reduce daily flows by approximately 4,000 gpd.

Recent discussions with officials from the college and limited flow data provided in a 1999 study of sewage disposal at the college indicate that water conservation measures have been effective in reducing water use at the school. Current spring semester average daily water usage was reported to be in the range of 7,000 to 10,000 gpd and 1999 summer semester water usage was reported to be in the range of 3,000 to 5,000 gpd. As such, we have used average daily spring and summer semester wastewater flows of 10,000 gpd and 4,000 gpd, respectively, for the purposes of this evaluation.

The 1996 college population was presented in the Phase III report based on enrollment information provided by the college. Approximately 3,500 students were enrolled during the spring semester and 1,200 students were enrolled in the summer semester in 1996. In addition, there were approximately 450 spring staff and 350 summer staff at the college. The spring 1999 student enrollment was reported to have increased approximately 9% from the 1996 values while the summer 1999 student enrollment was reported to have increased approximately 17% from the 1996 values, as shown in Table 4-6. The 1999 staff levels were unchanged from those presented in the Phase III report.

Table 4-6
Cape Cod Community College 1999 Population

Season	Student Population	Staff Population	Total Population
Spring	3,800	450	4,250
Summer	1,400	350	1,750

We estimate 1999 average per capita spring and summer sanitary flow rates of 2.4 gpd (10,000 gpd/4,250 people) and 2.3 gpd (4,000 gpd/1,750 people), respectively. These values reflect the water conservation measures performed since the 1996 report was prepared.

We calculate the current peak sanitary flow as 56,000 gpd by multiplying the average daily sanitary flow of 10,000 gpd by the more conservative peaking factor determined from TR-16 of 5.6. Based on a estimated collection system length of 2,000 linear feet, a pipe diameter of 8 inches, and an infiltration rate of 350 gpd/im, the college collection system infiltration is estimated as approximately 1,100 gpd. The average wastewater flow is calculated as approximately 11,100 gpd and the peak wastewater flow is calculated as approximately 57,100 gpd by adding the estimated infiltration rate to the average and peak sanitary flows.

4.3.2 Future Conditions

Future growth at the college was projected in the 1996 Phase III report, based on the following:

- A student population growth of 5%/year over the 20-year planning period
- A staff population growth of 10% over the 20-year planning period
- The construction of a Technology Center, which would increase support staff by 2% and faculty by one person

Note that the annual student population growth from 1996 to 1999 is approximately 3% for the spring semester and 5-1/2% for the summer semester. For the purposes of this evaluation, we have used the population growth rate of 5% presented in the 1996 Phase III report to estimate future student population, based on the 1999 population data. In addition, we have considered a 20-year planning period from the date of this evaluation (2003). The projected Year 2023 college population is presented in Table 4-7.

Table 4-7
Cape Cod Community College Year 2023 Population

Season	Future Student Population	Future Staff Population	Future Total Population
Spring	12,255	505	12,760
Summer	4,515	393	4,908

Using the projected future spring semester population of 12,760 people and the average per capita flow rate of 2.4 gpd determined from 1999 flow data, the future average daily sanitary flow is calculated as approximately 30,600 gpd (2.4 x 12,760). We calculate the peak sanitary flow as 171,400 gpd by multiplying the average daily sanitary flow of 30,600 gpd by the more conservative peaking factor determined from TR-16 of 5.6, similar to the calculation for determining current peak flows.

As was noted in the previous report section, the college collection system infiltration rate is estimated as approximately 1,100 gpd. The future average wastewater flow is calculated as approximately 31,700 gpd and the future peak wastewater flow is calculated as approximately 172,500 gpd by adding the infiltration rate to the average and peak sanitary flows.

The college's engineering consultant for the design of their wastewater pumping facility has indicated that the pumps have been sized for a flow rate of 120 gpm (172,800 gpd), which closely matches the peak flow estimate developed in this evaluation.

5.1 GENERAL

A total of five connection points to the existing sewerage system were evaluated to determine the feasibility of sending wastewater flow to them from the Area of Concern (AOC) and the Cape Cod Community College. The surplus hydraulic capacity downstream of each connection point was reviewed by comparing full-pipe capacities and pump station design capacities to the estimated wastewater flows currently conveyed by these sewers and pump stations.

Full-pipe capacities were estimated using the Manning Equation, which is commonly used to calculate gravity pipe flow from pipe diameter, slope and internal surface roughness. Record plans provided by the Town were used to obtain information on pipe diameter and slope. The pipe roughness was assumed to be 0.013, which is a conservative value commonly used for this type of evaluation.

Current wastewater flows to the existing sewers downstream of the potential connection points were estimated using the approach described in Section 4. Residential flow rates were determined based on house counts and the average wastewater flow/house of 180 gpd (72 gpcd x 2.5 people/house) established in Section 4 while commercial flow rates were estimated using water usage data and a seasonal peaking factor was applied. Peak sanitary flows were estimated as 4 times the average daily sanitary flow estimates, similar to the approach used to estimate peak wastewater flow within the AOC. Infiltration was estimated based on sewer diameter and length and an assumed infiltration rate of 1,000 gpd/im. This infiltration rate is higher than that projected for new sewers of 350 gpd/im and reflects that the older pipes in the system, especially the AC pipes, typically experience more infiltration than new PVC sewers. The infiltration estimates were added to the peak sanitary flow values in order to calculate the peak wastewater flows.

The five connection points considered are listed below and are shown in Figure 5-1:

1. Old Strawberry Hill Road
2. Route 28
3. West Main Street
4. Route 132
5. Freezer Road pump station force main

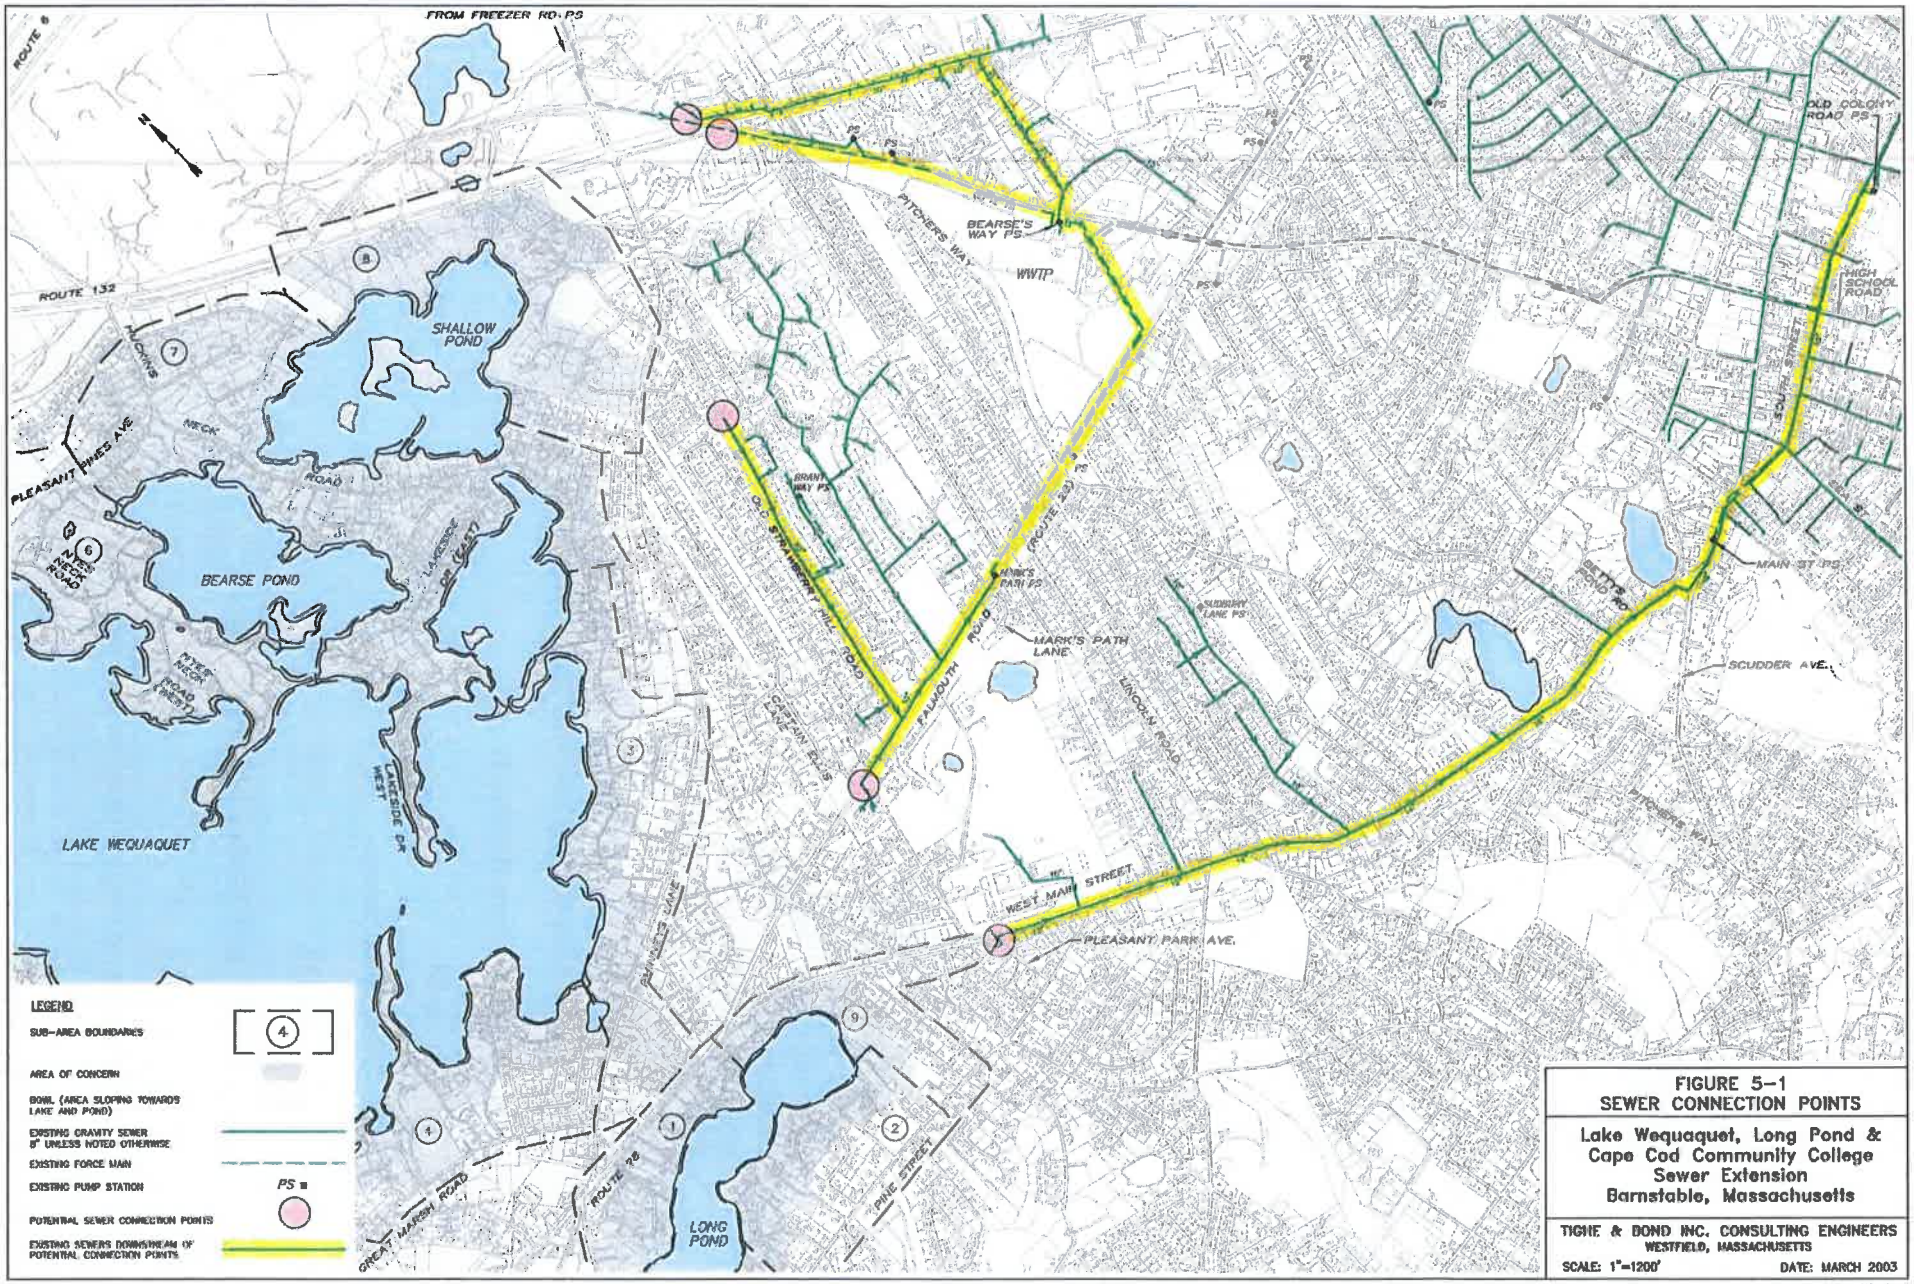

FIGURE 5-1

TIGHE & BOND INC. CONSULTING ENGINEERS
WESTFIELD, MASSACHUSETTS

SCALE: 1"=1200' DATE: MARCH 2003

5.2 OLD STRAWBERRY HILL ROAD

Connection to the Old Strawberry Hill Road sewer was considered in this evaluation because it is only 900 feet east of the northeastern section of the AOC, near Phinney's Lane. This sewer was also identified as a potential connection point in the 1987 Phase II facilities plan report.

The Old Strawberry Hill Road gravity sewer consists of 10-inch diameter PVC pipe and extends from Centerboard Lane to Route 28. The hydraulic capacity of this sewer was calculated as 0.75 mgd. In comparison, the estimated current peak wastewater flow was calculated as 0.06 mgd. As such, the surplus hydraulic capacity was calculated as 0.69 mgd (0.75 mgd - 0.06 mgd). However, it is important to note that wastewater flow from the Old Strawberry Hill Road sewer is conveyed to the Route 28 sewer. As such, the surplus capacity of the Route 28 sewer must also be considered in evaluating this potential wastewater connection point.

5.3 ROUTE 28

Connection to the Route 28 sewer was considered in this evaluation because it is only 2,000 feet east of the AOC. This sewer is in the vicinity of the southeastern section of Lake Wequaquet and the northeastern section of Long Pond. The Route 28 sewer was also identified as a potential connection point in the 1987 Phase II facilities plan report.

The Route 28 gravity sewer extends from Captain Ellis Lane to Mark's Path Lane. Wastewater flow collected by this gravity sewer is conveyed to the Marks' Path pump station, where it is subsequently pumped through a 6-inch force main on Route 28 to the wastewater treatment plant (WWTP). The gravity sewer is 8-inch diameter from Captain Ellis Lane to Old Strawberry Hill Road and is 10-inch diameter from Old Strawberry Hill Road to the Marks' Path pump station.

The hydraulic capacity of the Route 28 gravity sewer ranges from 0.50 mgd to 2.10 mgd and the Mark's Path pump station has a design capacity of 0.43 mgd. In comparison, the estimated current peak wastewater flow entering the Mark's Path pump station is 0.30 mgd. The Route 28 sewer has been divided into several sections for the purposes of comparing sewer capacity to estimated peak wastewater flow and calculating surplus hydraulic capacity, as shown in Table 5-1.

Table 5-1
Existing Wastewater Flows vs. Sewer Capacity – Route 28

Sewer Section/Pump Station	Sewer Diameter (inches)	Min. Pipe Slope (%)	Peak Wastewater Flow (mgd) (1)	Sewer Capacity (mgd) (2)	Surplus Capacity (mgd) (3)
End to Old Strawberry Hill Rd.	8	0.40	0.07	0.50	0.46
Old Strawberry Hill Rd. to Whitehall Way	10	0.28	0.14	0.75	0.61
Whitehall Way to pump station	10	0.14	0.30	0.53	0.23
Mark's Path pump station	---	---	0.30	0.43	0.13

Notes:
(1) Estimated based on residential house counts and commercial water use data.
(2) Based on lowest capacity reach within sewer section under review.
(3) Calculated by subtracting peak wastewater flow from sewer capacity.

The capacity of the Mark's Path pump station currently limits the capacity available to accept wastewater flow from the AOC to 0.13 mgd. Note that the Mark's Path pump station also limits the amount of wastewater flow that can be accepted from the upstream Old Strawberry Hill Road connection point.

AOC Sub-Areas 1, 2, 3, 4 and 9, shown in Figure 5-1, are closest to the Route 28 sewer and, as such, the projected flows from these sub-areas were compared in Table 5-2 to the surplus capacities described above in Table 5-1.

Table 5-2
AOC Peak Wastewater Flows vs. Route 28 Sewer Surplus Capacity

AOC Sub-Area	Estimated Current Peak Wastewater Flow (mgd)	Surplus Capacity (mgd)	Projected Future Peak Wastewater Flow (mgd)	Surplus Capacity (mgd)
1	0.08	0.13	0.17	0.13
2	0.06	0.13	0.08	0.13
9	0.08	0.13	0.13	0.13
Subtotal	**0.22**	**0.13**	**0.38**	**0.13**
3	0.10	0.13	0.16	0.13
4	0.11	0.13	0.24	0.13
Subtotal	**0.21**	**0.13**	**0.40**	**0.13**
Total	**0.43**	**0.13**	**0.78**	**0.13**

This connection point would be most effectively utilized by:

1. accepting the wastewater flow from the Long Pond area and the southern portion of Lake Wequaquet (Sub-Areas 1, 2, 3, 4 and 9);

2. accepting the wastewater flow from the Long Pond area only (Sub-Areas 1, 2 and 9); or

3. accepting the wastewater flow from the southern portion of Lake Wequaquet only (Sub-Areas 3 and 4)

Table 5-2 shows that this connection point does not have sufficient surplus capacity to serve any of the AOC sections described above. In fact, this connection point only has surplus capacity to accommodate the projected peak wastewater flow from Sub-Area 2 alone. In order to accommodate the current or future wastewater flows from either the Long Pond area or the southern portion of Lake Wequaquet, improvements to the Mark's Path pump station would be required. In addition, sewer improvements from Whitehall Way to the pump station would also be required in order to accommodate the projected peak future wastewater flows from these areas.

5.4 WEST MAIN STREET

Connection to the West Main Street sewer was considered in this evaluation because it is approximately 1,500 feet east of the AOC surrounding Long Pond. This sewer was also identified as a potential connection point in the 1987 Phase II facilities plan report.

The West Main Street gravity sewer extends from Pleasant Park Avenue to Scudder Avenue, and then continues on Main Street, discharging wastewater flow into the Main Street pump station. Wastewater flow is then discharged from the Main Street pump station into a gravity sewer on South Street, which conveys the wastewater flow to the Old Colony Road pump station. The West Main Street sewer is 12-inch diameter from its upstream end to Lincoln Road, 14-inch diameter from Lincoln Road to Pitcher's Way, 16-inch diameter from Pitcher's Way to Bettys Pond Road, and 18-inch diameter from Bettys Pond Road to the Main Street pump station. Wastewater flow from the Main Street pump station is discharged through an 8-inch force main to an 8-inch gravity sewer on South Street at Sea Street. The South Street gravity sewer is 8-inch diameter for approximately 8 feet, then changes to a 10-inch diameter sewer. The South Street gravity sewer is 10-inch diameter from Sea Street to High School Road, 12-inch diameter from High School Road to Ocean Street, 15-inch diameter from Ocean Street to approximately 250 feet east of Ocean Street, and 21-inch diameter from approximately 250 feet east of Ocean Street to the Old Colony Road pump station.

The hydraulic capacity of the West Main Street, Main Street and South Street gravity sewers range from 0.78 mgd to 12.57 mgd and the Main Street pump station has a design capacity of 0.70 mgd. The hydraulic capacity of the gravity sewers was calculated in this evaluation as the largest quantity of flow that the pipe can convey (full pipe flow) without flowing under pressure. In comparison, the estimated current peak wastewater flow at the downstream end is 1.33 mgd. The West Main Street/Main Street/South Street sewer has been divided into several sections for the purposes of comparing sewer capacity to estimated peak wastewater flow and calculating surplus hydraulic capacity, as shown in Table 5-3.

The Main Street pump station and the downstream sewer sections on South Street, from the pump station to Ocean Street, do not have any surplus hydraulic capacity. As such, sewerage system improvements would be necessary in order to use this potential connection point from the AOC to the existing sewerage system. The 1987 Phase II facilities plan report noted that there are currently hydraulic restrictions on South Street within the 10-inch and 12-inch sewer sections, as is confirmed by this evaluation.

However, note that there does appear to be sufficient surplus capacity within the sewers upstream of the Main Street pump station to accommodate the estimated current peak wastewater flows from Sub-Areas 1, 2 and 9, as shown in Table 5-4. The surplus hydraulic capacity value shown in Table 5-4 is the lowest surplus capacity value calculated within the pipe sections upstream of the pump station developed in Table 5-3. In addition, there may be sufficient surplus capacity within the sewers upstream of the Main Street pump station to accommodate the projected future peak wastewater flow from these sub-areas. The word "may" is emphasized because the projected future peak wastewater flow value is only slightly higher than the estimated surplus capacity. Because significant growth has been estimated in Sub-Areas 1 and 9, which may or may not occur, and there are expected to be opportunities to convey wastewater flow from these potential growth areas to other connection points, we recommend that this connection point be considered.

Table 5-4

AOC Peak Wastewater Flows vs. West Main Street Sewer Surplus Capacity

AOC Sub-Area	Estimated Current Peak Wastewater Flow (mgd)	Surplus Capacity (mgd)	Projected Future Peak Wastewater Flow (mgd)	Surplus Capacity (mgd)
1	0.08	0.34	0.17	0.34
2	0.06	0.34	0.08	0.34
9	0.08	0.34	0.13	0.34
Total	**0.22**	**0.34**	**0.38**	**0.34**

Existing Wastewater Flows vs. Sewer Capacity - West Main St./Main St./South St.
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

Sewer Section/Pump Station	Sewer Diameter (inches)	Min. Pipe Slope (%)	Peak Wastewater Flow (mgd) [1]	Sewer Capacity (mgd) [2]	Surplus Capacity (mgd) [3]
West Main St. (end to Seaboard Ln.)	12	0.19	0.19	1.01	0.82
West Main St. (Seaboard-Lafrance)	12/14	0.22	0.48	1.08	0.60
West Main St. (LaFrance-Pitcher's way)	14	0.10	0.76	1.10	0.34
West Main St. (Pitcher's way-Pine Grove Ave.)	16	0.11	0.88	1.65	0.77
West Main St. (Pine Grove-North St.)	16/18	0.14 (18 inch)	0.96	2.55	1.59
Main St. (North St.- Pump Station)	18	0.05	1.08	1.52	0.44
Main St. Pump Station	---	---	1.37	0.70	None
South St. (Sea St.-Chase St.)	8/10	0.30 (10 inch)	1.11 [4]	0.78	None
South St.(Chase St.-Pine Ave.)	10	0.30	1.15 [4]	0.78	None
South St.(Pine Ave-High School Rd.)	10	0.30	1.18 [4]	0.78	None
South St. (High School Road-Pearl St.)	12	0.21	1.58 [4]	1.06	None
South St. (Pearl St.-Ocean St.)	12	0.21	1.66 [4]	1.06	None
South St. (Ocean St. to Old Colony Rd. Pump Station)	15/21	0.15 (15 inch)	1.69 [4]	1.62	None

Notes:

(1) Estimated based on residential house counts and commercial water use data.

(2) Based on lowest capacity reach within sewer section under review.

(3) Calculated by subtracting peak wastewater flow from sewer capacity.

(4) Includes a pumped flow of 0.70 mgd from the Main Street pump station and a pumped flow of 0.29 mgd from the Sea Street pump station.

No surplus capacity available

Upgrading the pump station and redirecting the pump station force main to the nearby Old Colony Road pump station force main was considered in this evaluation in order to utilize the surplus capacity upstream of the Main Street pump station. These upgrades are discussed in greater detail in Section 6.

5.5 ROUTE 132

Connection to the Route 132 sewer was considered in this evaluation because it is approximately 1,800 feet east of the AOC. This sewer extends from Old Route 132 to Enterprise Road along Route 132 and then from Route 132 to the WWTP on Enterprise Road. The Route 132 sewer is 8-inch and 10-inch in diameter and the Enterprise Road sewer is 21-inch in diameter. The 21-inch Enterprise Road sewer discharges into the Bearses Way pump station, which is located at the WWTP. The Bearses Way pump station pumps the wastewater flow to the plant headworks for subsequent treatment.

The hydraulic capacity of the Route 132 and Enterprise Road gravity sewers range from 0.54 mgd to 5.71 mgd. In comparison, the estimated current peak wastewater flow at the downstream end is 1.38 mgd. The Route 132 and Enterprise Road sewer capacities, as well as the capacity of the Bearses Way pump station, have been compared to the estimated peak wastewater flows in Table 5-5.

Table 5-5

Existing Wastewater Flows vs. Sewer Capacity – Route 132

Sewer Section/Pump Station	Sewer Diameter (inches)	Min. Pipe Slope (%)	Peak Wastewater Flow (mgd) [1]	Sewer Capacity (mgd) [2]	Surplus Capacity (mgd) [3]
Route 132	8/10	0.48 (8 inch)	0.71	0.54	None
Enterprise Road	21	0.12	1.38	3.56	2.18
Bearses Way Pump Station	---	---	1.38	1.06	None

Notes:

(1) Estimated based on residential house counts and commercial water use data.

(2) Based on lowest capacity reach within sewer section under review.

(3) Calculated by subtracting peak wastewater flow from sewer capacity.

The Route 132 gravity sewers and the Bearses Way pump station do not have any surplus hydraulic capacity. As such, sewerage system improvements would be necessary in order to use this potential connection point from the AOC to the existing sewerage system.

5.6 FREEZER ROAD PUMP STATION FORCE MAIN

Connection to the Freezer Road pump station force main was considered in this evaluation because it is approximately 1,800 feet east of the AOC. There are two 12-inch force mains that extend from the Freezer Road pump station located in North Barnstable, along Phinney's Lane, Old Route 132, and Bearses Way, to the WWTP. Currently, only one of the two force mains is utilized. However, Town officials have indicated that the unused force main may be used in the future to convey treated wastewater to a new groundwater recharge site in North Barnstable.

We estimate that each Freezer Road pump station 12-inch force main has a maximum capacity of approximately 4.0 mgd, based on a peak pipe velocity of 8.0 feet per second. This approach provides an upper-end value that can be compared to projected pipe flows. However, the determination of force main capacity is typically more complex since the quantity of flow that the force main conveys has a direct impact on the operation of the upstream pumps. In comparison, the design flow of the Freezer Road pump station is 1.08 mgd and the current velocity through one main is 2.13 fps.

The Freezer Road pump station force mains appear to have a significant amount of surplus hydraulic capacity and connection to it has been considered in developing sewer layout alternatives, as is detailed in Section 6.

5.7 CONCLUSIONS

The Freezer Road pump station force mains appear to have the greatest amount of surplus hydraulic capacity of the connection points considered. The sewer layouts developed in Section 6 have utilized this connection point. In addition, the West Main Street connection point has been considered in Section 6 because there appears to be sufficient surplus capacity upstream of the Main Street pump station to accommodate wastewater flows from the Long Pond area. As noted previously, this connection point will require improvements to the Main Street pump station and the existing sewer system in this area.

The remaining potential connection points considered on Old Strawberry Hill Road, Route 28, and Route 132 would require significant pipe and pump station upgrades to the existing sewerage system and, as such, are not recommended.

6.1 GENERAL

Sewer layout alternatives to serve the Area of Concern (AOC) and the Cape Cod Community College (CCCC) were developed as part of this evaluation with the goals of minimizing construction costs, life cycle costs, environmental impacts, and neighborhood impacts, while providing a flexible and reliable sewer collection system. In order to accomplish the above goals, three sewer collection system technologies were considered:

- Conventional gravity sewers and pump stations
- Low pressure sewers and grinder pumps
- Vacuum sewers and vacuum stations

Both current and projected future conditions were considered in developing each of the sewer alternatives so that both the short-term and long-term sewage collection needs of the area can be accommodated, to the extent possible, with the new sewers proposed. Future conditions are based on full build-out within the AOC and potential expansion of the AOC collection system to provide sewer service to the surrounding areas (the Bowl).

Four sewer layout alternatives were determined to be most appropriate for conveying wastewater flow from the AOC and the Cape Cod Community College to the existing sewerage system and consist of various combinations of the technologies listed above. Other alternatives were eliminated from consideration during a preliminary screening process.

For each of the four sewer extension alternatives, detailed construction cost estimates have been developed and are presented in Section 9. In addition, an evaluation of non-monetary criteria, such as neighborhood impacts and environmental impacts, has been performed for each alternative and is also presented in Section 9.

The three sewer collection system technologies are generally described in the paragraphs below followed by a detailed description of each of the four sewer extension alternatives.

6.1.1 Gravity Sewers and Pump Stations

Gravity sewer systems are the most prevalent of the collection system technologies considered and modern gravity sewer construction has been implemented for well over 100 years. Gravity sewers are installed at a constant downward gradient, with a sufficient slope to prevent solids from settling in the pipe.

For the gravity sewers, the following preliminary design criteria were used in this evaluation:

- A minimum pipe diameter of 8 inches, as required by the MADEP for public sewers and in accordance with TR-16 guidelines.
- A minimum installation depth of 8 feet, to serve the building first floor levels within the project area (it may be possible to reduce this depth during design in some areas).
- A maximum installation depth of 25 feet below grade.
- A minimum slope of 4 feet per 1,000 feet (this is the minimum slope to maintain sufficient velocity prevent solids deposition in an 8-inch diameter sewer).
- A maximum flow depth of 80% of the pipe diameter at peak flow (under full build-out conditions).

In most cases, homes along a gravity collector sewer connect into it using gravity house service pipes. However, houses below the street elevation may need grinder pumps to convey the flow from the house to the collector sewer. The houses along gravity collector sewers that would require grinder pumps were identified for each of the four alternatives, based on the difference in grades between the house and the street, the distance from the house to the street, the proposed collector sewer depth, and a minimum house service slope of 1/4-inch/foot. The need for grinder pumps along gravity sewers will be confirmed during design based on more detailed topographic data, the finalized sewer layout, and data provided by the homeowners.

The construction costs associated with the installation of gravity sewers depend upon local topography. In areas where the topography is constantly increasing or decreasing, the sewer can be installed at the minimum depth required to serve the houses along the sewer. However, where there is rolling, hilly terrain, deep excavation and/or pump stations may be needed, which can significantly increase construction costs. This is especially true in areas where ledge will be encountered or where there are high groundwater levels.

Gravity sewer construction is most cost-effective in densely developed areas since the cost of the main line pipe is relatively high while the cost of the service connections is relatively low.

Gravity sewer advantages include:

- Little maintenance, although maintenance needs increase if pump stations are proposed.
- Can be easily designed to accommodate future growth and system expansion.
- Low potential for odors, although odor potential increases if pump stations are proposed.
- Reliable, since there is no reliance on mechanical equipment or power. If pump stations are needed, standby generators would be provided to supply power in the event of power loss and standby pumps would be provided to ensure continuous, uninterrupted operation in the event of a pump failure.

Gravity sewer disadvantages include:

- Can require deep excavations or pump stations, depending on topography, which increase construction cost.
- Susceptible to groundwater infiltration.

Because pump stations are proposed in some areas within the AOC, under each of the alternatives, to reduce the amount of deep sewer trench excavations that would otherwise be required, four pump station types were considered for this evaluation:

- Grinder pump stations
- Submersible pump stations
- Suction lift (self-priming) pump stations
- Wetwell/drywell pump stations

The grinder pump stations are prefabricated, package units while the submersible, suction lift, and wetwell/drywell pumping facilities can either be prefabricated, package facilities or built-in-place facilities, depending on community preference and service area size. Built-in-place facilities are often more appropriate and cost-effective for large service areas.

Duplex grinder pump stations were considered for this evaluation and are considered appropriate where the anticipated wastewater flows are relatively small (up to an average daily flow of 6,000 gpd). These facilities consist of two grinder pumps (semi-positive displacement or submersible) in a below-grade prefabricated polyethylene or fiberglass

reinforced plastic wetwell, high water level instrumentation, and pump controls housed in an above-grade panel. The grinder pump facilities are package pump stations, similar to the single-home grinder pump units described in the next report section. Normally, facilities of this size do not require standby power but can be provided with a connection for a portable generator. For this evaluation, we have assumed that a portable generator connection would be provided. The prefabricated grinder pump facilities provide a low cost pump station option but are only appropriate for relatively small service areas.

Submersible pump stations were also considered for this evaluation. These facilities offer the advantage of being relatively low in cost and typically have a less significant aesthetic impact than suction lift or wetwell/drywell pump stations since most of the facility components, with the exception of the control panel and a generator, if needed, would be located below grade. A submersible pump station typically consists of two or more submersible pumps, a concrete wetwell, water level monitoring instrumentation, and pump controls. The pumps at these facilities must be removed and disassembled for inspection and maintenance, requiring a hoist or crane. The submersible pumping facilities, which can accommodate a wide range of flows, are often package facilities where the pumps, instrumentation, and controls are provided as an integrated system. The submersible pump stations can be provided with or without a building, depending on owner preferences, and, for the larger facilities, are typically provided with standby power. If standby power is needed and a building is planned, the generator can be housed within the building, along with the pumps, instrumentation, and controls. Otherwise, the standby generator would be provided within a weather-proof enclosure. A separate valve chamber is often constructed just downstream of the submersible pump station to facilitate maintenance of the valves on the discharge side of the pump. A typical submersible pump station is shown in Figure 6-1.

Suction lift pump stations, which can accommodate a similar flow range to the submersible pumping facilities, were also considered. The suction lift pump station components are similar to the submersible pump station components with the exception that the pumps would be located above the wetwell and at grade, if possible, to facilitate pump maintenance. Typical suction lift pumps have the capability to lift wastewater approximately 20 feet. If the wetwell operating levels are greater than 20 feet below grade, then either a different type of pump would be needed or the suction lift pumps would need to be installed below grade. The suction lift pump stations are often package-type facilities, similar to the submersible pumping facilities. A building or above-grade enclosure can be provided, similar to the submersible pumping facilities, to house pump controls, instrumentation, and a standby generator, if needed. Otherwise, the pumps can be located in a below-grade drywell with the controls located in an above-grade panel. However, under this arrangement the drywell would be considered a confined space and appropriate safety precautions would need to be taken by Town personnel when working on the pumps. Suction lift pump stations are generally preferred by the Town over

submersible pumping facilities. A typical suction lift pump station is shown in Figure 6-2.

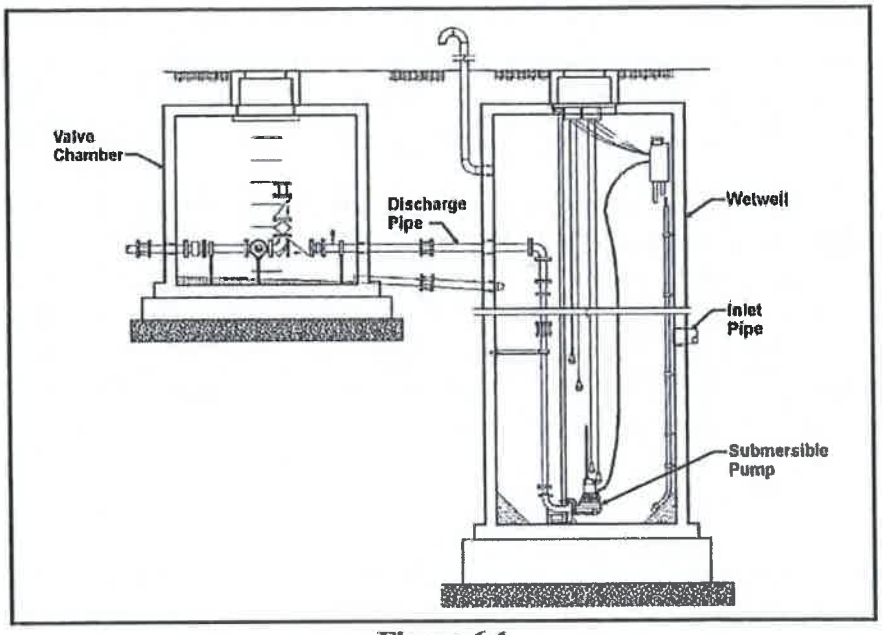

Figure 6-1
Typical Submersible Pump Station

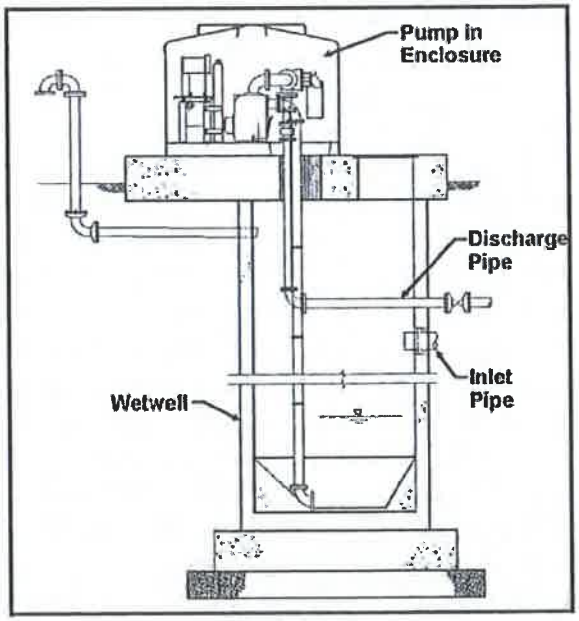

Figure 6-2
Typical Suction Lift Pump Station

Wetwell/drywell pumping stations were considered in this evaluation and consist of a wetwell, a drywell where the pumps are located, solids-handling pumps and pump controls/instrumentation. These facilities are typically more expensive than the submersible or suction lift facilities because of the added cost to construct the below-grade drywell. In a typical wetwell/drywell pump station arrangement, there are two levels. The pumps and piping would be located in the drywell, which would be located adjacent to the wetwell and at the bottom level of the facility. The station controls, instrumentation, and standby generator would be located at the top level of the facility. The drywell would be provided with appropriate lighting and ventilation to avoid confined space safety concerns. Pumps are more easily maintained at these facilities. A typical wetwell/drywell pump station is shown in Figure 6-3.

A summary of the advantages and disadvantages of the pump stations types considered is presented in Table 6-1.

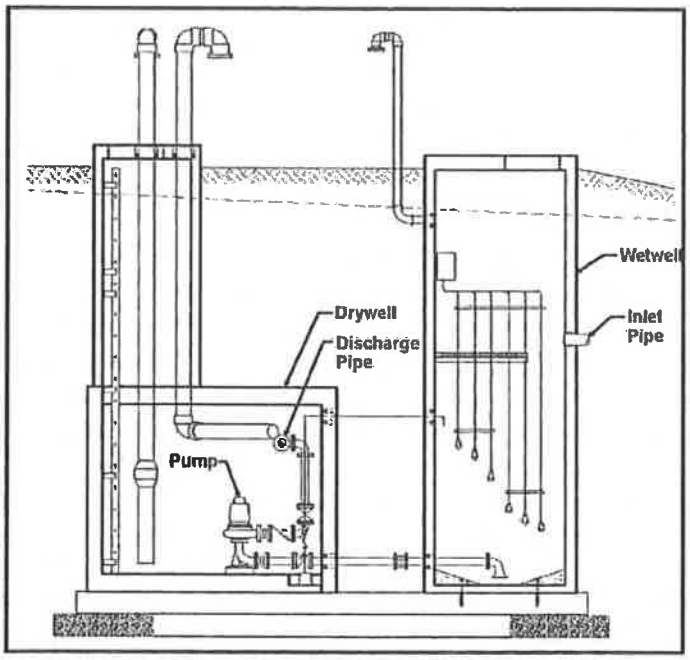

Figure 6-3
Typical Wetwell/Drywell Pump Station

Table 6-1

Advantages and Disadvantages of the Pump Station Types Considered

Pump Station Type	Advantages	Disadvantages
Duplex grinder	• Lowest cost • Smallest aesthetic impact	• Can only accommodate small service areas
Submersible	• Relatively low cost • Small aesthetic impact • Small land area needed • Drywell is not needed	• More difficult to maintain pumps • Separate vault typically provided for discharge valves
Suction lift	• Relatively low cost • Relatively easy to access and maintain pumps • Drywell is not needed	• Less reliable than other pumps due to need for priming • Distance from the low wetwell level to the pumps is limited to approximately 20 feet
Wetwell/drywell	• Easiest to maintain pumps • Can accommodate the widest range of flows • Flooded suction pumps are more reliable	• Highest cost • Largest aesthetic impact • Largest land area needed

6.1.2 Low Pressure Sewers

Low pressure sewer systems have been constructed in the United States since the early 1970s and the use of this collection system technology has increased significantly over the past 10 years. In a low pressure sewer system, wastewater flows by gravity from the building(s) being served into a sump, where the wastewater is subsequently shredded and then pumped through a pressure pipe to a low pressure collector sewer. The low pressure collector sewer then discharges into a downstream gravity sewer or force main. Because the collector sewers are pressure pipes, they may be installed to more closely follow the existing topography, allowing excavation depths to be minimized. Typical operating pressures are less than 60 psi within the collector sewers.

Low pressure sewers are well-suited for areas with hilly, rolling terrain because the deep excavation and/or pump stations that would be required for gravity sewer systems can be avoided. In addition, low pressure sewers are generally more cost-effective in areas that are less densely developed since the cost of the main line pipe is relatively low while the cost of the service connections (which include grinder pumps) is relatively high.

Low pressure sewer piping is sized small enough to provide a velocity sufficient to assure that the pipe will be self-cleansing while large enough to avoid excessive headlosses that

would impact grinder pump operation. Because pipe velocity and headloss must be balanced, a low pressure system is sized for a specific flow range and can not as readily accommodate significant future expansion as can gravity sewer systems.

A typical residential home grinder pump would operate over a short duration (5± minutes) once or twice per day. As such, only a percentage of the total number of grinder pumps in a service area would be operating at the same time. A common approach used to determine the size of the low pressure sewers needed to serve the area is to assume that a certain percentage of the grinder pumps would be active. For example, E/One indicates that if there are 19-30 upstream grinder pumps, typically no more than 5 of these grinder pumps will be active at the same time.

One grinder pump unit would typically be installed at each home or business/commercial property. The grinder pump unit typically consists of a semi-positive displacement or centrifugal pump, a below-grade prefabricated wetwell (constructed of polyethylene or fiberglass reinforced plastic) to store wastewater flow from the house, high water level alarm instrumentation, and pump controls housed in an above-grade panel, as shown in Figure 6-4.

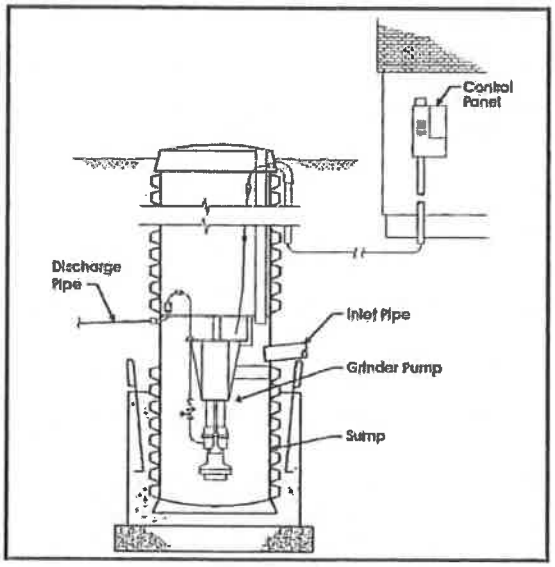

Figure 6-4
Typical Grinder Pump Unit (E/One Unit Shown)

Pump operation is normally initiated by a water level in the sump and a visual local high water alarm is normally provided. An audible alarm is also available and can be provided at each control panel. Remote monitoring of the grinder pumps can also be provided. Grinder pump monitoring information that can be collected locally and transmitted to a remote location include:

- Wastewater level in the sump
- Pump run time
- Number of pump activations
- Alarm status

In some communities that have installed low pressure sewers, the grinder pumps are owned, operated, and maintained by the individual homeowners, while in others, the community owns, operates, and maintains the grinder pumps. For the purposes of this evaluation, we have included the grinder pump costs in the alternatives cost estimates.

For the purposes of this evaluation, we have assumed that there will be one grinder pump for every home connected to a low pressure sewer. However, in some cases it may be possible and appropriate to serve two or more residential homes with a duplex grinder pump station. The feasibility and cost-effectiveness of serving multiple single-family homes with duplex grinder pump stations is a function of housing density in the neighborhood where this is being considered, land availability, and public acceptance. The feasibility and appropriateness of constructing duplex grinder pump stations will be evaluated during the design phase of the project. We have also assumed that each grinder pump will be provided with a connection for a portable generator that can be connected and engaged in the event of a power failure.

Low pressure sewer advantages include:

- Excavation depths can be shallow since the low pressure sewer can follow the existing topography.
- Collector sewer construction can proceed more quickly and with less disruption than gravity sewers as a result of the more shallow excavation depths.
- Smaller piping (typically ranging from 1-1/2-inch to 6-inch) can be used than is needed for gravity sewers because the grinder pumps shred the wastewater solids.
- Infiltration is not a concern since the wastewater is conveyed in a pressure pipe.

Low pressure sewer disadvantages include:

- Operation and maintenance costs are typically higher than for gravity systems since each building would have its own pump.
- Normally backup power is not provided in the event of a power failure. Sewage backups into house service lines could occur during a prolonged power outage.

This concern can be mitigated, to some extent, by providing portable generator connections on the grinder pumps.

- The wastewater retention time is marginally longer than is typically experienced in a well-designed gravity sewer system, which could lead to the formation of blockages and/or odors. Communities with seasonal flow variations are more susceptible to this problem.
- Exfiltration could occur if there are leaks or breaks in the pipe.
- Can accommodate less future growth.

6.1.3 Vacuum Sewers

Vacuum sewer systems have been constructed in the United States since the early 1970s, similar to the low pressure sewer systems, and there are over 200 vacuum sewer systems in place in 28 states. However, there is only one completed vacuum sewer system in New England, located in Barnstable, although a second system in Provincetown is expected to be completed this December. As such, we consider vacuum sewers to be a relatively new technology in this area.

In a vacuum sewer system, wastewater flows by gravity from the building(s) being served into a sump. When the wastewater reaches a preset level in the sump then a pneumatically actuated control valve opens, allowing the wastewater to be drawn out of the sump and into the vacuum collector sewer because of the pressure difference between the collector sewer and the atmospheric pressure in the sump. The wastewater in the vacuum collector sewer is conveyed further downstream each time a control valve is opened, until the wastewater flow eventually reaches the vacuum station. From the vacuum station, the wastewater is pumped into a gravity sewer or force main.

Similar to the low pressure sewers, the vacuum sewers may be installed to more closely follow the existing topography, allowing excavation depths to be minimized. However, for level or uphill pipe runs the vacuum sewers must be installed in a specific, saw-tooth configuration in order for the system to function as intended. Similar to the low pressure sewers, the vacuum sewers are generally more cost-effective in areas that are less densely developed since the cost of the main line pipe is relatively low while the cost of the service connections (which include the valve pits) is relatively high.

For the vacuum sewer system, a valve pit package would typically be installed at each home or business, although up to 4 homes can be served by one package. The valve pit package includes a control valve, a valve pit, and a control panel, as shown in Figure 6-5. The valve pit is split into two chambers: the lower chamber where wastewater from the home is stored and the upper section, which is completely sealed from the

lower section, where the valve is housed. The control valve requires no power and activates pneumatically based on pressure differential in the lower chamber caused by rising sewage level. This allows wastewater collected within the lower chamber to be drawn into the vacuum sewer in the street and subsequently to the downstream vacuum station.

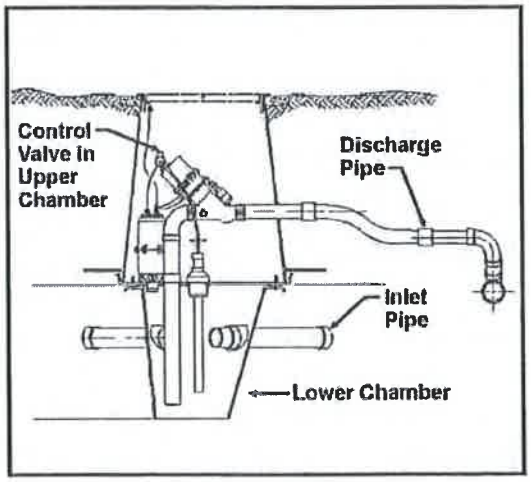

Figure 6-5
Typical Vacuum Valve Pit Package (AIRVAC unit shown)

Vacuum sewer advantages include:

- Excavation depths can be shallow since the vacuum sewers can generally follow the existing topography.
- Construction can proceed more quickly and with less disruption than gravity sewers as a result of the more shallow excavation depths.
- Smaller piping (typically ranging from 3-inch to 10-inch) can be used than is needed for gravity sewers.
- Infiltration is not a significant concern since the piping needs to be "tight" in order for the vacuum system to operate properly.
- Exfiltration is less of a concern.
- Low potential for odors within the piping system, although odors can occur and are a concern within the vacuum stations.

- The mechanical valve provided at each home would not be affected by a power outage. At the vacuum stations, standby generators would be provided to supply power in the event of power loss and standby pumps would be provided to ensure continuous, uninterrupted operation in the event of a power failure.

Vacuum sewer disadvantages include:

- Because a vacuum must be maintained in the system for it to operate properly, a pipe break will impact the entire system.
- Leaks in the system may be difficult to locate.
- Operation and maintenance costs are typically higher than for gravity systems since each building would have its own control valve.
- Vacuum sewer technology is relatively new in the New England area, which could result in higher construction costs than would be experienced in other areas where contractors are more familiar with the installation of these systems.

6.1.4 Odor Control

Because some long low pressure sewers and force mains will be constructed as part of this project, for each of the alternatives under consideration, hydrogen sulfide generation, which is a source of sewage odors, is a concern. Hydrogen sulfide odor is commonly characterized as smelling like rotten eggs. Hydrogen sulfide can form where anaerobic conditions exist, as is often found in long pressure pipes which flow full because of the long detention times. The release of hydrogen sulfide gas is also a concern because it could lead to the formation of sulfuric acid, which can deteriorate concrete manholes and wetwells. Significant hydrogen sulfide generation (and subsequently sulfuric acid) can also occur in gravity sewers with long wastewater detention times, although this is less common.

For the Barnstable project, facilities to provide hydrogen sulfide control are recommended. Hydrogen sulfide control is most often provided through chemical addition to oxidize the hydrogen sulfide or to inhibit its formation. Oxidizing chemical feed options include:

- Chlorine,
- hydrogen peroxide, and
- potassium permanganate.

Although oxidizing the hydrogen sulfide can be effective, oxidizing chemicals are not recommended because:

- They are more difficult and dangerous to handle because of their corrosive nature
- Storage of these corrosive chemicals near to the nearby surface water bodies is a concern
- They are generally more expensive than the inhibitors on the market

A commonly used inhibitor, calcium nitrate (commonly known as Bioxide), can be supplied in liquid form, is easily handled, does not freeze at the low temperatures experienced in the project area, an does not readily degrade. For the purposes of this evaluation, calcium nitrate has been selected as the preferred odor control chemical. However, other odor control chemicals will be reviewed in greater detail during design. Specific locations where odor control may be appropriate will be discussed under the description of each alternative.

A calcium nitrate feed system is typically provided as a package unit and consists of a chemical storage tank, a chemical feed pump, and chemical feed controls.

6.2 DESCRIPTION OF ALTERNATIVES

6.2.1 Alternative 1 – Gravity & LP Sewers, 8 Pump Stations

Alternative 1, shown in Figure 6-6, was developed to maximize the amount of gravity sewers while minimizing the number of conventional pump stations and low pressure sewers/grinder pumps within the AOC. Vacuum sewers were not considered as part of this alternative. This alternative is described in detail in the paragraphs that follow and is summarized in Table 6-2.

Alternative 1 includes:

- 125,500 feet (24± miles) of proposed sewers;
- 68,250 feet of gravity sewers (54% of total);
- 8 proposed pump stations and replacement of the Main Street pump station; and
- 361 grinder pumps.

Notes:

(1) Includes replacement of the Main Street pump station and diverting flow from the pump station to the Old Colony Road pump station force main.

6.2.1.1 Long Pond (Sub-Areas 1, 2 & 9)

Under Alternative 1, the wastewater flow from the Long Pond area would be conveyed easterly to the existing gravity sewer on West Main Street. The current peak wastewater flow from this area is approximately 0.22 mgd and the projected future peak wastewater flow, at full build-out and including sewer expansion into the Bowl, is 0.38 mgd. In comparison, the surplus capacity of the West Main Street and Main Street gravity sewers is estimated as approximately 0.34 mgd without any surcharging. As such, the existing West Main Street and Main Street gravity sewer sections have sufficient surplus capacity to accommodate current peak flows and may have sufficient capacity to accommodate the projected future peak flows, as discussed in Section 5. The word "may" is emphasized because the projected future peak flow is slightly higher than the surplus capacity available. Because significant growth has been estimated in Sub-Areas 1 and 9, which may or may not occur, and there are expected to be opportunities to convey wastewater flow from these potential growth areas to other connection points, we recommend that this nearby connection point, which is the most cost-effective, be used for Sub-Areas 1, 2 and 9. Additionally due to the depths of the existing sewers, minor surcharging (pressure flow) could be accommodated without negative impact. This would increase the carrying capacity of the sewers above the gravity flow limit noted above. Improvements to the Main Street pump station and its force main would be required in order to utilize this connection point.

Conveying the wastewater flow from the Long Pond area to the nearby Route 28 sewer was also considered. However, this connection point is not recommended because it has less surplus hydraulic capacity than the West Main Street connection (0.22 mgd) and would require the replacement of 1,000± feet of gravity sewer and the Mark's Path pump station. Another alternative considered was to convey the wastewater flow from the Long Pond area northerly to the Freezer Road pump station force main. This connection point is not recommended because it would result in a higher life cycle cost.

Sub-Area 1

Sub-Area 1 includes the portions of the AOC north, west, and southwest of Long Pond. Under Alternative 1, wastewater from the northern section of Long Pond would be conveyed by an 8-inch gravity trunk sewer on Route 28 westerly to a gravity trunk sewer on Phinney's Lane. The Phinney's Lane sewer would convey the wastewater flow to a proposed pump station off of Phinney's Lane, in Mother's Park. Wastewater from the southwestern section of Long Pond would be conveyed by an 8-inch gravity trunk sewer on Pine Street westerly to the Mother's Park pump station. The Mother's Park pump station site is shown in Figure 6-7. Wastewater flow from the Mother's Park pump station would discharge to the gravity sewer on Route 28, just east of Harrison Road, through a 4-inch force main.

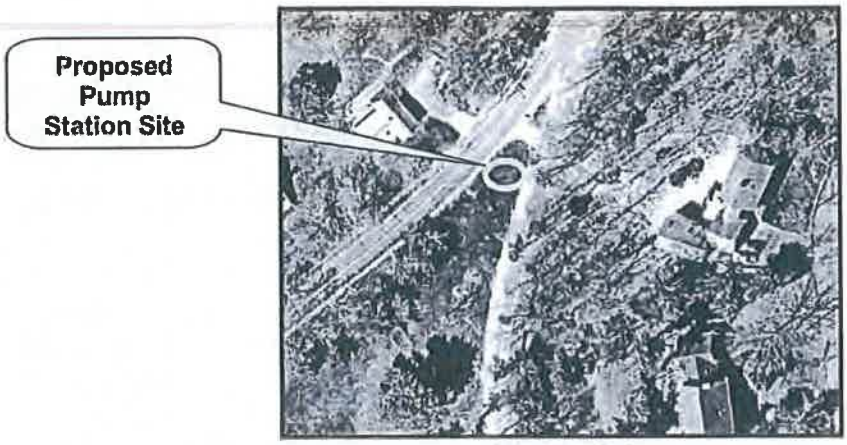

Figure 6-7
Sub-Area 1 Pump Station Site

The collector sewers tributary to the trunk sewers described above would be low pressure, except on Long Pond Circle, in order to avoid deep collector sewer trench excavations and to minimize trunk sewer excavation depths. Gravity collector sewers are proposed on Long Pond Circle. The Sub-Area 1 trunk sewers would generally be constructed less than 10 feet deep, with the exception of the Long Pond Circle area, where approximately 350 feet of sewer on Pine Street would be constructed greater than 15 feet deep and approximately 250 feet of sewer on Pine Street would be constructed greater than 20 feet deep.

Sub-Area 2

Sub-Area 2 includes the portions of the AOC south of Long Pond, between Dunaskin Road and Horatio Lane. Under Alternative 1, an 8-inch gravity trunk sewer would convey wastewater from Dunaskin Road easterly along Pine Street to a proposed pump station between Riverview Lane and the St. Francis Xavier's Cemetery. In addition, an 8-inch gravity trunk sewer would convey wastewater from Horatio Lane westerly along Pine Street to the Pine Street pump station described above. The Pine Street pump station site is shown in Figure 6-8. Wastewater flow from the Pine Street pump station would discharge to the gravity sewer on Childs Street through a 4-inch force main.

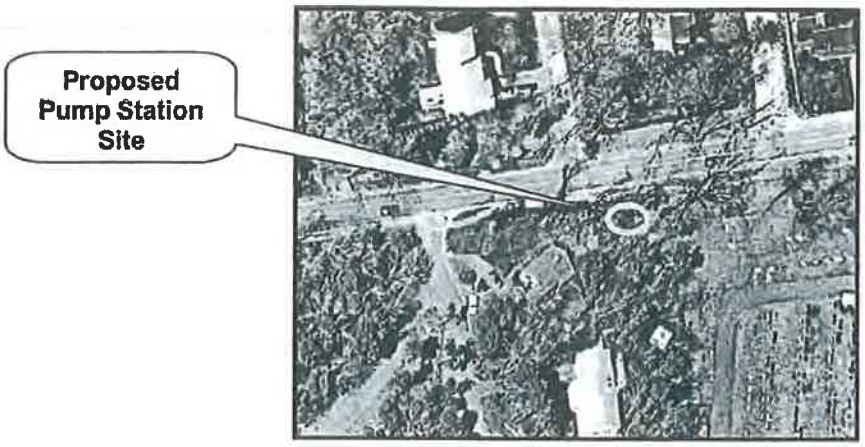

Figure 6-8
Sub-Area 2 Pump Station Site

Low pressure sewers are proposed on Herring Run Drive and on the northern ends of Dunaskin Road and Horatio Lane. Gravity collector sewers are proposed for the remaining streets in this sub-area. The Sub-Area 2 trunk and collector sewers would range in depth from less than 10 feet to greater than 20 feet for some sewer sections. Approximately 700 feet of the 2,100-foot Pine Street trunk sewer would be constructed greater than 15 feet deep and a 200-foot section of sewer on Blantyre Avenue would be constructed greater than 20 feet deep.

Sub-Area 9

Sub-Area 9 includes the portion of the AOC east of Long Pond, from the West Main Street/Route 28 intersection to Pleasant Park Avenue. Under Alternative 1, an 8-inch gravity trunk sewer would convey wastewater flow along West Main Street easterly to the existing sewerage system. The wastewater flow from Sub-Area 1 would be pumped into this trunk sewer while the wastewater flow from Sub-Area 2 would be pumped into an 8-inch gravity sewer on Childs Street, which is tributary to the West Main Street trunk sewer described above.

Under this alternative, deep trench excavation (greater than 15 feet deep) would be required for approximately 800 feet of sewer at the easterly end of the West Main Street trunk sewer. Sewer trench excavations would not exceed 20 feet in this sub-area under this alternative. Low pressure sewers are only proposed on Scottsdale Road in this sub-area.

6.2.1.2 Southern Portion of Lake Wequaquet (Sub-Areas 3 & 4)

Under Alternative 1, the wastewater flow from the southern portion of Lake Wequaquet would be conveyed northerly to the existing force main from the Freezer Road pump

station. The current peak flow from this area is approximately 0.21 mgd and the projected future peak flow, at full build-out and including sewer expansion into the Bowl, is 0.41 mgd. In comparison, the surplus capacity of the 12-inch Freezer Road pump station force main is estimated to be as much as 4.0 mgd (based on a velocity of 8 feet/second), as discussed in section 5. With the addition of the peak flow of 0.41 mgd, the force main velocity would increase from 2.13 feet/second (fps) to 2.94 fps. The operation of the Freezer Road pump station and the force main hydraulics would need to be reviewed if this alternative is pursued to determine the impact on pump operation of increasing the force main flow. Improvements to the pumps may be necessary to accommodate the higher pressure losses that would result from increasing the force main flow, although these improvements would likely be minor for this relatively small velocity change.

As an alternative, wastewater flow from the southern portion of Lake Wequaquet could be conveyed to the nearby Route 28 connection point. However, this connection point is not recommended because it has less surplus hydraulic capacity than the Freezer Road pump station force main connection (0.22 mgd) and would require the replacement of 1,000± feet of gravity sewer and the Mark's Path pump station. Connection to the existing sewerage system on West Main Street was not considered for this area because the Long Pond area would already be directed to this connection point and would utilize all of the remaining surplus capacity. Another alternative considered was to convey the wastewater flow from the southern portion of Lake Wequaquet northerly to the Route 132 gravity sewer. This connection point is not recommended because there is no surplus capacity available in the Route 132 gravity sewer or the Bearses Way pump station.

Sub-Area 3

Sub-Area 3 includes the portion of the AOC southeast of Lake Wequaquet and extends from Conners Road to the north to Crosby Road to the south and is bounded by Phinney's Lane to the east and the lake to the west. Under Alternative 1, wastewater from the northern section of Sub-Area 3 would be conveyed by an 8-inch gravity trunk sewer on Phinney's Lane southerly to a proposed pump station near the intersection of Phinney's Lane and Old Farm Road. Wastewater from the southern section of Sub-Area 3 would be conveyed by an 8-inch gravity trunk sewer on Phinney's Lane northerly to the Old Farm Road pump station described above. The Old Farm Road pump station site is shown in Figure 6-9. Wastewater flow from the Old Farm Road pump station would discharge to the proposed Cape Cod Community College pump station force main on Route 132 through a 6-inch force main.

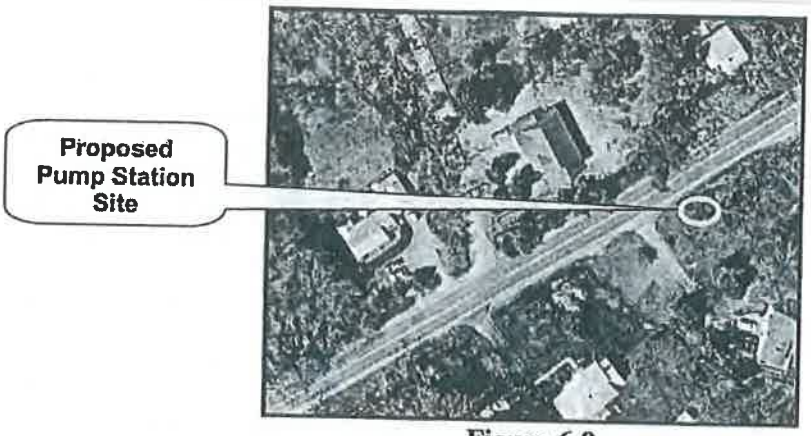

Figure 6-9
Sub-Area 3 Pump Station Site

A significant portion of the Phinney's Lane trunk sewer would be constructed greater than 15 feet deep under this alternative in order to accommodate gravity collector sewers on the side streets tributary to Phinney's Lane. In fact, approximately 2,200 feet of the 3,700-foot Phinney's Lane trunk sewer (59%) would be constructed greater than 15 feet deep and approximately 800 feet of the trunk sewer would be constructed greater than 20 feet deep. Low pressure sewers are proposed only on Center Lane in this sub-area, under Alternative 1.

Sub-Area 4

Sub-Area 4 includes the portion of the AOC southwest of Lake Wequaquet and extends from Annable Point Road to the west to Phinney's Lane to the east and is bounded by Great Marsh Road to the south and the lake to the north. Under Alternative 1, wastewater from the western portion of Sub-Area 4 would be conveyed by an 8-inch gravity trunk sewer on Great Marsh Road easterly to Juniper Road and then northerly along Juniper Road to Lake Drive. The 8-inch trunk sewer on Lake Drive would subsequently convey the wastewater flow into a proposed pump station in the vicinity of the Wequaquet Estates beach on Lake Drive. Wastewater flow from Brezner Road and Pond Street would be conveyed through 8-inch gravity sewers westerly to the Lake Drive pump station. The Lake Drive pump station would discharge into the Sub-Area 3 gravity trunk sewer on Phinney's Lane through a 4-inch force main. The Lake Drive pump station site is shown in Figure 6-10.

In order to avoid excessively deep trench excavations, low pressure sewers would be constructed in the Annable Point Road area and on Hayes Road. Gravity collector sewers are proposed for the remaining streets in this sub-area. Deep trench excavations (greater than 15 feet deep) would be required along Juniper Road and a short section of

Great Marsh Road. Sewer trench excavations would not exceed 20 feet in this sub-area under this alternative.

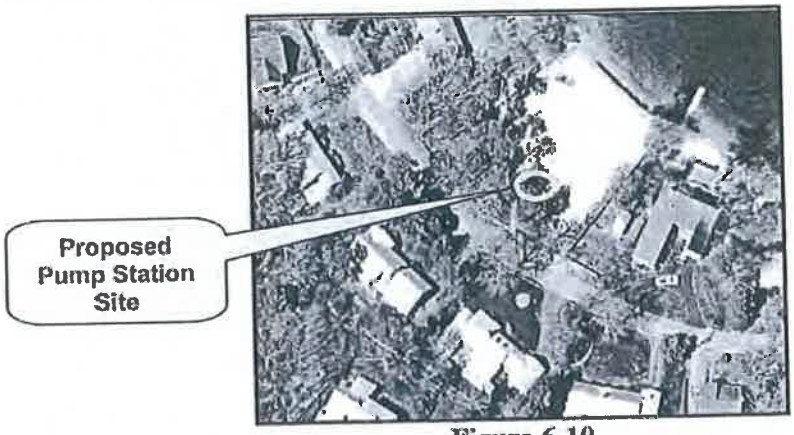

Figure 6-10
Sub-Area 4 Pump Station Site

6.2.1.3 Northern Portion of Lake Wequaquet (Sub-Areas 5, 6, 7 & 8)

Under Alternative 1, the wastewater flow from the northern portion of Lake Wequaquet would be conveyed to the existing force main from the Freezer Road pump station, similar to the southern portion of Lake Wequaquet. As discussed in Section 5, we have assumed that only one of the two force mains will be available to accept wastewater flow from the AOC. The current peak flow from the northern portion of Lake Wequaquet is approximately 0.61 mgd and the projected future peak flow, at full build-out and including sewer expansion into the Bowl, is 0.95 mgd. When the flow from the southern portion of Lake Wequaquet is also considered, the current peak flow from the northern and southern portions of Lake Wequaquet is approximately 0.82 mgd and the projected future peak flow, at full build-out and including sewer expansion into the Bowl, is 1.36 mgd. In comparison, the surplus capacity of the 12-inch Freezer Road pump station force main is estimated to be as much as 4.0 mgd (based on a velocity of 8 fps), as noted previously. With the addition of the peak flow of 1.36 mgd, the wastewater flow through the force main would increase from 1.08 mgd to 2.44 mgd and the velocity would increase from 2.13 fps to 4.79 fps. This pipe velocity is well within what is considered an acceptable range. The operation of the Freezer Road pump station and the force main hydraulics would need to be reviewed if this alternative is pursued to determine the impact on pump operation of increasing the force main flow. Improvements to the pumps may be necessary to accommodate the higher pressure losses that would result from increasing the force main flow.

As an alternative, wastewater flow from the northern portion of Lake Wequaquet could be conveyed to the Route 28 connection. However, this connection point is not recommended because it has less surplus hydraulic capacity than the Freezer Road

pump station force main connection and would require the replacement of 2,500± feet of gravity sewer, the Mark's Path pump station, and the Mark's Path pump station force main. Another alternative considered was to convey the wastewater flow from the northern portion of Lake Wequaquet northerly to the Route 132 gravity sewer. This connection point is not recommended because there is no surplus capacity in the Route 132 gravity sewer.

Sub-Area 5

Sub-Area 5 includes the portion of the AOC northwest of Lake Wequaquet and is bounded by Lakewood Drive to the south, Shootflying Hill Road to the west, Lakeview Drive to the north, and the lake to the east. Under Alternative 1, wastewater from the southern portion of Sub-Area 5 would be conveyed by an 8-inch gravity trunk sewer on Shootflying Hill Road northerly to a proposed pump station at the Town beach on Shootflying Hill Road. Wastewater flow from the northern portion of Sub-Area 5 would be conveyed by an 8-inch gravity trunk sewer on Shootflying Hill Road southerly to the Shootflying Hill Road pump station described above. The Shootflying Hill Road pump station site is shown in Figure 6-11. Wastewater flow from the Shootflying Hill Road pump station would discharge to the gravity sewer on Shootflying Hill Road, just south of the Lakeview Drive, through a 4-inch force main.

Low pressure sewers are proposed on Lakewood Drive, Tern Lane, and Johnson Lane in this sub-area. The majority of the proposed gravity sewers would be less than 15 feet deep, with the exception of 800 feet of sewer at the southern end of this drainage area on Shootflying Hill Road. None of the sewer depths would exceed 20 feet.

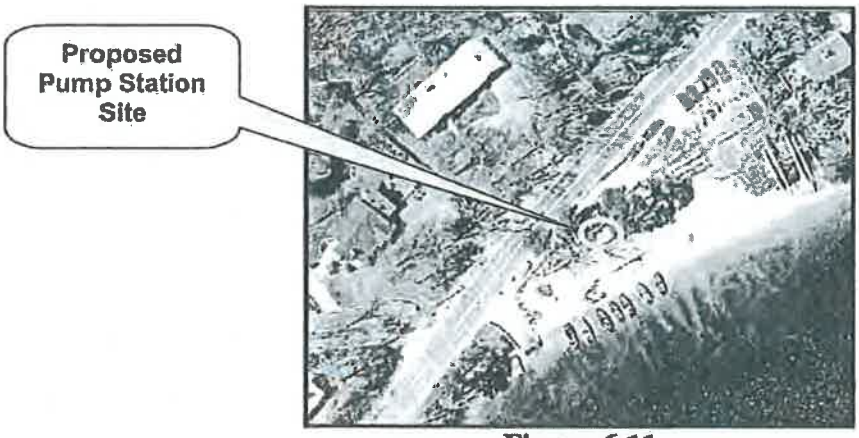

Figure 6-11
Sub-Area 5 Pump Station Site

Sub-Area 6

Sub-Area 6 includes the portion of the AOC north of Lake Wequaquet and is bounded by Shootflying Hill Road to the east, a point 750 feet west of Bunny Run to the west,

Route 132 to the north and Lake Wequaquet to the south. This sub-area includes the Nyes Neck peninsula. Under Alternative 1, wastewater from the eastern portion of Sub-Area 6 would be conveyed by an 8-inch gravity trunk sewer on Lakeview Drive and Pleasant Pines Avenue easterly to a proposed pump station on Pleasant Pines Avenue. An 8-inch gravity sewer would also convey wastewater flow to the Pleasant Pines Avenue pump station from a few homes west of the proposed pump station. The Pleasant Pines Avenue pump station site is shown in Figure 6-12. Wastewater flow from the Pleasant Pines Avenue pump station would discharge to the proposed Cape Cod Community College pump station force main on Route 132 through 6-inch and 8-inch force mains.

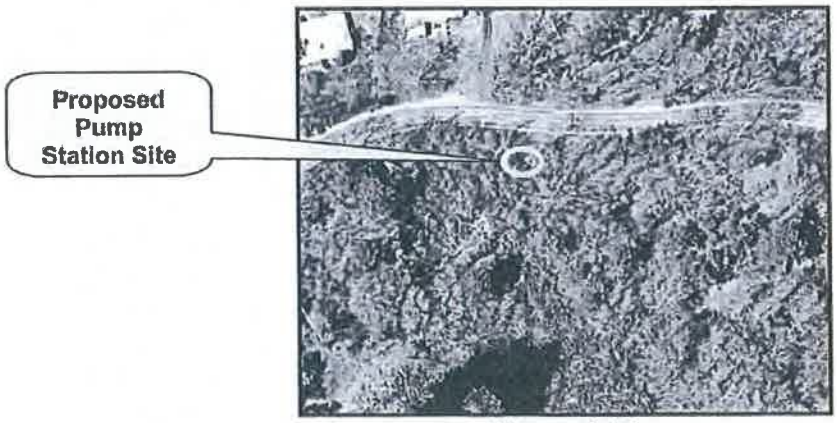

Figure 6-12
Sub-Area 6 Pump Station Site

The excavation depths of the proposed gravity sewers in this sub-area would not exceed 15 feet.

The Nyes Neck peninsula would be served primarily by low pressure sewers under this alternative. Gravity sewers and conventional pump stations were considered for this area and preliminary layouts were prepared. However, due to the anticipated difficulties in constructing pump stations in this wet, low-lying area, gravity sewers and conventional pump stations were eliminated from consideration for the peninsula.

Sub-Area 7

Sub-Area 7 includes the portion of the AOC north of Lake Wequaquet and is bounded by a point 750 feet west of Bunny Run to the west, Conners Road to the east, Route 132 and Shallow Pond to the north, and Bearse Pond and Lake Wequaquet to the south. This sub-area includes the Lakeside Drive peninsula. Under Alternative 1, wastewater from the northern portion of Sub-Area 7 would be conveyed by an 8-inch gravity trunk sewer southeasterly on Huckins Neck Road to a proposed pump station on Huckins

Neck Road, between Holly Point Road and Lakeview Avenue. Wastewater flow from the southeastern portion of Sub-Area 7 would be conveyed by an 8-inch gravity trunk sewer on Huckins Neck Road northwesterly to the Huckins Neck Road pump station described above. The Huckins Neck Road pump station site is shown in Figure 6-13. Wastewater flow from the Huckins Neck Road pump station would discharge to the proposed Cape Cod Community College pump station force main on Route 132 through 4-inch and 8-inch force mains.

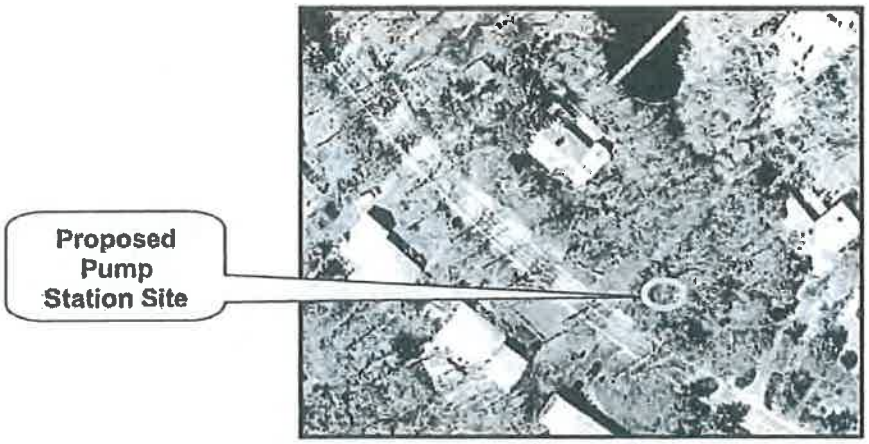

Figure 6-13
Sub-Area 7 Pump Station Site

Because of the rolling, hilly terrain on Huckins Neck Road, deep trench excavation would be required for several sewer sections along this street. In fact, approximately 2,900 feet of sewer would require trench excavation greater than 15 feet deep and approximately 700 feet of sewer would require trench excavation greater than 20 feet deep. Construction is expected to be especially difficult along these deep sewer sections on Huckins Neck Road because of the proximity of the adjacent ponds and high groundwater conditions.

The Lakeside Drive peninsula would be served primarily by low pressure sewers under this alternative. Gravity sewers and conventional pump stations were considered for this area and preliminary layouts were prepared. However, due to the anticipated difficulties in constructing pump stations in this wet, low-lying area, gravity sewers were eliminated from consideration for the peninsula.

Sub-Area 8

Sub-Area 8 includes the portion of the AOC northeast of Shallow Pond and is bounded by Shallow Pond Drive to the west, Phinney's Lane to the east, Route 132 to the north and Shallow Pond to the south. Under Alternative 1, wastewater from the western portion of Sub-Area 8 would be conveyed by an 8-inch gravity trunk sewer easterly on

Route 132 to a proposed pump station on Route 132, near Old Strawberry Hill Road. Wastewater flow from the southeastern portion of Sub-Area 8 would be conveyed by an 8-inch gravity trunk sewer on Old Strawberry Hill Road northerly to the Route 132 pump station described above. The Route 132 pump station site is shown in Figure 6-14. Note that this pump station site may need to be changed to accommodate the Route 132 improvements currently being designed. Wastewater flow from the Route 132 pump station would discharge to the proposed Cape Cod Community College pump station force main on Route 132 through a 4-inch force main.

The majority of the sewers would be less than 15 feet depth, with the exception of a 350-foot sewer section on Old Strawberry Hill Road, which would be 15 to 20 feet deep. Sewer depths would not exceed 20 feet.

Low pressure sewers would be constructed on Crestview Circle, Regatta Drive and Dacey Drive as part of this alternative.

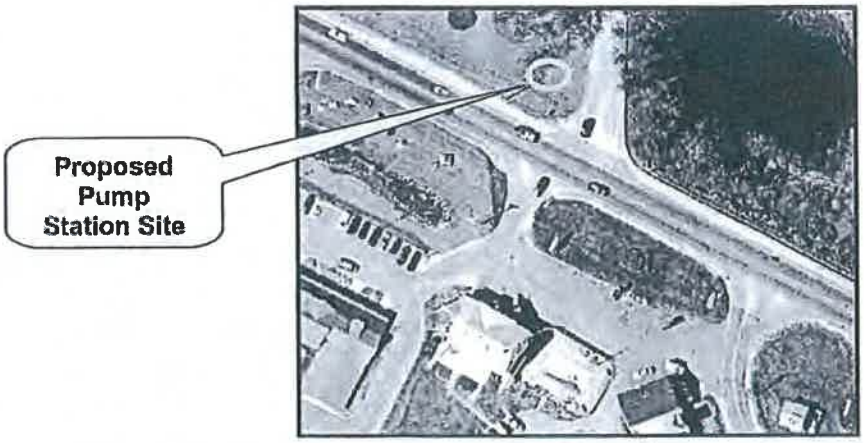

Figure 6-14
Sub-Area 8 Pump Station Site

6.2.1.4 Cape Cod Community College

The Cape Cod Community College (CCCC) is currently designing a wastewater pump station that would allow it to send its wastewater flow to the Town sewerage system and subsequently abandon the existing college septic systems. The design of the piping from the college to the Town sewerage system is a component of this project and has been considered as part of this evaluation.

Under Alternative 1, a force main would be constructed from the Cape Cod Community College pump station, along Route 132, to the existing Freezer Road pump station force main. As discussed previously, the sub-areas around Lake Wequaquet would also be conveyed to the Freezer Road pump station force main.

The current peak flow from the CCC is estimated as approximately 0.06 mgd and the projected future peak flow, based on growth over a 20-year period, is 0.17 mgd. When the flows from the AOC around Lake Wequaquet are also considered, the current peak flow from the AOC around Lake Wequaquet and the CCCC is approximately 0.88 mgd and the projected future peak flow is 1.53 mgd. In comparison, the surplus capacity of the 12-inch Freezer Road pump station force main is estimated to be as much as 4.0 mgd (based on a velocity of 8 fps), as noted previously. With the addition of the peak flow of 1.53 mgd, the wastewater flow through the force main would increase from 1.08 mgd to 2.61 mgd and the velocity would increase from 2.13 fps to 5.12 fps. The operation of the Freezer Road pump station and the force main hydraulics would need to be reviewed if this alternative is pursued to determine the impact on pump operation of increasing the force main flow. Improvements to the pumps may be necessary to accommodate the higher pressure losses that would result from increasing the force main flow.

6.2.2 Alternative 2 - Gravity & LP Sewers, 11 Pump Stations

Alternative 2, shown in Figure 6-15, was developed to reduce the deep excavation that would be required under Alternative 1 on Huckins Neck Road (Sub-Area 7), Phinney's Lane (Sub-Area 3), and Pine Street (Sub-Area 2). Excavation depths exceeding 20 feet would be required in these areas under Alternative 1. With the changes provided by Alternative 2, the excavation depths have been limited to no more that 20 feet. In order to reduce excavation depths, additional pump stations have been proposed on Huckins Neck Road and Phinney's Lane and additional low pressure sewers have been proposed for collector sewers tributary to Phinney's Lane and Pine Street.

Vacuum sewers were not considered as part of this alternative, similar to Alternative 1. This alternative is described in detail in the paragraphs that follow and is summarized in Table 6-3.

Alternative 2 includes:

- 129,550 feet (25± miles) of proposed sewer
- 60,980 feet of gravity sewers (47% of total)
- 11 proposed pump stations and replacement of the Main Street pump station
- 401 grinder pumps

Notes:

(1) Includes replacement of the Main Street pump station and diverting flow from the pump station to the Old Colony Road pump station force main.

6.2.2.1 Long Pond (Sub-Areas 1, 2 & 9)

The Long Pond area wastewater flows would be conveyed to the existing sewerage system on West Main Street, similar to Alternative 1. Minor layout changes have been proposed in the Long Pond Area as part of Alternative 2 to reduce excavation depths on Pine Street and are describe below.

Sub-Area 1

Under Alternative 2, Sub-Area 1 would be served as described for Alternative 1, except that the collector sewers on Long Pond Circle would be low pressure sewers rather than gravity sewers. As a result of this change, the maximum excavation depth on Pine Street is reduced from approximately 22 feet under Alternative 1 to approximately 16 feet in the area of Long Pond Circle.

Sub-Area 2

Under Alternative 2, Sub-Area 2 would be served as described for Alternative 1, except that low pressure sewers are proposed at the north end of Blantyre Avenue rather than gravity sewers. As a result of this change, the maximum excavation depth on Blantyre Avenue is reduced from approximately 21 feet to approximately 12 feet. In addition, the maximum excavation depth on Pine Street, in the area of Blantyre Avenue, is reduced from approximately 19 feet under Alternative 1 to approximately 10 feet.

Sub-Area 9

The proposed Alternative 2 layout is the same as the proposed Alternative 1 layout for this Sub-Area.

6.2.2.2 Southern Portion of Lake Wequaquet (Sub-Areas 3 & 4)

Similar to Alternative 1, the wastewater flow from the southern portion of Lake Wequaquet would be conveyed northerly to the existing force main from the Freezer Road pump station under this alternative. Layout changes have been proposed in the southern portion of Lake Wequaquet as part of Alternative 2 to reduce excavation depths on Phinney's Lane.

Sub-Area 3

The differences between the Alternative 1 and Alternative 2 layouts for this sub-area are summarized below:

1. Under Alternative 2, Sub-Area 3 would be served by two pump stations rather than one.

2. Under Alternative 2, the collector sewers on Loomis Lane, Richards Lane, Old Farm Road, and Conners Road would be low pressure sewers rather than gravity sewers.

The changes described above would reduce the maximum excavation depth along Phinney's Lane from 25 feet to 14 feet and the majority of the piping on this street would be less than 10 feet deep.

Sub-Area 3 was divided into two parts, reflecting the two pump station service areas: Sub-Area 3A and Sub-Area 3B, as shown in Figure 6-15. Sub-Area 3A includes the northern portion of Sub-Area 3, north of Strawberry Hill Road while Sub-Area 3B includes the southern portion of Sub-Area 3, south of Strawberry Hill Road. The Sub-Area 3A pump station would be located near the intersection of Phinney's Lane and Old Farm Road, similar to the Alternative 1 Sub-Area 3 pump station location. The Sub-Area 3B pump station would be located between Crosby Road and Tellegen Trail on Phinney's Lane, near the culvert/drainage channel between Lake Wequaquet and Long Pond. The Sub-Area 3B pump station site is shown in Figure 6-16.

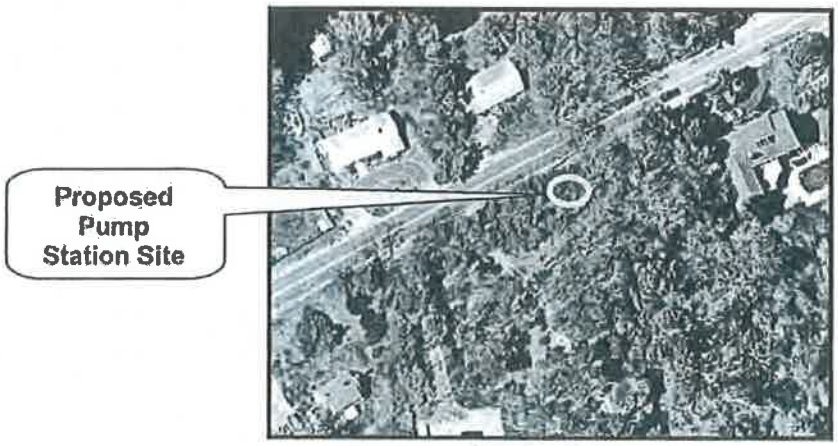

Figure 6-16
Sub-Area 3B Pump Station Site

Sub-Area 4

The proposed Alternative 2 layout is the same as the proposed Alternative 1 layout for this Sub-Area.

6.2.2.3 Northern Portion of Lake Wequaquet (Sub-Areas 5, 6, 7 & 8)

Similar to Alternative 1, the wastewater flow from the northern portion of Lake Wequaquet would be conveyed northerly to the existing force main from the Freezer Road pump station under this alternative. Layout changes have been proposed in the

northern portion of Lake Wequaquet as part of Alternative 2 to reduce excavation depths on Huckins Neck Road.

Sub-Area 5

The proposed Alternative 2 layout is the same as the proposed Alternative 1 layout for this Sub-Area.

Sub-Area 6

The proposed Alternative 2 layout is the same as the proposed Alternative 1 layout for this Sub-Area.

Sub-Area 7

Under Alternative 2, Sub-Area 7 would be served by three pump stations on Huckins Neck Road in order to reduce the deep excavations that would be required under Alternative 1, which would be served by one pump station. Under Alternative 1, especially difficult construction was identified along Huckins Neck Road. Sub-Area 7 is divided into three parts as part of this alternative, reflecting the three pump station service areas: Sub-Areas 7A, 7B, and 7C, as shown in Figure 6-15. The pump stations serving Sub-Areas 7A, 7B, and 7C are shown in Figures 6-17, 6-18, and 6-19, respectively.

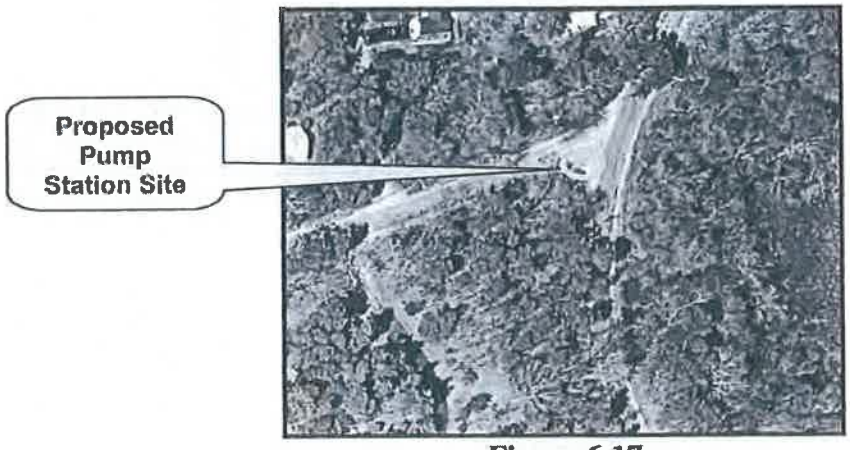

Figure 6-17
Sub-Area 7A Pump Station Site

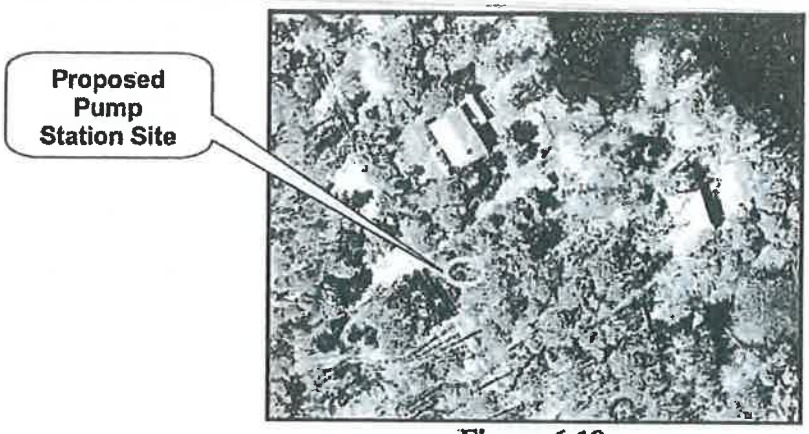

Figure 6-18
Sub-Area 7B Pump Station Site

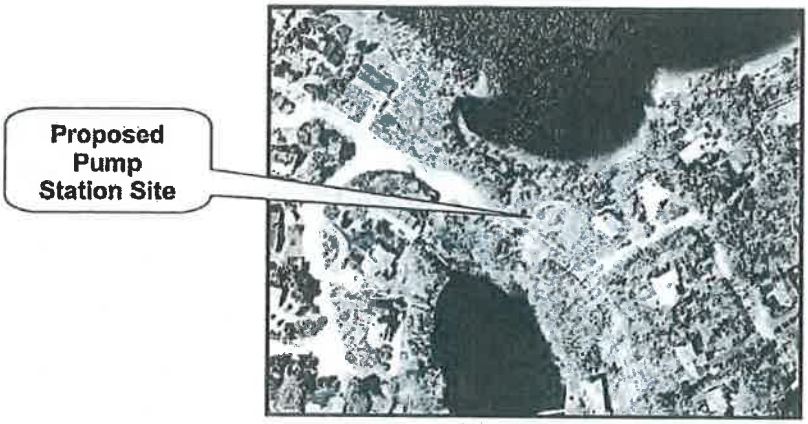

Figure 6-19
Sub-Area 7C Pump Station Site

The Sub-Area 7A pump station would be located at the intersection of Pleasant Pines Avenue and Huckins Neck Road, the Sub-Area 7B pump station would be located on Huckins Neck Road, approximately 300 feet northwest of Holly Point Road, and the Sub-Area 7C pump station would be located on Huckins Neck Road, near Cottonwood Lane.

By constructing three pump stations on Huckins Neck Road, the maximum excavation depth is reduced from approximately 25 feet to approximately 19 feet and the quantity of deep sewers is reduced from approximately 2,900 feet to approximately 800 feet. Although deep sewer construction is reduced significantly by this alternative, the construction of the three pump stations is still a concern because they are expected to be approximately 10 feet deeper than the invert of the sewer inlet pipe.

Sub-Area 8

The proposed Alternative 2 layout is the same as the proposed Alternative 1 layout for this sub-area.

6.2.2.4 Cape Cod Community College

The proposed Alternative 2 layout for the college is the same as the proposed Alternative 1 layout.

6.2.3 Alternative 3 - Gravity & LP Sewers, 5 Pump Stations

Alternative 3, shown in Figure 6-20, was developed to further reduce excavation depths in the northern portion of Lake Wequaquet from that shown for Alternatives 1 and 2 by installing low pressure sewers throughout this area. Vacuum sewers were not considered as part of this alternative, similar to Alternatives 1 and 2. This alternative is described in detail in the paragraphs that follow and is summarized in Table 6-4.

Alternative 3 includes:

- 120,210 feet (23± miles) of proposed sewer
- 36,240 feet of gravity sewers (30% of total)
- 5 proposed pump stations and replacement of the Main Street pump station
- 598 grinder pumps

6.2.3.1 Long Pond (Sub-Areas 1, 2 & 9)

The proposed Alternative 3 layout is the same as the proposed Alternative 1 layout for these sub-areas. The Alternative 1 layout is preferred over the Alternative 2 layout for Sub-areas 1, 2, and 9 because Alternative 1 provides more gravity sewers and, correspondingly, less low pressure sewers and fewer grinder pumps at essentially the same construction cost as the Alternative 2 layout. There is only a 1% difference between the Alternative 1 costs and Alternative 2 costs for Sub-Areas 1 and 2 and no cost difference for Sub-Area 9.

6.2.3.2 Southern Portion of Lake Wequaquet (Sub-Areas 3 & 4)

The proposed Alternative 3 layout is the same as the proposed Alternative 1 layout for these sub-areas. The Alternative 1 layout is preferred over the Alternative 2 layout for

Notes:

(1) Includes replacement of the Main Street pump station and diverting flow from the pump station to the Old Colony Road pump station force main.

Sub-area 3 because it is projected to be significantly less expensive and requires fewer pump stations. The sewer layout in Sub-Area 4 is the same for Alternatives 1 and 2.

6.2.3.3 Northern Portion of Lake Wequaquet (Sub-Areas 5, 6, 7 & 8)

Under Alternative 3, the northern portion of Lake Wequaquet would be served by low pressure sewers and grinder pumps. This alternative would eliminate deep sewer construction in this area and minimize pump station construction. However, because pipe velocity and headloss must be balanced in a low pressure sewer system, the low pressure sewers in this area would be sized for a specific flow range and would not be able to accommodate significant future expansion. In particular, the low pressure sewers proposed within the AOC along Shootflying Hill Road would not be able to accommodate the full build-out flows projected within the relatively large Bowl area to the west.

One pump station is expected to be needed for this area to pump flow from Sub-Areas 5, 6, and 7 into the CCCC pump station force main. This pump station is expected to be necessary because the pressure in the low pressure sewer at the downstream end of these sub-areas would be too low to overcome the pressure in the Cape Cod Community College pump station force main. The low pressures that are projected at the downstream end of the system are expected to occur because of the long length of piping from the upstream end to the downstream end of this large sub-system, which results in high pipe friction losses.

This pump station would be located near the intersection of Route 132 and Huckins neck Road, as shown in Figure 6-21. Note that this pump station site may need to be changed to accommodate the Route 132 improvements currently being designed.

The wastewater flow from Sub-Area 8 would discharge directly into the CCCC pump station force main on Route 132, near Old Strawberry Hill Road. The pressure available at the downstream end of the proposed low pressure sewer system in this relatively small sub-area is expected to be great enough to overcome the pressure in the Cape Cod Community College pump station force main and a pump station to serve this area is not expected to be necessary.

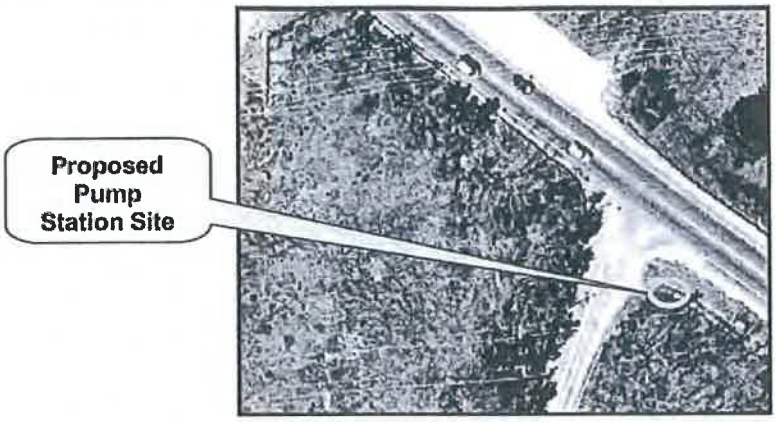

Figure 6-21
Sub-Areas 5, 6 & 7 Pump Station Site

6.2.3.4 Cape Cod Community College

The proposed Alternative 3 layout for the college is the same as the proposed Alternative 1 layout.

6.2.4 Alternative 4 – Gravity, LP and Vacuum Sewers, 4 Pump Stations, and 2 Vacuum Stations

Alternative 4, shown in Figure 6-22, is similar to Alternative 3 except that Sub-Areas 6 and 7 would be served by vacuum sewers rather than low pressure sewers. This alternative is described in detail in the paragraphs that follow and is summarized in Table 6-5.

Alternative 4 includes:

- 125,400 feet (24± miles) of proposed sewer
- 36,240 feet of gravity sewers (29% of total)
- 4 proposed pump stations, 2 proposed vacuum stations, and replacement of the Main Street pump station
- 287 grinder pumps
- 311 valve pits

Table 6-5
Alternative 4 Sewer Layout Summary

Sub-Area	Gravity Sewer Length (ft)	Low Pressure Sewer Length (ft)	Vacuum Sewer Length (ft)	Force Main Length (ft)	Total Pipe Length (ft)	No. of Pump/Vacuum Stations	No. of Grinder Pumps	No. of Valve Pits
1	6,760	4,240	0	3,400	14,400	1	51	0
2	7,340	2,420	0	2,600	12,360	1	14	0
3	10,860	650	0	6,500	18,010	1	25	0
4	7,460	5,620	0	850	13,930	1	63	0
5	0	8,330	0	0	8,330	0	46	0
6	0	0	11,140	2,700	13,840	1	0	67
7	0	0	23,230	2,500	25,730	1	0	244
8	0	6,810	0	0	6,810	0	80	0
9	3,820	470	0	0	4,290	0	8	0
CCCC	0	0	0	6,300	6,300	0	0	0
Improvements to Existing Sewerage System (1)	0	0	0	1,400	1,400	1	0	0
Total	**36,240**	**28,540**	**34,370**	**26,250**	**125,400**	**7**	**287**	**311**

Notes:

(1) Includes replacement of the Main Street pump station and diverting flow from the pump station to the Old Colony Road pump station force main.

6.2.4.1 Long Pond (Sub-Areas 1, 2 & 9)

The proposed Alternative 4 layout is the same as the proposed Alternative 1 layout for these sub-areas. Vacuum sewers were considered for these sub-areas but were not expected to be cost-effective because either the vacuum sewers would need to be installed at depths similar to those needed for gravity sewers or vacuum stations would be needed to serve relatively small areas.

Alternatively, a hybrid system was considered, which would consist of vacuum sewers and low pressure sewers. This alternative was also not expected to be cost-effective since it would require that low pressure sewers be constructed in a large portion of this area and that, correspondingly, a vacuum station be constructed to serve a relatively small area.

6.2.4.2 Southern Portion of Lake Wequaquet (Sub-Areas 3 & 4)

The proposed Alternative 4 layout is the same as the proposed Alternative 1 layout for these sub-areas. The majority of these sub-areas would be served by gravity sewers, which was considered appropriate for these areas.

6.2.4.3 Northern Portion of Lake Wequaquet (Sub-Areas 5, 6, 7 & 8)

Sub-Areas 5 & 8

The proposed Alternative 4 layout is the same as the proposed Alternative 3 layout for these sub-areas; low pressure sewers are proposed. Vacuum sewers were considered for Sub-Area 5 but because of the significant grade changes in this area (ranging from 38± feet to 76± feet), vacuum sewers are not expected to be cost-effective. The two vacuum sewer vendors contacted (AIRVAC and Roediger) provided vacuum sewer layout information that confirmed this. Similarly, vacuum sewers were considered for Sub-Area 8 but because of the significant grade changes in this sub-area (ranging from 48± feet to 84± feet), vacuum sewers are not expected to be cost-effective for much of this sub-area. This was also confirmed by the two vacuum sewer vendors, based on the vacuum sewer layout information provided.

Sub-Areas 6 & 7

Under Alternative 4, Sub-Areas 6 and 7 would be served by vacuum sewers. These two sub-areas were determined to be appropriate for vacuum sewers because of the smaller changes in grade throughout these areas. A vacuum station would be constructed to serve each sub-area under this alternative. The Sub-Area 6 vacuum station would be located on Pleasant Pines Avenue, at the same site as the Sub-Area 6 pump stations under Alternatives 1 and 2. The Sub-Area 7 vacuum station would be

located on Huckins Neck Road, at the same site as the Sub-Area 7B pump station under Alternative 2.

7.1 GENERAL

This section outlines the anticipated permitting requirements of the various federal, state, regional, and local agencies and authorities that have jurisdiction over the construction of the proposed project. Although the four alternatives will require, in many cases, the same permits, the permitting effort is expected to vary among the four alternatives.

7.2 FEDERAL PERMIT PROGRAMS

7.2.1 NPDES General Stormwater Permit

The proposed project will be under the jurisdiction of the EPA Phase I Stormwater Program - Large Construction Activities, because greater than 5 acres will be disturbed. Under the Phase I Program, owners/operators of construction activities that disturb greater than 5 acres are required to obtain a General Permit, which is typically re-issued every 5 years. The General Permit requirements include:

1. The preparation of a Storm Water Pollution Prevention Plan (SWPPP). This document is not submitted to the EPA but must be on-site during construction activities and is subject to review by regulatory authorities inspecting the work.

2. The preparation of weekly inspection reports and periodic progress reports documenting that the SWPPP is being followed. These reports are required by the SWPPP.

3. The preparation and submittal to the EPA of a stormwater Notice of Intent (NOI) two days prior to the start of construction.

4. The preparation of a Notice of Termination at the end of the project.

Note that the stormwater pollution prevention requirements are expected to also be subject to local stormwater ordinances that are required by the Municipal Separate Storm Sewer System (MS4) program. The DEP/EPA have determined that Barnstable is under the jurisdiction of this program and regulated communities are required to apply for permit coverage 90 days from when the EPA issues the General Stormwater Permit, which is expected in May, 2003.

7.2.2 Section 404 of the Clean Water Act

Section 404 of the Clean Water Act (CWA) regulates the discharge of dredged material into "Waters of the United States", which includes wetlands. The U.S. Army Corps of

Engineers has regulatory authority of this program through 33 CFR parts 320-330. Within the limits of the project, any filling, excavation, or soil compaction from the movement of vehicles within wetlands in excess of 5,000 square feet will require Programmatic General Permit review by the U.S. Army Corps of Engineers.

Wetland disturbances greater than 5,000 square feet are not anticipated, based on the layout of the four alternatives developed. A more detailed evaluation of the need for this permit will be performed during design, once the preferred alternative is selected and pump station locations are finalized.

7.2.3 Federal Endangered Species Act of 1973 (16 U.S.C. 1531)

In the event that a permit is required from a federal agency (such as the U.S. Army Corps of Engineers or U.S. EPA), the permit will not be valid unless the U.S. Fish and Wildlife Service issues a letter stating that the project is not likely to jeopardize the continued existence of any federally listed endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Federal Endangered Species Act (FESA) review is not triggered if no federal permits are required by another agency.

Because a federal permit will be needed for the project (the General Stormwater Permit), the U.S. Fish and Wildlife has been contacted to obtain their input on whether there are any federally listed endangered species in the project area. No federally listed or proposed, threatened or endangered species are known to occur in the project area, with the exception of the occasional transient bald eagles.

7.2.4 National Historic Preservation Act of 1966 (16 U.S.C. 470)

In the same fashion as above, the need for a federal permit requires the need for project review under this statute. If the project is likely to occur within the proximity of historic, cultural or archaeological features listed in the *National Register of Historic Places*, letters from the Massachusetts Historical Commission (MHC) and local Native American tribal council will be needed stating no adverse effects to these resources will occur as a result of the project.

As noted above, because a federal permit will be needed for this project (the General Stormwater Permit), the MHC and the local Native American tribal council have been contacted to determine if any historic, cultural or archaeological features will be impacted by the proposed work. The MHC has indicated that there are three recorded historical archaeological sites and one recorded ancient Native American site within the project area. In addition, the MHC has indicated that the project area is archaeologically sensitive and likely to contain additional archaeological sites and historic resources, although the project area has not been systematically surveyed by

professional archaeologists. The MHC will be provided with another opportunity to review project impacts through the ENF and EIR. The Wampanoag Tribal Historic Preservation Officer has not responded to our request for information.

7.3 STATE PERMIT PROGRAMS

7.3.1 Massachusetts Wetlands Protection Act (M.G.L. Chapter 131, Section 40)

Wetland resource areas, consisting primarily of Bordering Land Subject to Flooding (BLSF), Isolated Land Subject to Flooding (ILSF), Bordering Vegetated Wetlands (BVWs), and Land Under Waterbodies and Waterways (LUWBW) exist in the Area of Concern (AOC), especially in the Nyes Neck Road area, as shown in Figure 7-1. The majority of the proposed sewers will be constructed within existing roadways and will not impact nearby wetland areas, assuming that standard good construction practices are employed, including proper placement of haybales and siltation fences, and appropriate dewatering methodologies.

However, because new sewers in the study area will be constructed within the 100-foot wetlands buffer zone under each alternative, the sewer construction work will be regulated by the Massachusetts Wetlands Protection Act (WPA) and a wetlands permit (Order of Conditions) will be required. As part of the permitting process, the Barnstable Department of Public Works will need to file a Notice of Intent with the local Conservation Commission and the MADEP. The local Conservation Commission is responsible for determining whether construction will be allowed in areas under the jurisdiction of the WPA and whether the construction is subject to conditions/restrictions to protect these areas.

The Town Conservation Administrator (Mr. Rob Gatewood) indicated during a meeting regarding this project on February 4, 2003 that wetlands along the streets where new sewers are proposed can be delineated based on current state and local GIS mapping and a more detailed delineation, by flagging wetlands and subsequent field verification, is not required. However, where construction activity is proposed outside of the existing roadways, and it encroaches on wetland areas, a more detailed delineation of wetland areas, through flagging and field verification, is required in order to quantify impacts in detail.

Wetlands delineation will be performed in accordance with guidelines established by the MADEP and 310 CMR 10.00, and the appropriate resource area designations assigned.

It is important to note that this project may proceed under the Limited Project provisions of the WPA, as outlined in 310 CMR 10.53(3)(d):

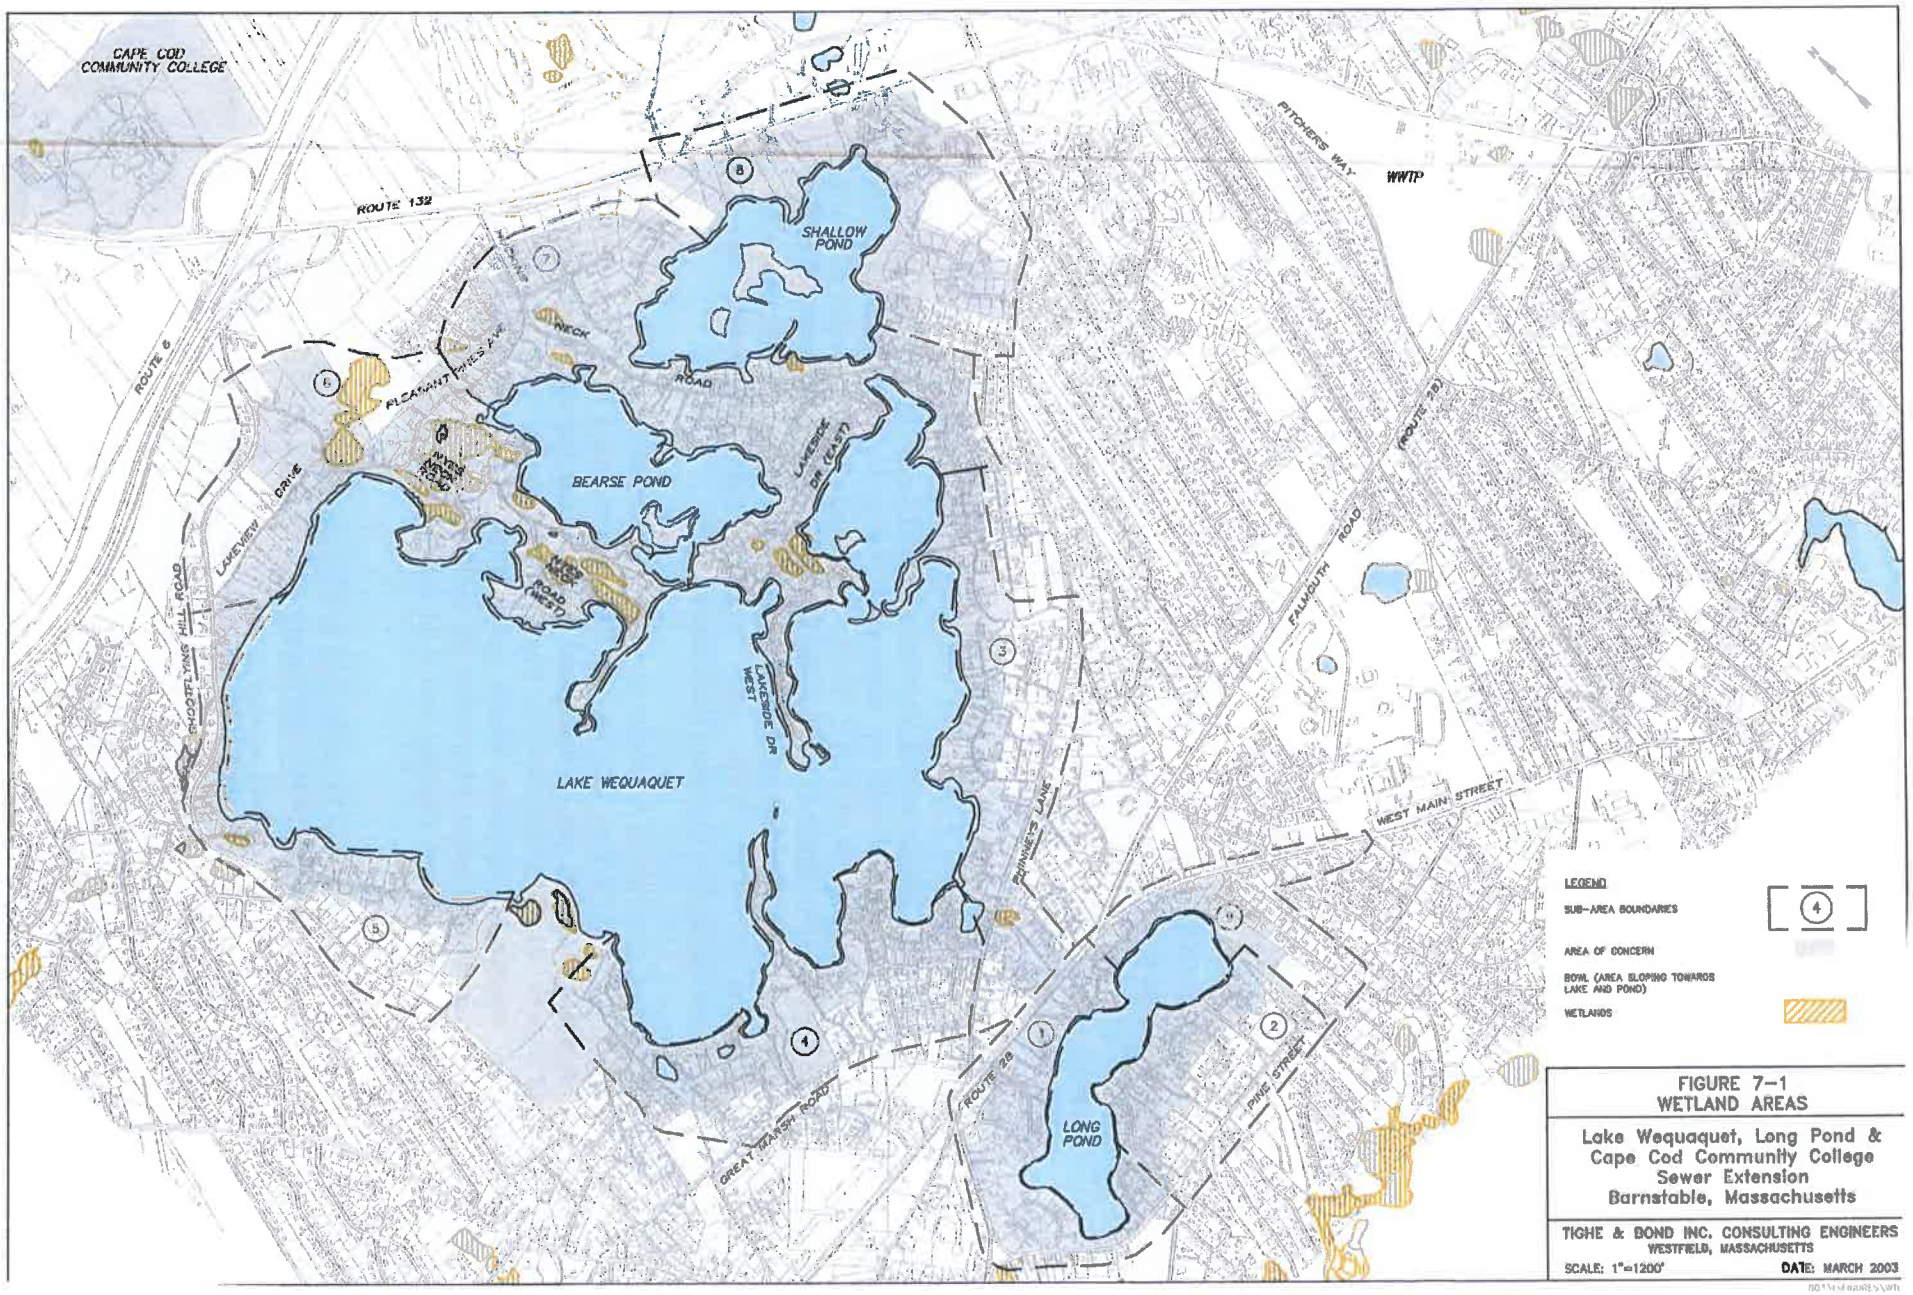

FIGURE 7-1
WETLAND AREAS

Lake Wequaquet, Long Pond & Cape Cod Community College Sewer Extension
Barnstable, Massachusetts

TIGHE & BOND INC. CONSULTING ENGINEERS
WESTFIELD, MASSACHUSETTS

SCALE: 1"=1200' DATE: MARCH 2003

". . . The construction, reconstruction, operation and maintenance of underground and overhead public utilities, such as electrical distribution or transmission lines, or communication, sewer, water, and natural gas lines, may be permitted, in accordance with the following general conditions and any additional conditions deemed necessary by the reserving authority.

1. *the reserving authority may require a reasonable alternative route with fewer adverse effects for a local distribution or connecting line not reviewed by the Energy Facilities Siting Council;*
2. *best available measures shall be used to minimize adverse effects during construction;*
3. *the surface vegetation and contours of the area shall be substantially restored; and*
4. *all sewer lines shall be constructed to minimize inflow and leakage . . ."*

Activities that proceed under the Limited Project provisions of the WPA are recognized as generally being beneficial to public welfare, or those that otherwise may not be able to meet the general performance standards of resource areas due to temporary impacts.

Under the WPA, a general wildlife habitat evaluation will need to be conducted in the event the following impact thresholds are exceeded:

- Bank: greater than 50 linear feet.
- BLSF: greater than 5,000 square feet.
- LUWBW: great than 5,000 square feet.
- Riverfront Area: greater than 5,000 square feet.

The need for a wildlife habitat evaluation will be determined during design once the areas that will be disturbed are better defined.

7.3.2 Water Quality Certification

Under Section 401 of the federal Clean Water Act, a Water Quality Certification (WQC) is required for certain activities proposing discharges to water bodies or wetlands. This regulatory program is implemented by the individual states – in this case the MADEP. The program gives states the authority to review projects that must

obtain federal permits and that result in a discharge to state waters, including excavating and placement of fill in wetlands. The purpose of the State 401 review is to ensure that a project will comply with state water quality standards and other appropriate requirements of state law. Regulatory authority for the certification is found in 314 CMR 9.00.

The impact thresholds of the 401 WQC program have largely been coordinated with the WPA regulations. As a result, smaller projects approved by municipal conservation commissions under the WPA generally do not need further state review under the 401 program. These projects are automatically certified when they obtain an Order of Conditions. However, some types of projects with potentially large wetland impacts require an individual certification by MADEP.

A 401 Certification must be obtained for any project that results in filling or excavating in bordering vegetated wetlands, and that is also subject to regulation by the U.S. Army Corps or Engineers, Federal Energy Regulatory Commission, or other federal agency.

There are two categories of water quality certification which concern discharge, fill, and excavation projects: Major Fill and Excavation Project Certification (BRP WW 10) and Minor Fill and Excavation Project Certification (BRP WW 11). A Major Fill/Excavation Project Certification (BRP WW 10) is required for projects involving excavation or filling of more than 5,000 square feet of bordering and isolated vegetated wetland and land under water, while a Minor Fill/Excavation Project Certification (BRP WW 11) is required for projects involving excavation or filling of up to 5,000 square feet of bordering and isolated vegetated wetlands and land under water. For projects involving less than 5,000 square feet of impacts to Bordering Vegetated Wetlands, the Order of Conditions received from the local Conservation Commission serves as the WQC, and a separate WQC submittal to MADEP is not required. Exceptions to this rule include but are not limited to work in rare species habitat or Outstanding Resource Waters. The BRP WW 10 permit application (for a Major Fill/Excavation Project Certification) has a State review period of up to 150 days from the date of submission while the BRP WW 11 permit application (for a Minor Fill and Excavation Project Certification) has a review period of up to 120 days from the date of submission.

The wetland impacts are not expected to exceed 5,000 square feet, based on the sewer extension alternatives developed.

7.3.3 Sewer Extension Permit

In accordance with 314 CMR 7:00, Sewer System Extension and Connection Program, any modification to an existing sewer system requires a permit from MADEP. This permit application must be filed at least 150 days prior to the date of when the sewer

construction is to commence. In general, the application must describe the location of the extension, type of piping system to be used, the design capacity of the proposed extension, the estimated flow to be collected by the proposed extension, the type of wastewater to be collected, and the ultimate treatment point for the wastewater and the availability of capacity at that facility. A Sewer Extension Permit will be required for the preferred alternative, regardless of which alternative is selected.

7.3.4 Massachusetts Environmental Policy Act (MEPA)

The Massachusetts Environmental Policy Act (MEPA – M.G.L. Chapter 30, Section 61-62H) requires applicants of proposed projects to study the potential environmental consequences of their proposed project, and take measures to avoid, minimize and mitigate damage to the environment.

MEPA applies to projects that exceed certain thresholds outlined in their regulations and that also require a permit from a state agency. The MEPA review process is not a permitting process, but rather a public review process intended to act as a "clearing house" for public agencies. The MEPA process is administered through the Executive Office of Environmental Affairs (EOEA) and regulatory authority for the MEPA process is under 301 CMR 11.00.

MEPA review is required for a project if impact thresholds are triggered for a number of separate categories:

- Land;
- Rare Species;
- Wetlands, Waterways and Tidelands;
- Water;
- Wastewater;
- Transportation;
- Energy;
- Air;
- Solid and Hazardous Waste;
- Historical and Archaeological Resources;

- Areas of Critical Environmental Concern; and
- Regulations.

Under the category of wastewater, the review threshold for an ENF and an EIR is the construction of 10 miles or more of new sewers for the collection of wastewater. Because this Project includes the construction of 24± miles of sewers, both an ENF and an EIR will be required.

Further, the MEPA regulations do not allow for construction of a wastewater project without the project first receiving approval of a Comprehensive Wastewater Management Plan (CWMP) by MADEP. Since the Town of Barnstable's CWMP has not yet been approved, a request for a waiver to construct this Project must be filed with the EOEA, if the project is to proceed to construction prior to completion of the CWMP.

7.3.5 Massachusetts Department of the State Secretary (M.G.L. Chapter 9, Sections 26-27D)

No state permit from any other agency will be valid before the Massachusetts Historical Commission (MHC) is consulted to determine potential impacts on any historical or archaeological resources. Notification of the project impacts will be sent to MHC during the MEPA review process. MHC will review the project and make a determination as to whether it may or may not have any impacts on significant State cultural, historic, or archaeological assets.

As was noted previously, the MHC has been contacted to determine if any historic, cultural, or archaeological features will be impacted by the proposed work. The MHC has indicated that there are three recorded historical archaeological sites and one recorded ancient Native American site within the project area. In addition, the MHC has indicated that the project area is archaeologically sensitive and likely to contain additional archaeological sites and historic resources, although the project area has not been systematically surveyed by professional archaeologists.

7.3.6 Massachusetts Endangered Species Act (M.G.L. Chapter 131A)

No state permit from any other agency will be valid before the Massachusetts Division of Fisheries and Wildlife, Natural Heritage and Endangered Species Program (NHESP) is consulted to determine potential impacts on state-listed rare species. Notification will be sent to the NHESP describing the potential project impacts during the MEPA review process. The 2000-2001 Massachusetts Natural Heritage Atlas indicates that Priority Habitats of Rare Species are located across the entire area surrounding Lake Wequaquet, Bearse Pond and Shallow Pond. In addition, Estimated Habitats of Rare

Wildlife and Certified Vernal Pools are located north of Bearse Pond and east of Lake Wequaquet. All construction-related activities for the project will be included as part of the ENF and, as such, will be subject to NHESP review.

The Massachusetts Division of Fisheries and Wildlife, Natural Heritage and Endangered Species Program has been contacted to determine the species of concern in order to better understand if the rare species or priority habitats will be impacted by the proposed work. The NHESP has indicated that the following species in the project area are of concern:

Table 7-1
Species of Concern

Common Name	Taxon	Status
Comet Darter	Dragonfly	Special Concern
Wright's Panic-Grass	Plant	Special Concern
Bushy Rockrose	Plant	Special Concern
Redroot	Plant	Special Concern
Sandplain Flax	Plant	Special Concern
Pondshore Knotweed	Plant	Special Concern
Papillose Nut-Sedge	Plant	Endangered
Torrey's Beak-Sedge	Plant	Endangered
Plymouth Gentian	Plant	Special Concern
Terete Arrowhead	Plant	Special Concern
Water-Willow Stem Borer	Butterfly	Threatened
Plymouth Gentian	Plant	Special Concern

7.3.7 Massachusetts Highway Department

The Massachusetts Highway Department (MHD) requires that a permit be obtained for any work performed in the right-of-ways under their jurisdiction. This permit is to ensure that any work performed in the right-of way does not have any negative effects on the integrity and therefore the safety, presently provided by the Highway in question.

A force main, which would serve the Lake Wequaquet area and the Cape Cod Community College, is proposed on Route 132, which is a state highway. In addition, new sewers are proposed on Route 28, which is also a state highway. Therefore, a MHD permit must be obtained for the construction of this project. Once the

preliminary design of the sewers on Route 28 and Route 132 is complete, it will be presented to the MHD to obtain their early input. This will help reduce the overall review time for the Project by the Department.

7.4 REGIONAL REVIEW PROGRAMS

The Cape Cod Commission (CCC) is a regional planning agency that reviews and provides input on the design, construction and operation of new development/construction projects on Cape Cod. The purpose of the Cape Cod Commission is to further:

1. the conservation and preservation of natural, undeveloped areas, wildlife, flora and habitats for endangered species;
2. the preservation of coastal resources including aquaculture;
3. the protection of groundwater, surface water and ocean water quality, as well as the other natural resources of Cape Cod;
4. balanced economic growth;
5. the provision of adequate capital facilities, including transportation, water supply, and solid, sanitary and hazardous waste disposal facilities;
6. the coordination of the provision of adequate capital facilities with the achievement of other goals;
7. the development of an adequate supply of fair affordable housing; and
8. the preservation of historical, cultural, archaeological, architectural, and recreational values.

The CCC requires that a project proponent develop and submit a report that describes the environmental impacts that the project may have on the Region. This report and subsequent permit application, which is referred to as a Development of Regional Impact (DRI), will also detail the possible measures that will be taken to mitigate the environmental impacts identified. The CCC permitting process and the MEPA Process are usually undertaken in a joint process referred to as a "Major and Complicated Project" review. As in the MEPA process, this process will involve several public hearings and meetings with the Commission and a public information process.

7.5 LOCAL TOWN PERMITS

7.5.1 Street Opening Permits

The Town of Barnstable requires that a permit be obtained for any work performed in Town Streets - this is known as a Street Opening Permit. This permit is issued by the Engineering Division of the Barnstable Department of Public Works. A Street Opening Permit will be required for this project since the majority of the new sewers will be constructed within roadways.

7.5.2 Barnstable Conservation Commission

In conjunction with the MADEP WPA, described above, the Town of Barnstable also has its own Wetlands Protection Bylaw (Chapter III, Article XXVII). Application for a permit under this ordinance will be made in conjunction with the application for the MADEP NOI. The municipal wetlands bylaw is more stringent than the WPA in two noteworthy areas:

1. Abutter notification is required to residents within 300 feet of the lot where the wetlands have been disturbed instead of 100 feet.

2. A 50-foot "no disturb" zone is established within the WPA 100-foot Buffer Zone. In cases where the slope of the Buffer Zone exceeds 18%, the Commission has the discretion to increase the width of the "no disturb" zone beyond 50 feet.

7.6 SUMMARY OF PERMITS

Table 7-2 provides a summary of the permits discussed previously in this report section.

Table 7-2
Summary of Project Permits Anticipated

Reviewing Authority	Agency	Permit or Review Required	Threshold
Federal	U.S. EPA	NPDES General Stormwater Permit	Construction Project greater than 5 Acres
	Wampanoagan Tribal Historic Preservation Officer	Tribal Resources review and comment	Any work within areas that may contain historic or archaeological resources
	U.S. Army Corps of Engineers	Programmatic General Permit [1]	>5,000 sq. feet of wetland impacts

Table 7-2

Summary of Project Permits Anticipated

Reviewing Authority	Agency	Permit or Review Required	Threshold
	U.S. Fish & Wildlife Service	Rare species review and consultation	Any work within the vicinity of federally-listed rare species habitat
State	Massachusetts Department of Environmental Protection	Sewer Extension Permit	Any modification to an existing sewer system
	Massachusetts Department of Environmental Protection	401 Water Quality Certification	5,000 sf to 1 acre wetland impact, discharges of fill to rare species habitat, Outstanding Resource Waters, etc.
	Massachusetts Highway Department	Construction Permit	Any work within Mass Highway right of way
	MA Division of Fisheries and Wildlife, NHESP	Rare Species review and consultation	Work within estimated habitat of State-listed rare species
	MA Historical Commission	Historic and archaeological features review and consultation	Any work within areas that may contain historic or archaeological resources
	Massachusetts Environmental Policy Act Unit (EOEA)	Environmental Impact Report Certifications (Draft and Final)	Construction of 10 or more miles of new sewers
	Massachusetts Environmental Policy Act Unit (EOEA)	Waiver for Construction	Construction of a MEPA project without an approved EIR
Regional	Cape Cod Commission	Development of Regional Impact	Same as that for a EIR
Local	Barnstable Conservation Commission	Order of Conditions	Construction within a Resource Area or within 100 feet of a Resource Area
	Barnstable Department of Public works	Street opening permit	Construction within a Town roadway

Notes: (1) Only if wetland resource areas are determined to meet the jurisdictional criteria of "Waters of the United States" per 33 CFR 328.

8.1 TRAFFIC IMPACT ROUTE ASSESSMENT

As described previously, the proposed project is located in central Barnstable and encompasses the properties surrounding Wequaquet Lake and Long Pond, generally south of Route 6 and Route 132, north of Pine Street, West of Phinney's Lane and Wequaquet Lane and east of Shootflying Hill Road. The project also includes the installation of a force main in the Route 132 Right-of Way (ROW), under Route 6, from Cape Cod Community College to the Route 132/Bearses Way intersection.

In order to provide sewer service to this diverse area, construction will be required within roadway ROW's of all different classifications. The construction will include the installation of sewer lines along the roadways for the most part. However, there are also numerous ROW crossings (including the Route 6 on-ramps and off-ramps), the installation of individual property lateral connections, and pump stations.

The roadways affected by the construction can be classified in the following categories:

1. Major Arterials (State Routes)
   - Route 132 – 30,000-40,000 Average Daily Traffic (ADT), south of Rte 6
   - Route 28 (Falmouth Road) - 30,000 ADT
2. Minor Arterials (Town Roads)
   - Phinney's Lane - 15,000 ADT
   - West Main Street - 15,000 ADT
3. Collectors
   - Shootflying Hill Road - 6,000 ADT
   - Great Marsh Road - 6,000 ADT
4. Local Residential
   - Thru Roads
   - Dead Ends

5. Driveways
    - Single
    - Shared

Each roadway, whether it is to have a sewer installed along it or across it, will be classified and appropriate maintenance and protection of traffic procedures will be assigned to it. Access to all adjoining properties, commercial and residential, will be maintained during construction. A comprehensive traffic plan will be outlined during the Final Design phase.

8.2 TRAFFIC OPERATIONS

With the objective of maintaining acceptable traffic operations on all affected roadways, each street will be inventoried for:

1. Roadway width
2. ROW width
3. Location of proposed sewer lines within those widths
4. Roadway operation
    - one-way versus two-way
    - number of lanes
5. Intersection control
6. Traffic volumes
7. Traffic speeds
8. Ownership (State, Town, or private)

Once each street is inventoried, it will be assigned the appropriate classification associated with the proper maintenance and protection of traffic procedures.

8.3 TRAFFIC SAFETY

8.3.1 Traffic Control During Construction

The guidelines described in the paragraphs that follow will be used to determine where and what type of traffic control patterns to use for various situations. These guidelines will provide for the safe and efficient movement of traffic though work zones and enhance the safety of work forces in the work area.

8.3.2 Traffic Control Patterns

Typical Massachusetts Highway Department traffic control patterns will be used where a work operation requires that all or part of any vehicle or work area protrudes onto any part of a travel lane or shoulder. For each situation, the installation of traffic control devices will be based on the following:

1. Speed and volume of traffic
2. Duration of operation
3. Exposure to hazards

In the case of horizontal or vertical sight restriction in advance of the work area, the traffic control pattern will be extended to provide adequate sight distance for approaching traffic. If a lane reduction taper is required to shift traffic, the entire length of the taper will be installed on a tangent section of roadway so that the motorist can see the entire taper area. Any existing signs that are in conflict with the traffic control patterns will be removed, covered, or turned so that they are not readable by oncoming traffic. When installing a control pattern, a buffer area will be provided. This area will be free of equipment, workers, materials and parked vehicles.

Although the traffic control pattern for each street will be considered individually, conformity with the typical traffic control plans develop during design and generally described here will be provided.

8.3.3 Placement of Signs

Signs will be placed to allow motorists the opportunity to reduce their speed prior to the work area. Signs will be installed on the same side of the roadway as the work area. On multi-lane divided highways, advance warning signs may be installed on both sides of the highway. On directional roadways (on-ramps, off-ramps, one-way roads), where the sight distance to signs is restricted, signs will be installed on both sides of the roadway.

8.4 TRAFFIC SAFETY DISCUSSION

8.4.1 Coordination Meetings

A meeting with local and state department representatives, including fire, police, public works, utility companies, transit operators and transportation departments, will be held to review the pending project. The project scope, layout, schedule and Maintenance and Protection of Traffic (MPT) plans and specifications will be reviewed. Based on questions and concerns expressed at this meeting, a Memorandum of Understanding will be prepared to document items discussed at the meeting and concerns to be addressed during the development of the final MPT Plan.

8.4.2 Work Zone Safety Meetings

Prior to commencement of construction, a work zone safety meeting will be conducted with Representatives of the Massachusetts Highway Department (MHD), the Massachusetts State Police (Local Barracks), the Barnstable Police, the contractor and the Traffic Control subcontractor (if different than the prime contractor) to review the contract requirements and discuss the contract procedures. Other work zone safety meetings during the course of the project will be scheduled as needed.

9.1 GENERAL

The four alternatives developed in detail as part of this evaluation, and described in Section 6, have been compared in this section. These alternatives have been compared with respect to (1) construction costs, operation & maintenance costs, and 50-year life-cycle costs and (2) non-monetary criteria, such as environmental impacts and short-term and long-term neighborhood impacts. This comparison provides the basis for selecting a recommended alternative.

9.2 COSTS

Estimated sewer system expansion costs have been developed for each of the four alternatives developed in detail in this report. These costs are based on the November 2002 Engineering News Record Construction Cost Index (ENR CCI) of 6578. The cost estimates include:

- Construction costs
- Land acquisition costs
- Operation and maintenance (O&M) costs
- Equipment replacement costs

It is important to note that although land acquisition costs have been included in this estimate, land acquisition costs can vary significantly, depending on the value of the property under consideration, and are subject to negotiation with the individual property owners. The land acquisition costs include the purchase of land, legal fees, survey, and the preparation of easement/land taking drawings

The cost components described above were used to develop 50-year life cycle costs for each alternative in order to determine the most cost-effective alternative.

The following cost sources were utilized in this evaluation:

1. Bid prices from recent projects with similar sewerage system components, especially those obtained in the eastern portion of Massachusetts. Note in particular that bid prices from the recent vacuum sewer projects in Barnstable and Provincetown were used for this evaluation. A complete list of bid references is included in Section 14.

2. Estimated costs provided by manufacturer's representatives were used to supplement the bid prices. In particular, AIRVAC and Roediger provided cost

estimates for vacuum sewer system components and E/One and Meyers provided cost estimates for low pressure sewer system components.

3. RSMeans construction cost data, which is a commonly used source of cost information, was used to check bid prices and to determine costs for special construction activity, such as sheeting and dewatering.

9.2.1 Construction Costs

The construction costs include the following general components, which are listed in the detailed construction cost summaries included in Appendix C:

Gravity Sewers

- Gravity sewer piping (main line pipe and service laterals to property line)
- Manholes
- Pump stations
- Force Mains
- Odor control equipment

Low Pressure Sewers

- Low pressure sewer piping (main line pipe and service laterals to property line)
- Grinder pumps
- Air release manholes
- Cleanout manholes
- Odor control equipment and related facilities

Vacuum Sewers

- Vacuum sewer piping (main line pipe and service laterals to property line)
- Valve pit
- Vacuum stations
- Force mains
- Buffer tanks

Each item includes the cost of materials, installation, testing, mobilzation/demobilization, and the contractor's overhead and profit. The piping unit costs vary depending on the depth of construction anticipated. Where low pressure sewers are proposed, we have assumed that there would be a grinder pump for each house, rather than a grinder pump station serving two or more houses. Similarly, where vacuum sewers are proposed, we have assumed that there would be a valve pit for each house, rather than a valve pit serving two or more houses.

The construction costs include the cost of the new sewerage system components proposed within the AOC, infrastructure costs from the AOC to the existing system connection point, and the cost of improvements needed to the existing sewerage system. Each alternative includes the cost to replace the Main Street pump station with a new pumping facility and the cost to redirect the pump station force main to the nearby Old Colony Road pump station force main.

The cost of odor control equipment, a building, if needed, and odor control chemicals (calcium nitrate) have been included in the cost estimates. Odor control equipment is recommended at the Sub-Area 3 pump station, under Alternatives 1, 3, and 4, and the Sub-Area 3A pump station, under Alternative 2, in order to prevent odors generation within the 6,500-foot long force main from these pump stations.

Odor control equipment is also recommended in the pump station proposed under Alternative 3 to serve the low pressure sewers in Sub-Areas 5, 6, and 7. Similarly, a chemical feed facility is recommended under Alternative 4 to provide odor control for the low pressure sewers in Sub-Area 5. This odor control facility would be a small, unheated building constructed near the upstream end of Sub-Area 5 to house the chemical storage and feed equipment.

In addition to the sewerage system components listed above, where special construction conditions exist, they were also considered in evaluating the construction costs for each alternative. For example, the deep sewers proposed on Huckins Neck Road for Alternative 1 are expected to be difficult to construct because of the high groundwater conditions in this area. In order to account for these difficult construction conditions, an additional cost for sheeting and dewatering the deep sewers in this area was included in the cost estimate. Similarly, many of the pump stations proposed are expected to require deep construction and the cost of constructing a cofferdam and dewatering the building site was included in the construction cost for these pumping facilities.

The construction costs developed for Alternatives 1 through 4 include the cost of the grinder pumps. However, because there is the potential that the homeowners will purchase, own, and maintain the grinder pumps, construction costs have also been developed for alternatives that exclude grinder pump costs. These alternatives are referred to in this report as Alternatives 1A, 2A, 3A and 4A.

The construction costs for Alternatives 1, 2, 3 and 4 range from $17.8 million to $21.4 million and the construction costs for Alternatives 1A, 2A, 3A and 4A range from $13.3 million to $18.7 million, as shown in Table 9-1. Note that the construction costs for Alternatives 1, 2 and 4 were similar and only varied by approximately 4%. Similarly, the construction costs for Alternatives 1A, 2A, and 4A also varied by only 4%. For each alternative, a 20% construction contingency has been added to the cost of the new infrastructure and to the cost of upgrading the existing sewer system on West Main Street to accommodate the wastewater flow from the Long Pond area, as is described in Section 6. However, a construction contingency was not added to the grinder pump construction costs since there is less potential for variability in these costs or unforeseen conditions that could impact these costs.

Note that the construction costs developed do not include:

1. house service connections between the building and the street line, other than the cost of the grinder pump unit or vacuum valve pit, where required;
2. police for traffic control;
3. engineering design services, or
4. engineering services to monitor construction activity.

Several enhancements to a typical grinder pump unit can be provided and are listed below in Table 9-2. These enhancement costs have not been included in the construction cost estimates developed.

Table 9-2

Grinder Pump Unit Enhancements

Enhancement	Estimated Cost
Larger sump storage volume	$200-$400 (1) (2)
Generator connection at control panel	$200-$300 (1)
Dialer to send standard high water alarm signal to a remote location (3)	$300
Monitoring of wastewater level, pump run time, number of pump activations and alarm status, which can be sent to a remote location via a modem (3)	$1,000

Notes:

(1) Cost varies, depending on manufacturer.

(2) Sump storage volume would increase to 1.5 to 2 times standard volume.

(3) If remote monitoring is pursued, the grinder pump signals would likely be relayed to the WWTP for review and action, as appropriate.

Table 9-1
Engineer's Opinion of Probable Sewer System Extension Construction Costs
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension Project

Alternative	Total Length of Sewers (lf)	No. of Pump/ Vacuum Stations	No. of Grinder Pumps	Construction Cost				
				New Infrastructure	Upgrades to Existing Sewers	20% Contingency	New Grinder Pumps	Total
Grinder Pumps Purchased by Town								
1	125,500	8 PS's	361	$15,102,000	$512,000	$3,123,000	$2,708,000	$21,445,000
2	129,550	11 PS's	401	$14,555,000	$512,000	$3,013,000	$3,008,000	$21,088,000
3	120,210	5 PS's	598	$10,581,000	$512,000	$2,219,000	$4,485,000	$17,797,000
4	125,400	4 PS's/2 VS's	287	$14,788,000	$512,000	$3,060,000	$2,153,000	$20,513,000
Grinder Pumps Purchased by Residents								
1A	125,500	8 PS's	0	$15,102,000	$512,000	$3,123,000	$0	$18,737,000
2A	129,550	11 PS's	0	$14,555,000	$512,000	$3,013,000	$0	$18,080,000
3A	120,210	5 PS's	0	$10,581,000	$512,000	$2,219,000	$0	$13,312,000
4A	125,400	4 PS's/2 VS's	0	$14,788,000	$512,000	$3,060,000	$0	$18,360,000

9.2.2 Operation and Maintenance Costs

The annual operation and maintenance (O&M) costs that would be incurred have been estimated for each of the alternatives and include the following components:

- Labor costs to maintain the sewer system and operate and maintain the pump/vacuum stations (including grinder pumps and vacuum valves)
- Pump/vacuum station and grinder pump electricity costs
- Chemical addition costs for odor control
- General O&M costs for the pump stations, vacuum stations, grinder pumps, and odor control equipment
- Sewer maintenance costs

For the purposes of this evaluation, we have assumed that it would require a two-person, full-time maintenance crew complete with generator-equipped service truck to operate and maintain the new sewers and pumping facilities proposed under Alternatives 3 and 4. A labor cost of $50,000/year/person was assumed, which includes typical benefit add-ons. The labor costs under Alternatives 1 and 2 were estimated to be less than those for Alternatives 3 and 4, primarily because there are fewer grinder pumps/vacuum valves. For Alternative 1, only one additional full-time person is expected to be necessary while for Alternative 2, one full-time person and one person working 8 hours per week to maintain the proposed sewerage system are expected to be needed. For Alternatives 1A, 2A, 3A, and 4A, which assume that the grinder pumps will be maintained by the residents, the additional labor that would be required by the Town has been reduced to one person working 20 hours per week.

Annual electricity costs were estimated for each alternative based on estimated power consumption for the pump stations, vacuum stations, and grinder pumps. Power consumption was estimated for the pump/vacuum stations by calculating pump sizes and estimating pump run times, based on average daily flow projections. An electricity use unit cost of $0.11/kilowatt-hour, which is currently being charged to the Town wastewater treatment facility, was used to calculate annual electricity costs for each pump/vacuum station.

Annual grinder pump electricity costs were also calculated for Alternatives 1, 2, 3 and 4. Grinder pump electricity costs were based on a flow rate of 11 gpm, an average annual run time of approximately 100 hours per pump, and a electricity use unit cost of $0.11/kilowatt-hour. The average annual estimated electricity cost to operate a grinder pump is $10-$20/year.

Odor control is expected to be needed in some areas, as discussed previously. Chemical addition to control odors, using calcium nitrate, has been proposed in this evaluation, although a more detailed review of available odor control chemicals will be

performed during design. The annual cost to purchase the amount of calcium nitrate that is projected to be needed for each alternative has been calculated by multiplying the annual quantity needed by the unit cost for this chemical, which has been provided by a calcium nitrate supplier.

General equipment O&M costs were also considered for the pump stations, vacuum stations, grinder pumps and chemical feed facilities and were estimated as 3% of the equipment construction costs. General O&M includes the periodic replacement of parts and lubrication over the life of the facilities.

Sewer maintenance costs were included in the O&M costs for each alternative and include:

- Periodic inspection and cleaning of the sewer lines
- Repair/rehabilitation of pipe sections

The estimated annual O&M costs for each of the categories described above are summarized in Table 9-3. Note that the O&M costs did not vary significantly among alternatives for each of the categories, with the exception of chemical addition. Chemical addition is estimated to be more expensive for Alternative 3 because of the need to control odors within the more extensive low pressure system proposed under this alternative.

Table 9-3

Summary of Annual O&M Costs

Alternative No.	Labor [1]	Electricity	Chemical Addition	General Equipment O&M	Sewer Maintenance	Total
Grinder Pumps Maintained by Town						
1	$ 55,000	$5,800	$12,600	$46,400	$62,700	$ 182,500
2	$ 65,000	$7,400	$12,600	$55,400	$64,800	$ 205,200
3	$ 105,000	$6,400	$55,400	$54,100	$60,100	$ 281,000
4	$ 105,000	$5,800	$21,800	$39,700	$62,700	$ 235,000
Grinder Pumps Maintained by Residents						
1A	$25,000	$2,800	$12,600	$24,800	$62,800	$128,000
2A	$25,000	$4,100	$12,600	$31,500	$64,800	$138,000
3A	$25,000	$1,100	$55,400	$18,500	$60,100	$160,100
4A	$25,000	$3,100	$21,800	$22,600	$62,700	$135,200

Notes:

(1) Includes cost of generator-equipped service truck - $5,000/year.

9.2.3 Life Cycle Costs

Once the construction costs and annual O&M costs were determined, they were used to determine life cycle costs for each alternative. The life cycle costs provide a comprehensive summary of the total costs anticipated over the life of the new sewers. We consider the life cycle cost comparison to be the most appropriate method of determining which alternative is most cost-effective. A 50-year period was determined to be the most appropriate life cycle period for this analysis since several components of the proposed work have 50-year design lives, including the proposed piping, pump station structures, and vacuum station structures.

As part of the life cycle cost comparison, all future capital and O&M costs have been converted to present worth costs so that all costs are on an equal time basis, for each alternative. The total present worth cost is commonly referred to as the Net Present Value (NPV). In this evaluation, the NPVs have been categorized as construction NPVs or O&M NPVs. The construction NPVs include the installed construction costs and the equipment replacement costs over the 50-year period. For the pump stations, vacuum stations, and chemical feed facilities, the major equipment is expected to require replacement every 25 years, or twice over the 50-year life cycle period. In comparison, the grinder pump equipment is expected to require replacement every 10 years or five times over the 50-year life cycle period and the vacuum system control valves are expected to require replacement every 15 years or 3 times over the 50-year life cycle period. The current EPA discount rate of 5.88% and an inflation rate of 2.33% were used to determine the Net Present Values of the projected capital costs for each alternative. The capital cost inflation rate was determined by calculating the annual average change in the Engineering News Record Construction Cost Index (ENR CCI) over the past 5 years. The ENR CCI reflects the current cost of construction and is typically used to determine the change in construction costs over time. The O&M NPVs were calculated using the same current EPA discount rate of 5.88% and an inflation rate of 2.42%. The O&M cost inflation rate was determined by calculating the change in the Consumer price Index (CPI) in the northeast over the past 5 years. The CPI reflects the price of goods and services and is typically used to determine the change in the price of these goods and services over time, similar to the ENR CCI.

The total NPV cost for each alternative is calculated as the sum of the NPV capital cost and the NPV O&M cost. The NPV costs are summarized in Table 9-4.

Table 9-4
Summary of Net Present Value (NPV) Costs

Alternative No.	NPV Construction Costs	NPV O&M Costs	Total NPV Costs
Grinder Pumps Purchased and Maintained by Town			
1	$22,274,000	$4,380,000	$26,654,000
2	$22,222,000	$4,924,000	$27,146,000
3	$19,602,000	$6,744,000	$26,346,000
4	$21,731,000	$5,639,000	$27,370,000
Grinder Pumps Purchased and Maintained by Residents			
1A	$18,299,000	$3,072,000	$21,371,000
2A	$17,807,000	$3,311,000	$21,118,000
3A	$13,017,000	$3,841,000	$16,858,000
4A	$18,570,000	$3,243,000	$22,813,000

The life-cycle analysis illustrates that the NPV construction cost, which ranges from $13.0 million to $22.3 million, is a much more significant component than the NPV O&M cost, which ranges from $3.2 to $6.7 million. Alternative 3A provides the lowest total NPV cost, at $16.9 million.

9.3 NON-MONETARY EVALUATION CRITERIA

In addition to the cost of the sewer system expansion alternatives, other criteria are also important in evaluating and comparing alternatives and were considered in this evaluation. The non-monetary evaluation criteria considered include:

- environmental impacts,
- neighborhood impacts,
- reliability, and
- expandability.

Each of these non-monetary factors is discussed in the paragraphs that follow. The four alternatives have been assigned a ranking value from 1 to 5 in each of these categories with lower values indicating that the alternative is less favorable in the category of concern and higher numbers indicating that the alternative is more favorable in the category of concern. At the end of this section, an average non-monetary rank is presented for each alternative, for comparison purposes.

9.3.1 Environmental Impacts

The following categories were considered in evaluating the potential environmental impacts of the proposed project and anticipated mitigation measures:

- water quality,
- wetlands,
- rare species and wildlife, and
- historic and archaeological resources.

The environmental impacts within each category were compared and ranked in the paragraphs that follow for the four sewer extension alternatives considered in order to determine an overall environmental impact ranking for each alternative. The ranking approach is described at the beginning of Section 9.3.

9.3.1.1 Water Quality

Previous evaluations identified high nutrient loadings to Lake Wequaquet and Long Pond from septic systems within the AOC, which can negatively impact water quality. Each of the sewer extension alternatives would improve water quality within Lake Wequaquet, Bearse Pond, Shallow Pond, and Long Pond by eliminating septic systems within the AOC. Similarly, each of the sewer extension alternatives would improve groundwater quality by eliminating the septic systems within the AOC. Note that the northern and eastern portions of the AOC are of special concern because they have been delineated as State approved Zone II groundwater protection areas, as shown in Figure 9-1. These areas are within the recharge area of the Town's sole source aquifer.

There is the potential for short-term negative water quality impacts during construction, primarily related to soil erosion. These water quality impacts will be minimized under each alternative through the use of haybales, siltation fencing, and soil stabilization, where determined to be necessary. The Storm Water Management Plan (SWMP), which is required as part of the Stormwater Phase I permitting process, will require that the construction contractor provide adequate controls to prevent soil erosion and other pollutants from reaching the surface water bodies. In addition, appropriate dewatering procedures will be established in the SWMP to prevent the uncontrolled discharge of groundwater during dewatering operations to a nearby surface water body.

The potential for short-term negative water quality impacts during construction due to erosion are greater for those alternatives that require deeper excavation, since there will be larger disturbed areas (a wider trench is normally needed), a greater amount of trench dewatering, and a greater amount of excavated material stockpiled during the

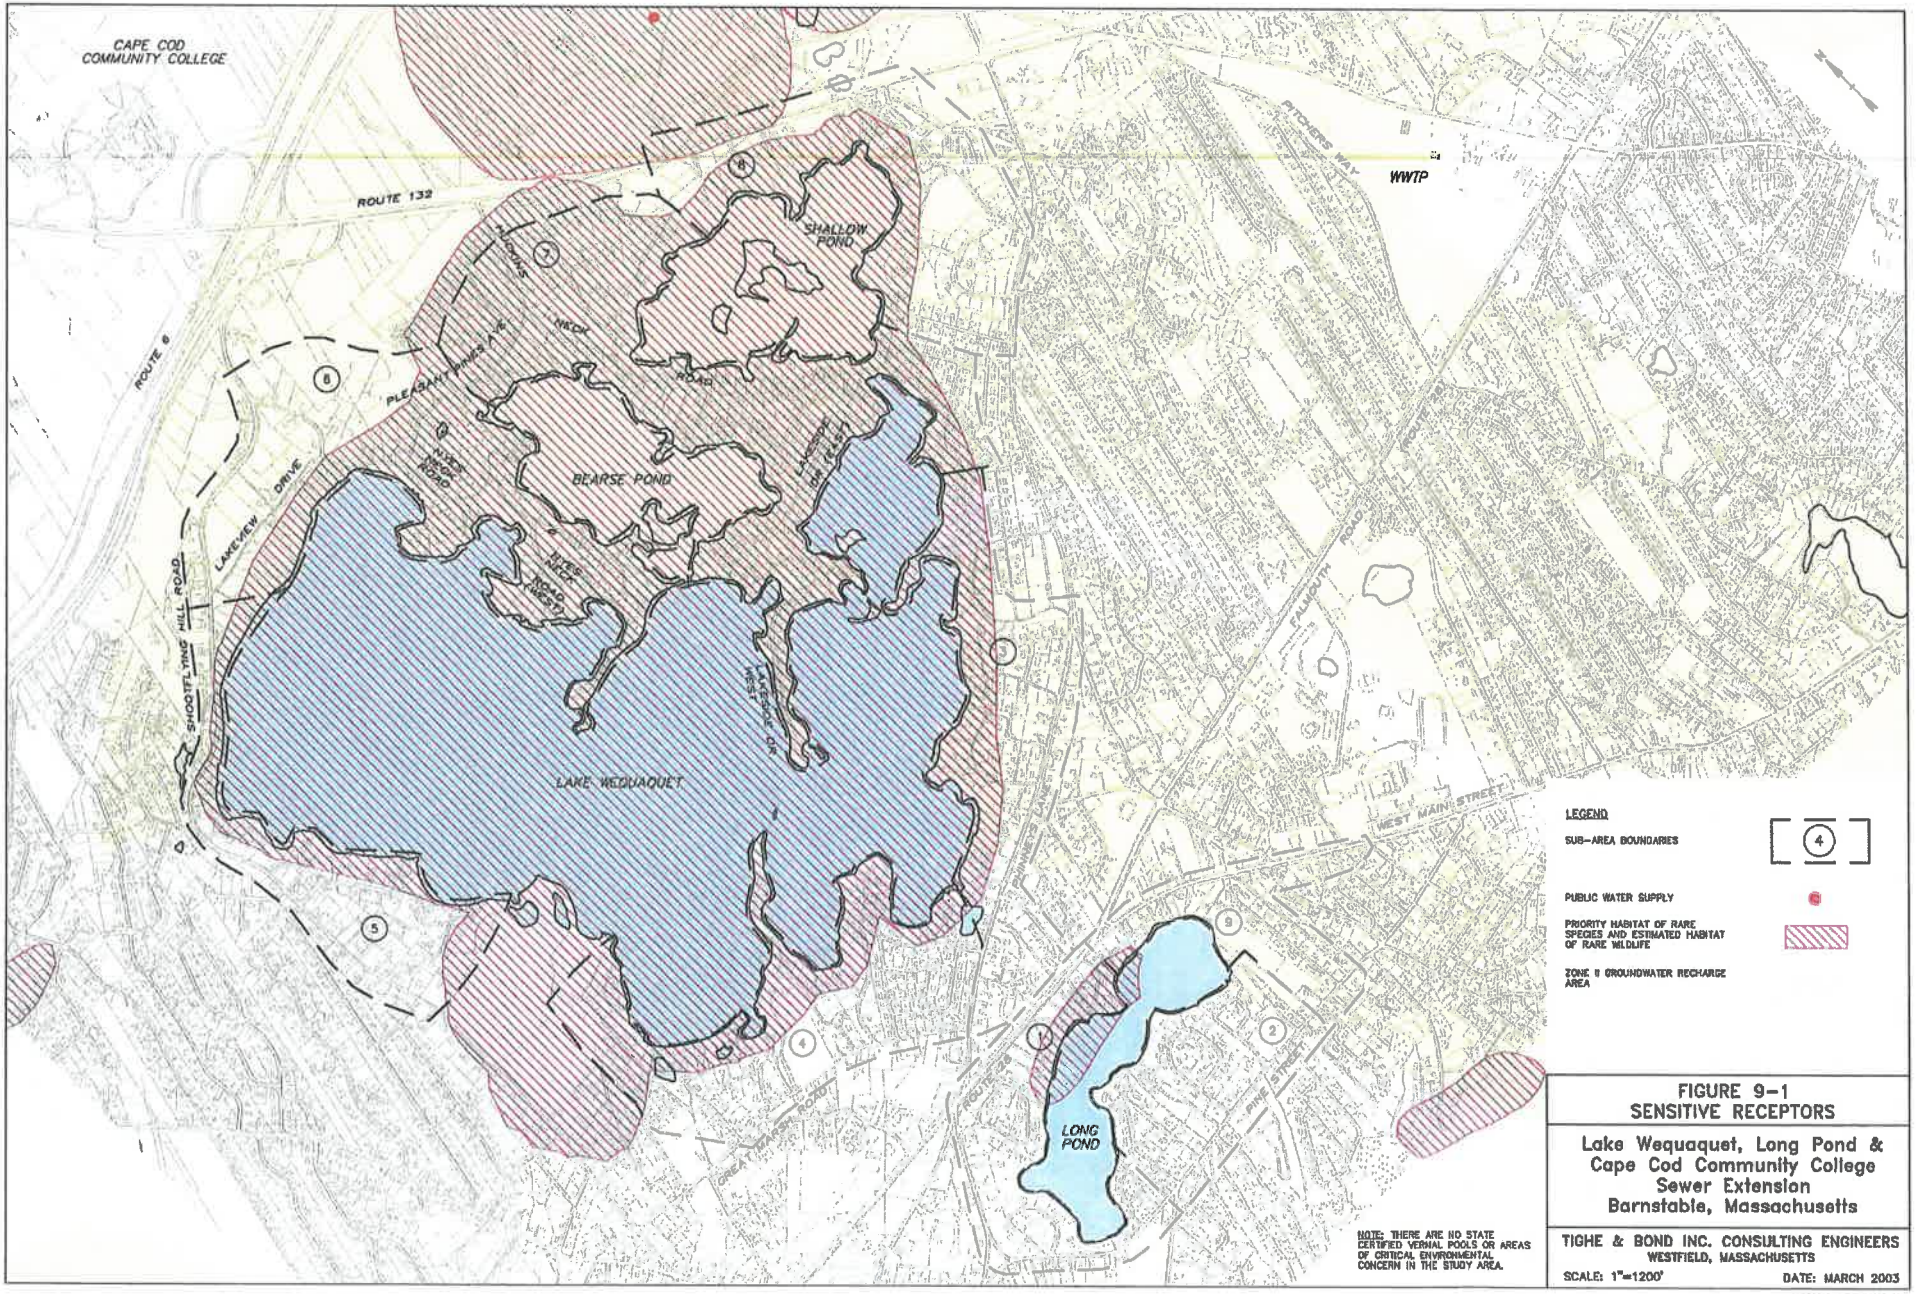

FIGURE 9-1

WESTFIELD, MASSACHUSETTS

SCALE: 1"=1200'

DATE: MARCH 2003

course of construction activity. A summary of the sewer lengths by depth for each alternative is presented in Table 9-5. Alternative 1 requires the greatest amount of deep excavation and, as such, would have a larger potential for short-term negative water quality impacts during construction.

Table 9-5
Sewer Lengths Summary

Sewer Type	Alternative 1 Lengths (ft)	Alternative 2 Lengths (ft)	Alternative 3 Lengths (ft)	Alternative 4 Lengths (ft)
Gravity				
<10 ft. deep	37,530	38,790	18,890	18,890
10-<15 ft. deep	18,720	17,810	9,470	9,470
15-<20 ft. deep	9,240	4,380	5,770	5,770
20-25 ft. deep	2,760	0	2,110	2,110
Subtotal	**68,250**	**60,980**	**36,240**	**36,240**
Low Pressure	30,250	37,520	62,820	28,540
Vacuum	0	0	0	34,370
Force Main	27,000	31,050	21,150	26,250
Total	**125,500**	**129,550**	**120,210**	**125,400**

The potential for short-term negative water quality impacts are also greater for the alternatives with more pump stations since, in most cases, deep excavation is required and the disturbed area is relatively large, in comparison to a pipe trench. In addition, in many cases significant groundwater control will be necessary for the pumping facilities. Table 9-6 presents the number of pumps stations proposed for each of the alternatives and the anticipated excavation depths and structure depths below average groundwater levels. Pump station excavation depths range from 16 feet to 34 feet and were generally deeper under Alternative 1. More pump stations are provided under Alternative 2 in order to reduce the pipe and pump station excavation that would be required under Alternative 1, as is shown in Table 9-6. As a result, less groundwater control would be necessary under Alternative 2 at several pump station sites, in comparison to Alternative 1, although groundwater control would be necessary at more sites. Alternative 3, which requires the fewest pump stations (5), has the lowest potential for water quality impacts related to pump station construction.

As noted previously, each of the sewer extension alternatives would improve water quality within Lake Wequaquet, Bearse Pond, Shallow Pond, and Long Pond. Temporary negative water quality impacts, primarily related to soil erosion, will be minimized during construction for each of the four alternatives considered through

Table 9-6
Pump/Vacuum Station Groundwater Impacts Summary
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

Pump/ Vacuum Station	Alternative 1 (8 PS's)		Alternative 2 (11 PS's)		Alternative 3 (5 PS's)		Alternative 4 (4 PS's/2 VS's)	
	Excavation Depth (ft)	Structure Depth Below Groundwater (ft)	Excavation Depth (ft)	Structure Depth Below Groundwater (ft)	Excavation Depth (ft)	Structure Depth Below Groundwater (ft)	Excavation Depth (ft)	Structure Depth Below Groundwater (ft)
1	18	13	18	13	18	13	18	13
2	26	14	26	14	26	14	26	14
3/3A	30	22	18	10	30	22	30	22
3B	---	---	22	16	---	---	---	---
4	25	19	25	19	25	19	25	19
5	21	11	21	11	---	---	---	---
6	23	17	23	17	---	---	16	10
7	34	17	---	---	16	Above GW level	16	Above GW level
7A	---	---	18	8	---	---	---	---
7B	---	---	18	10	---	---	---	---
7C	---	---	19	12	---	---	---	---
8	18	3	18	3	---	---	---	---
Average	24	15	21	12	23	17	22	16

Notes:

(1) Groundwater levels were determined using 1986 USGS groundwater resources mapping, based on the average elevation of the groundwater table from 1963 to 1976. This data was confirmed using more recent, but less comrehensive groundwater contour information developed in June, 1992 by Gehrety & Miller through modeling.

appropriate erosion control measures, although Alternatives 1 and 2 have the greatest potential for negative water quality impacts during construction. Conversely, Alternative 3 is least likely to negatively impact water quality because of its shallower pipe installation depths and fewer pump stations. Each alternative is ranked in this sub-category in Table 9-7, included at the end of Section 9.3.1.

9.3.1.2 Wetlands

Wetland resource areas are present throughout the AOC, including especially the Nyes Neck area, as shown in Figure 7-1. The majority of the proposed sewers will be constructed within existing roadways and will not impact nearby wetland areas, assuming that standard good construction practices are employed, including proper placement of haybales and siltation fences, and appropriate dewatering methodologies.

However, the proposed sewers and pump stations will be constructed within the 100-foot wetlands buffer zone under each alternative. Five areas were identified as being of particular concern and are listed below:

- On the south side of Phinney's Lane, just west of Tellegen Trail, in Sub-Area 3. A pump station is proposed near this wetland area as part of sewer extension Alternative 2, detailed in Section 6.

- At the northerly corner of the intersection of Huckins Neck Road and Cottonwood Lane, in Sub-Area 7. A pump station is proposed at this location under Alternative 2, near a drainage channel between Shallow Pond and Lake Wequaquet and within the 100-foot Buffer Zone of the Banks of Shallow Pond and Lake Wequaquet.

- On the south side of Pleasant Pines Avenue, just east of Nyes Neck Road, in Sub-Area 6. A pump station or vacuum station is proposed in this area under Alternatives 1, 2 and 4, and is within 100 feet of a Bordering Vegetated Wetland just south of the pump station site.

- On the south side of Shoot Flying Hill Road, just south of Lakeview Drive and on the Town beach in Sub-Area 5. A pump station is proposed at this location under Alternatives 1 and 2. The pump station is within the 100-foot Buffer Zone of the Bank of Lake Wequaquet.

- On the north side of Lake Drive, on the Wequaquet Lake Association beach in Sub-Area 4. A pump station is proposed at this location under each of the four alternatives. The pump station will likely be within the 100-foot Buffer Zone of the Bank of Lake Wequaquet.

Alternative 2 has the greatest potential for wetland impacts since pump stations would be constructed near the five wetland sites listed above as being of concern. In comparison, Alternative 1 would require construction at three of the sites identified above as being of concern, Alternative 4 would require construction at two of the sites identified above as being of concern, and Alternative 3 would require construction at one of the sites listed above as being of concern.

As noted previously, wetland impacts will be minimized during construction for each of the four alternatives considered through appropriate erosion control measures, although Alternative 2 has the greatest potential to impact wetlands during construction. Alternative 3 has the lowest potential to impact wetlands during construction and is ranked highest in this sub-category. Each alternative is ranked in this sub-category in Table 9-7, included at the end of Section 9.3.1.

9.3.1.3 Rare Species and Wildlife Habitats

The Massachusetts Division of Fisheries and Wildlife has determined Priority Habitats of Rare Species and Estimated Habitats of Rare Wildlife in Massachusetts through the Natural Heritage and Endangered Species Program (NHESP). These areas have been mapped in the most recently published (2000-2001) Massachusetts Natural Heritage Atlas. Priority habitats of rare species have been identified within and along the banks of Lake Wequaquet, Bearse Pond and Shallow Pond, and along the northern banks of Long Pond, as shown in Figure 9-1. In addition, estimated habitats of rare wildlife were identified just north of Bearse Pond and west of Lake Wequaquet, in the area of Lewis Point. The NHESP has indicated that several rare species are present in the AOC.These species are listed in Table 7-1.

Because the majority of the proposed work will be in existing roadways, significant impacts to these habitats are not anticipated. However, because the pump/vacuum stations proposed for each of the alternatives will be located off of the roadways, they are of greater concern. The following pump/vacuum stations are near the Priority Habitats of Rare Species and Estimated Habitats of Rare Wildlife identified and have the greatest potential for impacting these habitats:

- Alternative 1 – Pump Stations 4, 5, 6 and 7
- Alternative 2 – Pump Stations 4, 5, 6, 7A, 7B, and 7C
- Alternative 3 – Pump Station 4
- Alternative 4 – Pump Station 4 and Vacuum Stations 6 and 7

Alternative 2 has the greatest potential to impact rare species and wildlife habitats and is ranked lowest in this sub-category, while Alternative 3 has the least potential to impact rare species and wildlife habitats and is ranked highest in this sub-category.

Each alternative is ranked in this sub-category in Table 9-7, included at the end of Section 9.3.1.

9.3.1.4 Historic and Archaeological Resources

The Massachusetts Historical Commission (MHC) has been contacted to identify locations within the AOC of historic or archaeological significance. The MHC has indicated that there are three recorded historical archaeological sites and one recorded ancient Native American site within the project area. In addition, the MHC has indicated that the project area is archaeologically sensitive and likely to contain additional archaeological sites and historic resources, although the project area has not been systematically surveyed by professional archaeologists.

Since the majority of work will be in existing roadways, the historical/archaeological impacts are expected to be minimal under each of the proposed alternatives. However, because the pump/vacuum stations proposed for each of the alternatives will be located off of the roadways, they are more likely to have impacts on historic/archaeological resources. As such, alternatives that require a greater number of pump/vacuum stations are expected to have a greater potential for impacts to historic/archaeological resources.

9.3.1.5 Summary

The alternatives developed have been ranked with respect to each environmental category and then averaged in order to develop an overall ranking for environmental impacts, as shown below in Table 9-7.

Alternative 3 is ranked highest in the category of environmental impacts because it has the smallest impact on water quality, wetlands, and rare species and wildlife habitats, and the lowest potential for impacts to historic/archaeological resources. The environmental impacts rankings, along with the rankings for the other non-monetary criteria reviewed, are summarized in Table 9-13, included at the end of Section 9.3.

Table 9-7
Environmental Impacts Overall Ranking

Sub-Category	Ranking			
	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Water Quality	1	2	4	3
Wetlands	2	1	4	3
Rare Species and Wildlife	3	1	5	4
Historic and Archaeological Resources	3	2	5	4
Average	**2.3**	**1.5**	**4.5**	**3.5**

9.3.2 Neighborhood Impacts

The following categories were considered in evaluating the potential neighborhood impacts of the proposed project and anticipated mitigation measures:

- aesthetics,
- traffic,
- noise,
- air quality, and
- land acquisition.

9.3.2.1 Aesthetics

The majority of the components of the proposed sewer extension alternatives (piping, valves, manholes, grinder pump packages, air valves pits, etc.) would be below grade and are not expected to have a significant aesthetic impact on the residents within the AOC. However, above-grade pumping/vacuum facilities will be needed under each sewer extension alternative and are expected to have an aesthetic impact on the residents within the AOC. Although below-grade submersible pump stations could be provided, we anticipate that a standby generator to provide emergency power in the event of a power failure will be required at each of the pump stations and vacuum stations. As such, an above-grade enclosure would be provided or a building would be constructed at each facility to house the generator and pump station controls. The extent to which the pumping/vacuum stations will have an impact on residents within the AOC depends on the proximity of these facilities to residences, the degree to which these facilities can be hidden from view, and the appearance of these facilities. In addition, note that a chemical feed facility to control odors is proposed in Sub-Area 5. This facility would be a small, unheated building to house a chemical storage tank, chemical feed pumps, and pump controls. This facility will be sited during design.

Based on input provided by Town officials, we have assumed, for the purposes of this evaluation, that a building will be provided for each pump station to house the standby generator, pump controls, instrumentation, and pump station equipment. In addition, we anticipate that the pump station/vacuum station buildings will be designed with architectural features similar to the buildings in the surrounding area in order to blend in with the neighborhood appearance, to the extent practical. Architectural features that will be considered during design include roofing material and type (flat vs. pitched) and building façade (brick, cedar clapboard, vinyl-sided, concrete, etc.).

The pump/vacuum station sites have been described in Section 6 and each facility's potential aesthetic impact on residences within the AOC is categorized in Table 9-8 as minor, moderate, or high, depending on its location with respect to nearby residents. Subsequently, this information was used to establish a ranking for each alternative. Each alternative is ranked in this sub-category in Table 9-10, included at the end of Section 9.3.2.

Table 9-8
Aesthetic Impacts Summary

Pump/Vacuum Station	Alternative 1	Alternative 2	Alternative 3	Alternative 4
1	high	high	high	high
2	moderate	moderate	moderate	moderate
3/3A	moderate	moderate	moderate	moderate
3B	---	minor	---	---
4	high	high	high	high
5	high	high	---	---
6	minor	minor	---	minor
7	moderate	---	---	moderate
7A	---	minor	---	---
7B	---	minor	---	---
7C	---	moderate	---	---
5-7			minor	
8	minor	minor	---	---
Total High	3	3	2	2
Total Moderate	3	3	2	3
Total Minor	2	5	1	1

Pump/vacuum stations that would be constructed in public areas, such as parks and beaches, were considered to have a "high" impact on area residents. The Sub-Area 1 pump station, which would be constructed in Mother's Park for each of the alternatives, falls into this category. Similarly, the Sub-Area 4 pump station would be constructed on the Wequaquet Lake Association beach located off of Lake Drive for each of the alternatives and is expected to have a "high" aesthetic impact. In addition, a pump station is proposed under Alternatives 1 and 2 on the Town beach off of Shootflying Hill Road in Sub-Area 5 and would also have a "high" aesthetic impact.

The pump/vacuum stations that are proposed on private property but that are either a significant distance away from the nearby homes or buffered from view were considered to have a "minor" aesthetic impact. The pump/vacuum stations that are proposed on private property but that are relatively close to nearby houses and are not buffered from view were considered to have a "moderate" aesthetic impact.

Alternative 2, which has the greatest number of pump stations, is ranked lowest in this sub-category, while Alternative 3, which has the fewest number of pump stations, is ranked highest in this category.

9.3.2.2 Traffic

The proposed project will not generate any new traffic except during construction. Therefore, the traffic impacts will be temporary and traffic control concerns will be reviewed during the public information process with Town residents that might be impacted. Traffic impacts should be limited to short and temporary detours around construction for short periods of time.

The alternatives that require longer construction durations within the existing roadways will have greater traffic impacts. Construction will be slower where deeper sewers or more pump stations are proposed. A summary of the sewer lengths by depth is shown in Table 9-4 and the number of pump stations for each alternative is shown in Table 9-5. Alternatives 1 and 2 are expected to require a longer period to construct because of the deeper sewer construction required and the greater number of pump stations, in comparison to Alternatives 3 and 4. Alternative 4 would require one more pump station than alternative 3 and, as such, is ranked slightly lower. In addition, Alternative 3 is ranked highest because it requires the least total quantity of new piping, which would also contribute to a shorter construction duration.

Each alternative is ranked in this sub-category in Table 9-10, included at the end of Section 9.3.2.

9.3.2.3 Noise

Heavy machinery, such as trucks, loaders, backhoes, etc., will be needed during construction to excavate pipe trenches, grade work areas, and replace disturbed pavement. In addition, pumps will be needed periodically to dewater trenches. The operation of this equipment will generate noise greater than is typically experienced in the residential areas within the AOC. However, these noise impacts will be short-term, lasting only as long as the construction activity within a particular area. In order to minimize noise impacts during construction, the contractor will be limited to specific hours of the day established prior to construction and with the input of Town officials and neighborhood residents.

Similar to traffic impacts, the alternatives that require longer construction durations will have greater noise impacts. Construction will be slower where deeper sewers or more pump stations are proposed, as noted above. Alternatives 1 and 2 are expected to require a longer period to construct because of the deeper sewer construction required and the greater number of pump stations, in comparison to Alternatives 3 and 4, as discussed under traffic impacts.

Each alternative is ranked in this sub-category in Table 9-10, included at the end of Section 9.3.2, and is similar to the ranking for traffic impacts.

9.3.2.4 Air Quality

Short-term air quality impacts may be experienced due to dust generation during construction. Construction-related dust can typically be effectively controlled using calcium chloride or water, as appropriate.

Similar to traffic and noise impacts, the alternatives that require longer construction durations will have greater air quality impacts related to dust generation. Construction will be slower where deeper sewers or more pump stations are proposed, as noted above. Alternatives 1 and 2 are expected to require a longer period to construct because of the deeper sewer construction required and the greater number of pump stations, in comparison to Alternatives 3 and 4.

The generation of sewage odors is a concern when constructing sewage collection systems, especially in the following areas:

1. In vacuum stations, where odors are of particular concern since substantial quantities of air are drawn from the collection system into the station. Air removal equipment, such as carbon filters or biofilters, is typically recommended.

2. In pump station wetwells, where substantial quantities of wastewater are stored.

3. In pipelines with long detention times, such as long force mains or low pressure sewers.

For the purposes of this preliminary design evaluation, odor control equipment has been proposed for the Sub-Area 3 pump station under Alternatives 1, 3 and 4 and for the Sub-Area 3A pump station under Alternative 2, since these pump stations would have a relatively long force main. In addition, this pump station receives wastewater flow from an upstream pump station in Sub-Area 4, increasing the potential for septic conditions to occur, which can lead to odors.

As noted above, sewage odors are also concern where there are long low pressure sewers, resulting in long sewage detention times in the piping. This is even more of a concern in areas such as Barnstable that have seasonal fluctuations in population, which can result in even longer sewage detention times when the summer population leaves the area for the winter. Odor control equipment is proposed in the pump station serving Sub-Areas 5, 6, and 7 under Alternative 3 since long lengths of low pressure sewer will be installed in these sub-areas under this alternative. Similarly, an odor control facility is proposed in Sub-Area 5 under Alternative 4 since long lengths of low pressure sewers will be installed in this sub-area under this alternative.

Appropriate measures will be taken to control dust during construction and sewage odors after the sewer extension construction has been completed. However, for the purposes of this evaluation, the alternatives have been ranked with respect to their potential to impact air quality. The potential for sewage odors is considered to be a more significant air quality concern than the potential for dust during construction. As such, the alternatives with a greater potential for sewage odors were ranked lower than alternatives with a greater potential for dust generation.

Alternative 4 is ranked lowest in this sub-category because it requires odor control equipment at one pump station, two vacuum stations and at a separate odor control facility in Sub-Area 5. Alternative 3, which requires odor control equipment at two pumping facilities, is also ranked relatively low in this sub-category. Alternatives 1 and 2 only require odor control equipment at one pump station and are ranked highest in this sub-category.

Each alternative is ranked in this sub-category in Table 9-10, included at the end of Section 9.3.2.

9.3.2.5 Land Acquisition

Each of the alternatives considered requires the purchase of land for the construction of pump/vacuum stations on private property or the purchase of land rights for sewer easements on private property. In addition, Alternative 4 will likely require the purchase of land for an odor control facility in Sub-Area 5. Although most of the sewers will be constructed within the existing roadways under each alternative, many of the streets within the AOC are privately owned. The Town will need to obtain easements on these streets to construct the proposed sewers and then, once installed, to maintain them. The sewer locations are essentially the same under each alternative and will require that the same easements be obtained, regardless of the alternative pursued.

There are locations off of the existing roadways and on private property where pump/vacuum stations are proposed under each alternative. In each case, a small plot of land (on the order of 2,500 square feet) would need to be purchased to construct the

proposed facilities, with sufficient space to park a maintenance vehicle and remove equipment. A summary of the pump/vacuum stations required under each alternative and whether they are proposed on private property is presented in Table 9-9.

Table 9-9
Pump/Vacuum Station Site Property Information

Pump/Vacuum Station	Property Owner			
	Alternative 1	Alternative 2	Alternative 3	Alternative 4
1	Town of Barnstable (1)	Town of Barnstable (1)	Town of Barnstable (1)	Town of Barnstable (1)
2	Privately Owned (2)	Privately Owned (2)	Privately Owned (2)	Privately Owned (2)
3/3A	Privately Owned	Privately Owned	Privately Owned	Privately Owned
3B	---	Privately Owned (2)	---	---
4	Wequaquet Estates Beach Association (3)	Wequaquet Estates Beach Association (3)	Wequaquet Estates Beach Association (3)	Wequaquet Estates Beach Association (3)
5	Town of Barnstable (4)	Town of Barnstable (4)	---	(5)
6	MA Division of Fisheries & Wildlife (2)	MA Division of Fisheries & Wildlife (2)	---	MA Division of Fisheries & Wildlife (2)
7	Privately Owned	---	---	Privately Owned
7A	---	Privately Owned	---	---
7B	---	Privately Owned	---	---
7C	---	Privately Owned	---	---
5-7	---	---	Nstar Electric Company (2)	---
8	Privately Owned	Privately Owned	---	---
No. of Land Acquisitions Required	6	9	4	6

Notes:

(1) Mother's Park

(2) Open lot

(3) Wequaquet Beach Association beach

(4) Town beach

(5) A chemical feed facility for odor control is expected to be needed in this Sub-Area but has not yet been sited.

Land acquisitions are important since they increase the cost of sewer system expansion; can impact the sewer system expansion schedule, depending on the length of time

required to negotiate an agreement; and can result in the Town pursuing the purchase of land on other properties if an agreement with a homeowner can not be reached.

Alternative 3 would require the fewest number of land acquisitions and is most favored in this sub-category. Alternative 2 would require the greatest number of land acquisitions and is least favored in this sub-category. The alternatives developed have been ranked with respect to land acquisition in Table 9-10, included at the end of Section 9.3.2.

9.3.2.6 Summary

The alternatives developed have been ranked with respect to each of the neighborhood impact categories described above. These individual rankings have been averaged in order to develop an overall ranking for neighborhood impacts, as shown below in Table 9-10.

Table 9-10
Neighborhood Impacts Overall Ranking

Sub-Category	Ranking			
	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Aesthetics	2	1	4	3
Traffic	2	2	4	3
Noise	2	2	4	3
Air Quality	4	4	3	1
Land Acquisition	3	1	5	3
Average	2.6	2.0	4.0	2.6

Alternative 3 is ranked highest in the category of neighborhood impacts because it has the smallest impact on aesthetics, noise, and traffic and requires the acquisition of the fewest properties for the construction of new sewerage system facilities. The neighborhood impacts rankings, along with the rankings for the other non-monetary criteria reviewed, are summarized in Table 9-13 included at the end of Section 9.3.

9.3.3 Reliability

An important consideration in evaluating alternatives is the expected reliability of the proposed sewer system. Generally, alternatives that require more mechanical equipment, such as pumps, for their operation are considered less reliable since mechanical equipment can more readily fail than pipes, especially if not properly operated and maintained. This is not expected to be a significant concern for the proposed pump/vacuum stations in Barnstable since each facility will be equipped with

a standby pump that can be used in the event of a pump failure and a standby generator that can be used in the event of a power failure.

Individual homeowner grinder pumps are not typically provided with standby power and, although there is some storage provided within the grinder pump pits, during a prolonged power outage there is the potential for sewage backups into house service lines. In addition, individual homeowner grinder pump units are typically not provided with standby pumps. As such, if a grinder pump fails, there will not be service to that house until the pump is repaired or replaced. Downtime can be minimized with early detection of problems (visual and audible alarms) and proper stocking of spare parts. However, because of these concerns, alternatives that include a greater number of grinder pumps are considered less reliable.

Reliability is also a concern for the vacuum sewers because a significant leak in the collection system, caused by a pipe break, will impact the operation of the entire vacuum sewer system tributary to the vacuum station. A system leak could result in sewage backups if not quickly identified and corrected. Because a leak can affect a relatively large area, it may be difficult to locate. Because of this concern, alternatives that include a greater amount of vacuum sewers are also considered less reliable.

The alternatives developed have been ranked with respect to reliability below in Table 9-11.

Table 9-11
Reliability Ranking

Alternative No.	Ranking
1	5
2	4
3	3
4	3

9.3.4 Expandability

With proper planning, gravity sewers and pumping stations can be designed to accommodate both current wastewater flows and projected future wastewater flows in the AOC. Similarly, vacuum sewers and vacuum stations can be designed to accommodate both current wastewater flows and projected future wastewater flows in the AOC. In comparison, low pressure sewers are sized based on a specific range of flows and cannot accommodate substantial flow increases, as discussed in Section 6. If there is a substantial increase in flows in an area where low pressure sewers are installed, a second pipe may be necessary. As such, low pressure sewer systems can not readily accommodate significant sewer system expansion.

Alternative 3, which includes the construction of the greatest amount of low pressure sewers, is least favored under this category. Note in particular that the low pressure sewers proposed within the AOC along Shootflying Hill Road under Alternative 3 would not be able to accommodate the full build-out flows projected within the relatively large Bowl area to the west.

The alternatives developed have been ranked with respect to expandability below in Table 9-12.

Table 9-12
Expandability Ranking

Alternative No.	Ranking
1	4
2	4
3	3
4	4

9.3.5 Summary of Non-Monetary Criteria

The four sewer extension alternatives developed have been ranked in each of the categories described previously in this report section and listed below:

- environmental impacts,
- neighborhood impacts,
- reliability, and
- expandability.

The rankings in each category for each alternative are presented in Table 9-13. The alternatives were ranked from 1 to 5 for the non-monetary criteria with 1 being the least favorable and 5 being the most favorable, as described previously.

Table 9-13

Non-Monetary Criteria Ranking Summary

Sub-Category	Ranking			
	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Environmental Impacts	2.3	1.5	4.5	3.5
Neighborhood Impacts	2.6	2.0	4.0	2.6
Reliability	5.0	4.0	3.0	3.0
expandability	4.0	4.0	3.0	4.0
Average	**3.5**	**2.9**	**3.9**	**3.3**

Alternative 3 provides the highest overall ranking, primarily because it has the lowest potential for environmental and neighborhood impacts. However, it is important to note that there is only a small variation in overall ranking among the four alternatives.

Generally, the alternatives with a greater amount of gravity sewers (Alternatives 1 and 2) had greater environmental and neighborhood impacts, primarily as a result of the need for more pump stations and the longer construction duration anticipated. However, Alternatives 1 and 2 are considered more reliable and can readily accommodate future expansion.

The opposite is true for Alternative 3, which includes the greatest amount of low pressure sewers. The environmental and neighborhood impacts are expected to be least significant but the low pressure sewers are considered less reliable and can not readily accommodate future expansion.

Alternative 4, which includes a significant amount of vacuum sewers, is expected to have a lower environmental impact than Alternatives 1 and 2 but a higher neighborhood impact than Alternative 3. Similar to Alternative 3, there are some reliability concerns associated with Alternative 4, although it can readily accommodate future growth, if properly designed.

SECTION 10 FIELD AND UTILITY SURVEY AND MAPPING

10.1 GENERAL

Information on existing underground utilities within the areas to be sewered was collected as part of this evaluation. This information will be used during design to adjust the layout of the preferred sewer layout, as necessary, to minimize conflicts during construction. The following utility companies were contacted and provided information on their utilities in the AOC:

Utility Company	Buried Utility
Barnstable Dept. of Public Works	Drainage
Massachusetts Highway Department	Drainage
Centerville-Osterville-Marstons Mills Water Department	Water
Barnstable Water Company	Water
Barnstable Fire District	Water
Keyspan Energy Delivery	Gas
NSTAR Electric	Electric
Verizon	Telephone
Comcast	Cable

Information on the utilities listed above and their potential impact on the recommended sewer extension alternative are described in the paragraphs that follow.

10.2 DRAINAGE

Plans and GIS mapping of existing drainage systems within portions of the AOC were obtained from the Town. In addition, the Massachusetts Highway Department (MHD) provided plans showing the location of drainage piping and structures on Route 132 and Route 28 as well as older plans for Phinney's Lane and Shootflying Hill Road. The plans and GIS mapping were supplemented by field investigations of the existing drainage system within the AOC. More detailed information on the drainage system within the AOC, including pipe depths, will be obtained during the field verification phase scheduled during design, as part of the overall field survey that will be performed.

Two specific drainage conduits were identified as being of concern during a review of the drainage system. The first is a 72± inch diameter corrugated metal pipe (CMP) drain that conveys flow from the cranberry bogs north of Pleasant Pines Avenue, across Pleasant Pines Avenue, to Lake Wequaquet. The drain invert is 8 to 9 feet below road

grade with 2 to 3 feet of cover over the pipe. As such, the proposed piping on Pleasant Pines Avenue would need to have an invert elevation that is about 11 feet below grade at the location of this drainage pipe. In comparison, the current gravity sewer layouts for Alternatives 1 and 2 show a sewer invert elevation between 8 and 10 feet below grade at this location. The preferred sewer extension alternative will be adjusted as necessary during design to avoid conflicts with this drainage pipe, once the drain pipe size and depth has been confirmed through field survey.

In addition, there are two 48± inch diameter culverts crossing Pine Street that convey water away from Long Pond, which were identified as being of concern. The drain inverts are approximately 8 feet below road grade with about 4 feet of cover over the pipe. As such, the proposed piping on Pine Street would need to have an invert elevation that is about 10 feet below grade at the location of these drainage pipes. In comparison, for the four alternatives described in Section 6, the gravity sewers at this location have invert elevations between 8 and 10 feet below grade. The preferred sewer extension alternative will be adjusted as necessary during design to avoid conflicts with these drainage pipes, once the drain pipe sizes and depths has been confirmed through field survey.

10.3 WATER

The AOC is served by three separate and independent water companies: the Centerville-Osterville-Marstons Mills (C-O-M-M) Water Department, the Barnstable Water Company, and the Barnstable Fire District. The C-O-M-M Water Department services the majority of the AOC except the Nyes Neck Peninsula on Lake Wequaquet, Route 132 south of Route 6, and the Crestview Circle/Regatta Drive development. Route 132, south of Route 6, is served by the Barnstable Fire District while the Crestview Circle/Regatta Drive development is served by the Barnstable Water Company. There is no water service to the Nyes Neck peninsula.

Each of the water companies has provided approximate information on the location of their water mains, valves and hydrants within the AOC, as well as on pipe sizes. However, water main depth information was not provided. Based on common water main construction practices, the majority of the water mains are expected to be about 5 feet below grade. No conflicts with the existing water mains in the AOC that would significantly impact the comparison of alternatives were identified.

10.4 GAS

The AOC is served by Keyspan Energy Delivery, who provided plans of the gas distribution system within the AOC. There is gas service throughout this area, with the exception of the Nyes Neck peninsula.

The records plans provide approximate information on the location of the gas mains within the AOC. Although gas main depth information was not provided, the majority of the gas mains are expected to be less than 5 feet below grade. No conflicts with the existing gas mains in the AOC that would significantly impact the comparison of alternatives were identified.

10.5 ELECTRIC

The AOC is served by NSTAR Electric, who provided schematics of the underground primary electric lines within the AOC. The streets where underground primary electric lines were identified include:

- Route 132, in the area of Phinney's Lane
- Shallow Pond Village
- Crosby Lane
- Phinney's Lane at Crosby Lane
- Hayes Road
- Route 28, near West Main Street
- West Main Street, between Strawberry Hill Road and Old Strawberry Hill Road
- Shootflying Hill Road at High Noon Drive and near Knotty Pines Lane

The schematics provide approximate information on the location of the underground electric conduits within the AOC. Although conduit depth information was not provided, the majority of the underground electrical conduits are expected to be less than 5 feet below grade. No conflicts with the existing electrical conduits in the AOC that would significantly impact the comparison of alternatives were identified.

10.6 TELEPHONE

The AOC is served by Verizon, who provided some plans of the underground telephone lines within the AOC. The plans provided by Verizon show underground telephone on the following streets:

- Shootflying Hill Road, from Lakeview Drive to Route 132
- Route 132, in the area of Phinney's Lane

- Phinney's Lane, near Route 132

The records plans provide approximate information on the location of the underground telephone conduits within the AOC. Although conduit depth information was not provided, the majority of the underground telephone conduits are expected to be less than 5 feet below grade. No conflicts with the existing electrical conduits in the AOC that would significantly impact the comparison of alternatives were identified.

10.7 CABLE

The AOC is served by Comcast, who provided some plans of the underground cable lines within the AOC. The plans provided by Comcast show underground cable on the following streets:

- Route 28, near Phinney's Lane
- Crosby Road
- Indian Trail
- Hayes Road
- Loomis Lane
- Waterview Circle
- Pondside Circle
- Blue Water Drive
- Cottonwood Lane
- Goose Point Road
- Regatta Drive
- Crestview Circle
- Dacey Drive
- Old Strawberry Hill Road, near Route 132
- Shootflying Hill Road, near Lakeview Drive
- Shallow Pond Drive

The records plans provide approximate information on the location, size and material of the underground cable conduits within the AOC. Although conduit depth information was not provided in most cases, the majority of the underground cable conduits are expected to be less than 5 feet below grade. No conflicts with the existing cable conduits in the AOC that would significantly impact the comparison of alternatives were identified.

The geotechnical program for the project, which was originally scheduled for the preliminary design phase, has been deferred until a preferred sewer extension alternative has been selected. This approach allows the Town to tailor the geotechnical program to a specific sewer extension layout and correspondingly to minimize the cost to perform this work.

The geotechnical program consists of the advancement of soil borings and test pits in order to determine:

- soil conditions;
- the presence of ledge; and
- groundwater level.

In order to maintain eligibility for state funding, the geotechnical program must comply with specific criteria established by the MADEP. These criteria include:

1. The advancement of soil borings every 300 feet where new sewers are proposed.
2. The advancement of soil borings a minimum of 50% deeper than the sewer invert.
3. The collection of information on change in soil stratum, soil classification, groundwater level, and blow counts at 5-foot intervals.

12.1 SUMMARY

The Town initiated facilities planning activities in the early 1990s, which are still on-going. The facilities planning effort identified high nutrient loadings to Lake Wequaquet, Bearse Pond, Shallow Pond, and Long Pond, which were negatively impacting water quality. One of the major sources of this high nutrient loading was determined to be septic system discharges. In order to reduce these high nutrient loadings, the Town has implemented this sewer extension project, which will allow the existing septic tanks within the Area of Concern (AOC) established by the Town around Lake Wequaquet and Long Pond to be abandoned.

In addition, this project includes a sewer extension evaluation for Cape Cod Community College, which is currently served by several septic systems. The college is currently designing a pump station to collect and then discharge its wastewater flow into the Town's collection system. The pump station force main route and Town sewerage system connection point has been investigated as part of this evaluation.

Current and projected future wastewater flow estimates for the AOC and the Cape Cod Community College were developed in this report. The wastewater flow projections were used to determine the appropriate size of new sewers needed to serve these areas. For this evaluation, the AOC has been divided into 9 sub-areas and wastewater flows were determined for each sub-area.

Four sewer extension alternatives were developed in detail in this evaluation in order to determine the most economical preliminary sewer extension design, which can be used as the basis for the development of detailed construction contract documents. The alternatives were developed to accommodate full build-out conditions within the AOC, to the extent possible. These alternatives consist of various combinations of three sewer collection system technologies:

- Gravity sewers and pump stations
- Low pressure sewers and grinder pumps
- Vacuum sewers and vacuum stations

The four alternatives were compared with respect to costs and other non-monetary criteria. These alternatives are generally described below and are summarized in Table 12-1.

Alternative 1, shown in Figure 6-6, was developed to maximize the amount of gravity sewers while minimizing the number of conventional pump stations and low pressure

sewers/grinder pumps within the AOC. Alternative 1 consists of a combination of gravity and low pressure sewers.

Alternative 2, shown in Figure 6-15, consists of a combination of gravity and low pressure sewers, similar to Alternative 1. This alternative was developed to reduce the deep excavation that would be required under Alternative 1 on Huckins Neck Road (Sub-Area 7), Phinney's Lane (Sub-Area 3), and Pine Street (Sub-Area 2). Excavation depths exceeding 20 feet would be required in these areas under Alternative 1. With the changes provided by Alternative 2, the excavation depths have been limited to no more that 20 feet. In order to reduce excavation depths, additional pump stations have been proposed on Huckins Neck Road and Phinney's Lane and additional low pressure sewers have been proposed for collector sewers tributary to Phinney's Lane and Pine Street.

Alternative 3, shown in Figure 6-20, was developed to further reduce excavation depths in the northern portion of Lake Wequaquet from that shown for Alternatives 1 and 2 by installing low pressure sewers throughout this area. The southern portion of Lake Wequaquet and the Long Pond area would be served by a combination of gravity and low pressure sewers, similar to Alternative 1.

Alternative 4, shown in Figure 6-22, is similar to Alternative 3 except that Sub-Areas 6 and 7 would be served by vacuum sewers rather than low pressure sewers. These two sub-areas were determined to be the most appropriate for the installation of vacuum sewers because they are relatively flat and there are no large grade changes, which can present problems for vacuum sewers due to vacuum lift limitations.

Table 12-1

Alternatives Summary

Alternative	Total Sewer Length (ft)	Total Gravity Sewer Length (ft)	No. of Pump/Vacuum Stations	No. of Grinder Pumps	No. of Air Valve Pits
1	125,500	68,300	8 PSs	361	---
2	129,500	61,100	11 PSs	401	---
3	120,100	36,300	5 PSs	598	---
4	125,300	36,300	4PSs/2VSs	287	311

Five connection points to the existing sewerage system were considered during this evaluation:

1. Old Strawberry Hill Road sewer
2. Route 28 sewer

3. West Main Street sewer
4. Route 132 sewer
5. Freezer Road pump station force main on Route 132

The freezer Road pump station force main connection has been recommended to serve the areas around Lake Wequaquet while the West Main Street sewer connection has been recommended to serve the areas around Long Pond. Note that in order for the West Main Street sewer connection to serve the project area, improvements to the Main Street pump station and the existing sewer system in this area will be required, at an estimated cost of approximately $512,000. This cost is included in the construction costs presented in Table 12-2 for each alternative.

A detailed cost evaluation was performed, including a comparison of construction costs, operation and maintenance costs, and 50-year life cycle costs for the four alternatives. These costs are presented in Table 12-2.

Table 12-2
Alternative Costs and Non-Monetary Rank

Alternative	Construction Costs [1]	Annual O&M Costs [2]	Life Cycle Costs [3]	Non-Monetary Rank [4]
Grinder Pumps Purchased and Maintained by Town				
1	$21,445,000	$182,500	$26,654,000	3.4
2	$21,088,000	$205,200	$27,146,000	2.8
3	$17,797,000	$281,000	$26,346,000	3.6
4	$20,513,000	$235,000	$27,370,000	3.2
Grinder Pumps Purchased and Maintained by Residents				
1A	$18,737,000	$128,000	$21,371,000	3.4
2A	$18,080,000	$138,000	$21,118,000	2.8
3A	$13,312,000	$160,100	$16,858,000	3.6
4A	$18,360,000	$135,200	$22,813,000	3.2

Notes:

(1) Includes the cost of materials, installation, testing, and the Contractor's overhead and profit. In addition, a 20% contingency has been added to the cost of new infrastructure and the cost to upgrade the existing sewerage system. Refer to Table 9-1 for the development of these costs.

(2) Includes labor costs, electricity costs, chemical costs, general O&M costs, and sewer maintenance costs. Refer to Table 9-3 for the development of these costs.

(3) Includes construction costs, equipment replacement costs, and O&M costs. Refer to Table 9-4 for the development of these costs.

(4) Environmental impacts, neighborhood impacts, reliability, and expandability were considered.

In addition, non-monetary criteria were considered, including environmental impacts (water quality, wetlands, rare species and wildlife, and historic and archaeological resources), neighborhood impacts (aesthetics, traffic, noise, air quality, and land acquisition), reliability, and expandability. The alternatives were ranked from 1 to 5 for each of the non-monetary criteria, with 1 being the least favorable and 5 being the most favorable, and then an average non-monetary rank was calculated. The average non-monetary ranks for the four alternatives are also presented in Table 12-2.

12.2 RECOMMENDATIONS

Alternative 3 (or 3A if the grinder pumps are purchased and maintained by the residents) is recommended. This alternative provides the lowest construction cost and lowest 50-year life cycle cost. In addition, this alternative is the highest ranked in the non-monetary category because it is expected to have the least significant impact on the environment and on the neighborhoods surrounding Lake Wequaquet and Long Pond. However, due to the greater quantity of grinder pumps and associated low pressure sewers, Alternative 3/3A was rated lower in reliability and expandability (outside the AOC) than other alternatives. Reliability concerns were related primarily to the impact on sewer service in the unlikely event of a prolonged power outage. These apparent disadvantages can be mitigated through proper staffing, stocking of spare parts, and the use of portable generators. Expansion outside of the AOC, if and when required, can be achieved with additional infrastructure.

A larger version of the Alternative 3 layout (Figure 6-20) is included in Appendix D.

We recommend that the Town take the following actions in order to proceed with implementation of the proposed sewer extension project:

1. Authorize final design of the project to proceed in order to meet the schedule established for the project to complete design by the summer of 2004.

2. Establish a phased construction approach to the project.

3. Prepare a State Revolving Fund (SRF) Project Evaluation Form (PEF) in order to be placed on the State's priority list for loan funding.

RESIDENT
Lake Wequaquet and Long Pond Area
Town of Barnstable

Re: Sewer Service Layout Questionnaire

Dear Resident:

The Town of Barnstable is currently conducting preliminary engineering studies to provide new sewers in the Lake Wequaquet and Long Pond areas to serve your property. The proposed sewers will be able to serve toilets, sinks and other plumbing fixtures above the street level and may be able to serve basement fixtures at some locations.

Please provide information on your existing septic system and sewer pipe. This information will assist us in providing sewer service to your house and will help us minimize sewer costs and construction impacts.

Your input is important. The information you provide will help us to design sewer service to meet your needs. As such, we request that you fill out the attached questionnaire as completely as possible and return it to:

David Popielarczyk, P.E., Tighe & Bond, Inc., 53 Southampton Road, Westfield, MA 01085

Please complete and return this questionnaire by December 1, 2002, so that we can incorporate your responses into the preliminary engineering report. A self addressed, stamped envelop is included, for your convenience. For more information on this project, visit our website at htt://projects.tighebond.com or call David Popielarczyk at (508) 563-5643.

Very truly yours,

Robert A. Burgmann, P.E.
Town Engineer

TOWN OF BARNSTABLE
SEWER SERVICE LAYOUT QUESTIONNAIRE

NAME _____ ADDRESS _____

1. Please indicate on the attached drawing of your property the location of your current sewer discharge pipe, septic tank, and leachfield.

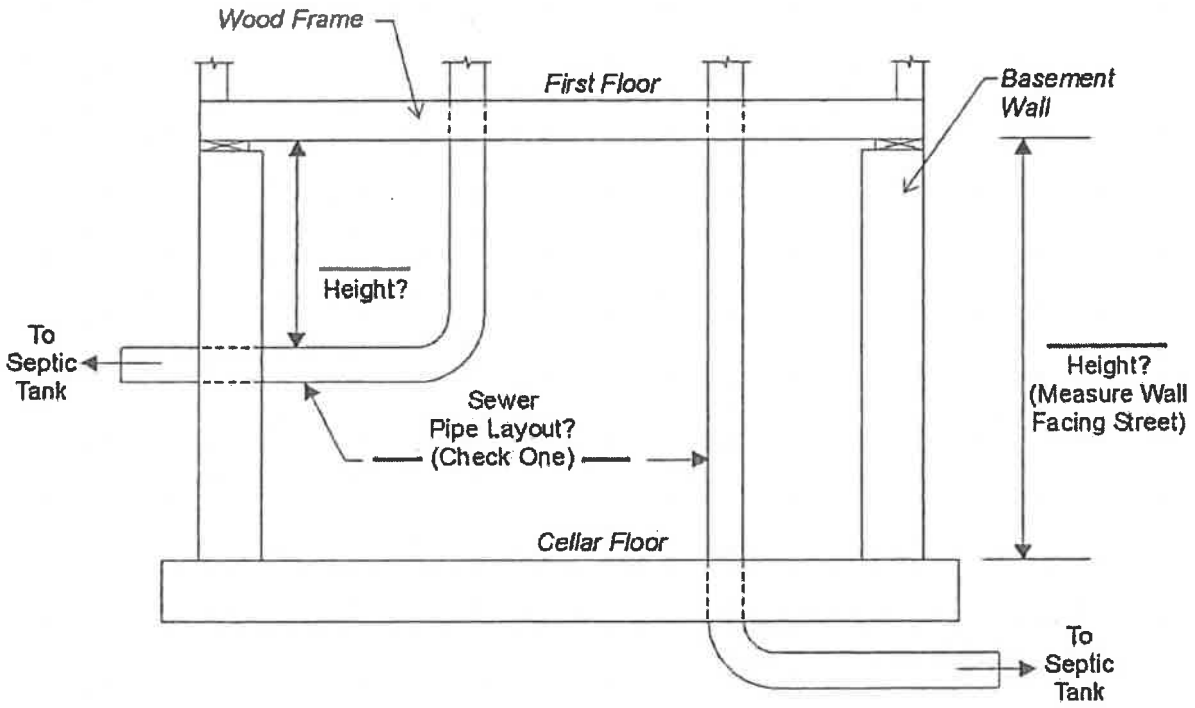
2. Type of home: Cape/Standard _____ Ranch _____ Raised Ranch _____

3. Full Cellar _____ Finished Cellar _____ Crawl Space _____ No Cellar _____

4. Please indicate any plumbing facilities you have in your basement:
   Sink _____ Toilet _____ Bath/Shower _____ Other _____ None _____

5. How does your sewer pipe exit your basement? Through the Wall ____ or Through the Floor ____

6. Please provide the measurements/dimensions requested below:



7. Comments _____

PLEASE COMPLETE AND RETURN THIS FORM TODAY SO THAT WE MAY BETTER SERVE YOU!

Appendix B

House Counts and Wastewater Flows

Notes:

(1) Based on the gravity sewer lengths for Sewer Layout Alternative 1, presented in Section 6.

(2) Calculated as pipe length (in miles) x pipe diameter (in inches) x 350 gpd/in.

(3) Calculated as 2.5 people/house x 72 gpd/person x the number of houses. Both Sub-areas 1 and 7 include a bed & breakfast, which were treated as multi-family homes.

(4) Avg. daily flow calculated as 90% of water usage data and then adjusted to max. month flow based on the peaking factors included in the 1993 Facilities Planning report.

(5) Calculated as the sum of the avg. daily residential sanitary flow rate, the avg. daily commercial sanitary flow rate and the infiltration rate (max. month values).

(6) Calculated as 4 times the average daily sanitary flow plus infiltration.

Table B-2
Summary of Projected Future Wastewater Flows at Full Build-Out (AOC and Bowl)
Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension

LIFE CYCLE COST ANALYSIS SUMMARY SHEET - ALTERNATIVE 1

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	

Base Construction Cost:	$21,444,744
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$1,545,488
Total Capital Cost:	$22,990,232
Total NPV- Capital Cost:	$22,274,286

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$50,000
Total Labor Cost:	$2,500,000
Total O& M Cost/year:	$182,473
Total O & M Cost:	$9,123,630
Total NPV - O & M Costs:	$4,379,538

	Total Cost	NPV
Capital Costs	$22,990,232	$22,274,286
O & M Costs	$9,123,630	$4,379,538
TOTAL:	$32,113,862	$26,653,824

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 1

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$50,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 1

1) **Enter First Year of Capital Spending:** 2004

2) **Using table below, enter project Design Status.** Prelim. Design

Design Status	Miscellaneous Reserve
Prelim. Design	Add 20%
50-75% Design	Add 15%
90-95% Design	Add 10%
100% Design	Add 10%

Houses adjacent to gravity sewers requiring pumping							
	Grinder pumps				$7,500	0	**$0**
Improvements to existing sewerage system							
Replace Main St. Pump Station							$400,000
Divert pumped flow to Old Colony Rd. PS FM		8	1,400		$80		$112,000
Subtotal			**1,400**				**$512,000**
Total			**125,500**				**$15,614,370**

LIFE CYCLE COST ANALYSIS SUMMARY SHEET
ALTERNATIVE 1A - Grinder Pumps Purchased and Maintained by Residents

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	
Base Construction Cost:	$18,737,244
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$828,000
Total Capital Cost:	$19,565,244
Total NPV- Capital Cost:	$18,299,088

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$25,000
Total Labor Cost:	$1,250,000
Total O& M Cost/year:	$128,000
Total O & M Cost:	$6,400,013
Total NPV - O & M Costs:	$3,072,143

	Total Cost	NPV
Capital Costs	$19,565,244	$18,299,088
O & M Costs	$6,400,013	$3,072,143
TOTAL:	$25,965,257	$21,371,231

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 1A - Grinder Pumps Purchased and Maintained by Residents

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$25,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community College Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 1A

1) Enter First Year of Capital Spending: 2004

2) Using table below, enter project Design Status. Prelim. Design

Design Status	Miscellaneous Reserve
Prelim. Design	Add 20%
50-75% Design	Add 15%
90-95% Design	Add 10%
100% Design	Add 10%

LIFE CYCLE COST ANALYSIS SUMMARY SHEET - ALTERNATIVE 2

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	

Base Construction Cost:	$21,087,972
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$1,846,388
Total Capital Cost:	$22,934,360
Total NPV- Capital Cost:	$22,222,262

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$60,000
Total Labor Cost:	$3,000,000
Total O& M Cost/year:	$205,146
Total O & M Cost:	$10,257,315
Total NPV - O & M Co	$4,923,731

	Total Cost	NPV
Capital Costs	$22,934,360	$22,222,262
O & M Costs	$10,257,315	$4,923,731
TOTAL:	$33,191,675	$27,145,993

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 2

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$60,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 2

1) Enter First Year of Capital Spending: 2004

2) Using table below, enter project Design Status. Prelim. Design

Design Status	Miscellaneous Reserve
Prelim. Design	Add 20%
50-75% Design	Add 15%
90-95% Design	Add 10%
100% Design	Add 10%

LIFE CYCLE COST ANALYSIS SUMMARY SHEET - ALTERNATIVE 3

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	
Base Construction Cost:	$17,796,780
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$1,804,125
Total Capital Cost:	$19,600,905
Total NPV- Capital Cost:	$19,601,714

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$100,000
Total Labor Cost:	$5,000,000
Total O& M Cost/year:	$280,985
Total O & M Cost:	$14,049,259
Total NPV - O & M Co	$6,743,945

	Total Cost	NPV
Capital Costs	$19,600,905	$19,601,714
O & M Costs	$14,049,259	$6,743,945
TOTAL:	$33,650,164	$26,345,659

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 3

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$100,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 3

1) Enter First Year of Capital Spending: 2004

2) Using table below, enter project Design Status. Prelim. Design

Design Status	Miscellaneous Reserve
Prelim. Design	Add 20%
50-75% Design	Add 15%
90-95% Design	Add 10%
100% Design	Add 10%

Expected Useful Life

Type of Capital Improvement	Expected Useful Life (in years)
Pump station equip.	25
Grinder pump equip.	10
Pipeline	50
Pump station superstructure	50

Replacement Costs: The analysis will include equipment replacement costs required during the period of the analysis.

Salvage value: Zero salvage values assumed in this analysis

LIFE CYCLE COST ANALYSIS SUMMARY SHEET
ALTERNATIVE 3A - Grinder Pumps Purchased and Maintained by Residents

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	
Base Construction Cost:	$13,311,780
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$615,600
Total Capital Cost:	$13,927,380
Total NPV- Capital Cost:	$13,016,760

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$25,000
Total Labor Cost:	$1,250,000
Total O& M Cost/year:	$160,046
Total O & M Cost:	$8,002,321
Total NPV - O & M Co	$3,841,285

	Total Cost	NPV
Capital Costs	$13,927,380	$13,016,760
O & M Costs	$8,002,321	$3,841,285
TOTAL:	$21,929,701	$16,858,045

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 3A - Grinder Pumps Purchased and Maintained by Residents

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$50,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

LIFE CYCLE COST ANALYSIS SUMMARY SHEET - ALTERNATIVE 4

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	

Base Construction Cost:	$20,512,620
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$1,916,201
Total Capital Cost:	$22,428,821
Total NPV- Capital Cost:	$21,730,510

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$100,000
Total Labor Cost:	$5,000,000
Total O& M Cost/year:	$234,957
Total O & M Cost:	$11,747,844
Total NPV - O & M Co	$5,639,217

	Total Cost	NPV
Capital Costs	$22,428,821	$21,730,510
O & M Costs	$11,747,844	$5,639,217
TOTAL:	$34,176,664	$27,369,727

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 4

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$100,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 4

LIFE CYCLE COST ANALYSIS SUMMARY SHEET - ALTERNATIVE 4A
Grinder Pumps Purchased and Maintained by Residents

Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
Preparer: DJP/DRP
Date: 29-Aug-03

CAPITAL COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.33%
Effective Discount Rate:	3.46%
Terms of Analysis (years)	50
Construction Duration (years):	2
Replacement Cost Period:	
Base Construction Cost:	$18,360,120
Misc. Reserve Prelim. Design	$0
Engineering Cost:	$0
Replacement Capital Cost:	$1,345,788
Total Capital Cost:	$19,705,908
Total NPV- Capital Cost:	$18,570,173

OPERATING COST SUMMARY

Discount Rate:	5.88%
Inflation Rate:	2.42%
Effective Discount Rate:	3.37%
Terms of Analysis:	50
Labor Cost/year:	$25,000
Total Labor Cost:	$1,250,000
Total O& M Cost/year:	$135,134
Total O & M Cost:	$6,756,696
Total NPV - O & M Co	$3,243,359

	Total Cost	NPV
Capital Costs	$19,705,908	$18,570,173
O & M Costs	$6,756,696	$3,243,359
TOTAL:	$26,462,604	$21,813,532

Notes/Assumptions:

ECONOMIC ASSUMPTIONS - ALTERNATIVE 4A - Grinder Pumps Purchased and Maintained by Residents

CAPITAL COSTS:	
*Discount rate:	5.875%
Inflation rate:	2.33%
**Effective Discount rate:	3.46%

OPERATIONS & MAINTENANCE:	
*Discount rate:	5.875%
Inflation rate:	2.42%
**Effective Discount rate:	3.37%

*** Term of analysis:	50 years

Average Salary:	$50,000

NOTE:

* The discount rate reflects the long-term cost of capital.

** The effective discount rate anticipates the effect of the time value of money and inflation by removing inflation from the discount rate.

*** The analysis period for the project is 50 years.

PROJECT INFORMATION

1) Preparer: DJP/DRP
2) Name of Capital Project: Lake Wequaquet, Long Pond and Cape Cod Community Collge Sewer Extension
3) List Assumptions Below:

Input cells are highlighed in light yellow.

CAPITAL COSTS WORKSHEET - ALTERNATIVE 4A

1) Enter First Year of Capital Spending: 2004

2) Using table below, enter project Design Status. Prelim. Design

Design Status	Miscellaneous Reserve
Prelim. Design	Add 20%
50-75% Design	Add 15%
90-95% Design	Add 10%
100% Design	Add 10%

Re: Effluent Mitigation Investigation Project
Task 4 – Cape Cod Community College Investigation
S&W No. 20190.0

Dear Mr. Giordano:

In accordance with your request and the Contract for Consultant Services for the Effluent Mitigation Investigation Project Task 4 – Cape Cod Community College (the College) Characterization, we have completed a preliminary evaluation of the College property off of Route 132 for the recharge of treated effluent. In accordance with paragraph 2.2.5.2 of the Contract for Consultant Services, QA/QC procedures of the Scope of Work were adhered to in the completion of this project. In accordance with paragraph 2.2.5.4 of the Contract, Stearns & Wheler is providing five (5) bound copies, one (1) unbound copy, and one computer copy of this letter report. The evaluation was completed consistent with the Barnstable Wastewater Facilities Plan (WWFP) recommendation to identify and utilize remote sites for the purpose of discharging treated wastewater to the subsurface.

BACKGROUND INFORMATION

The Town of Barnstable is in the process of completing a Wastewater Facilities Plan (WWFP) that evaluates future options for the Town to collect, treat and dispose of municipal wastewater. A component of the WWFP recommended for the identification of parcels of land, remote from the existing Water Pollution Control Facility (WPCF), where treated wastewater can be reclaimed by discharging it back to the subsurface in order to replenish groundwater resources in the Town. Utilization of remote sites was recommended because the WWFP and related work concluded that the recharge capacity of the effluent discharge beds at the existing plant may be limited due to potential adverse impacts related to groundwater mounding. In the course of completing the WWFP, the Town undertook a remote site screening process to identify areas of the Town where suitable parcels may exist. Following the completion of that screening process, the Town

began to identify specific parcels that could be further evaluated for suitability. One of those parcels being investigated is the Cape Cod Community College (College) property. Reference is made to Figure 1 for the location of the College property.

The subject parcel is located at the intersection of Routes 6 and 132 (Exit 6 of the Mid-Cape Highway). Two candidate areas were identified on the property. The first area was located at the athletic field on the north side of the campus. The other area is the wooded area on the northeast side of the college property. The field area was investigated through the installation of one boring and one test pit, and is referred to as Site A. The wooded area was investigated at two different sites located adjacent to the parking areas on the perimeter of the campus. The northerly site investigated is referred to as Site B and the southerly site investigated is referred to as Site C. During discussions between Stearns & Wheler, the College and the Town, it was decided that the stratigraphy of the wooded area could be sufficiently characterized for this screening process without cutting trees, grading and building access roads through the woods. For that reason, the investigation of the wooded site was accomplished with borings and test pits at the woods' edge.

SCOPE OF WORK

The Scope of Work for Task 4 that has been completed for this project is summarized below:

Subtask 4.1 Site Visit. Prior to initiating site work on the site, an initial reconnaissance trip to the site was conducted. Additionally, discussions were held with site representatives. The purpose of these discussions was to determine what restrictions the College might impose that could impact investigative efforts or future use of the site.

Subtask 4.2 Initial Screening. Following the site visit, an initial screening was completed that evaluated the suitability of the site in terms of siting criteria considered in earlier phases of the site identification and screening process, including but not limited to location with respect to:

1. In Wellhead Protection Zones I, II and III
2. In Areas of Critical Environmental Concern
3. Near vernal pools
4. Near wetland
5. In areas of rare and endangered plant and wildlife habitat
6. In conservation areas
7. In flood hazard zones
8. Releases of oil or hazardous materials
9. Drainage basin

Subtask 4.3 Test Pits. Three (3) backhoe test pits were completed at each of three investigation sites. Test pits were excavated to a depth of 8 to10 feet. A soil evaluator logged soil stratigraphy in the test pits. Percolation tests were completed at two of the three test pits. Conditions were not suitable for a percolation test at Site C, because of the presence of boulders and fill material. Test pit locations are shown on Figure 2.

Subtask 4.4 Soil Borings. Three (3) soil borings were drilled. One soil boring was installed in each of the three investigation sites. The proposed work plan specified the borings would be advanced to a depth at least 15 feet below the existing water table. Based on the depth at which the water table was encountered, the borings were advanced to depths of 94, 94, and 84 feet, respectively. Split spoon samples were collected at 5 foot intervals from each boring. Stearns & Wheler recorded soil types on a boring log. Boring locations are shown on Figure 2.

Subtask 4.5 Observation Wells/Slug Tests. Upon completion of the first soil boring, a field determination was made that the site is a likely candidate for effluent discharge, so the soil borings were completed as observation wells. In-situ hydraulic conductivity testing (slug testing) was completed in the two wooded area wells to determine the permeability of the deeper soils. Slug tests were not completed at the athletic field (Site A) because it was determined the soils were not suitable for the placement of discharge facilities because of the presence of boulders and low permeability soil. This data was obtained to support regional mapping data and in order to complete a groundwater mounding analysis, a requirement of a groundwater discharge permit application, should the Town decide it wants to pursue a permit for this parcel.

Subtask 4.6 Report of Findings. A written report for the Town that presents the field investigation results and provides recommendations regarding the use of the subject parcel for treated effluent disposal is included herein.

Subtask 4.7 Meetings. Time was allocated for meetings related to this site investigation. One meeting where preliminary results were presented was held on October 7, 2003. An additional meeting is anticipated.

EVALUATION RESULTS

The results of the Cape Cod Community College investigation are presented in this section. The results are organized in the following order:

- Location Considerations
  - Summary of initial site screening considerations and results.
- Site Characteristics

- Published Information from literature about the general characteristics of the site.

- Field Investigation Results – detailed results from the Stearns & Wheler field investigation.

Location Considerations

Location considerations relate to the suitability of the site based on its setting. These criteria were evaluated by the Town in their initial screening process and included those factors listed in the introduction section of this letter. Stearns & Wheler reviewed and updated these siting criteria.

The results of that screening process indicated that:

1. There are no public water supplies in the immediate vicinity of the College. The College is not in the Zone II of any public water supplies. (See Attachment A Map – Massachusetts GIS Water Supply Protection Area Map).

2. The College is not in an Area of Critical Environmental Concern or in any other designated environmentally sensitive area. (See Attachment B Map – MADEP Bureau of Waste Site Cleanup – Map showing sensitive environments and Attachment C, Map showing Natural Heritage Areas and Endangered Species Areas).

3. The College property has not been previously identified as being in a conservation area or a Flood Hazard Zone.

4. Groundwater flow direction at the College is near the north-south flow divide. Town GIS mapping shows the water table to be extremely flat in the area with the groundwater flow direction, north or south being indefinite. Water table mapping by Geraghty & Miller in 1992, indicates northward flow from the area of the College.

Site Characteristics

1. **Published Information**

a. Geologic Setting. The site is located on the Sandwich Moraine. Soils on the moraine are generally described as:

> Mostly sand and gravel. Abundant fine sand, silt and clay.
> Till and boulders generally occur above stratified drift.

b. Soil Type. The surficial soils in the undeveloped and undisturbed areas of the College property are classified as the Plymouth-Barnstable Complex. (USDA, SCS, 1993). The Plymouth Barnstable soils are characterized as being on rolling and undulating land. They are excessively and well drained soils on the side slopes of moraines. The subsoil grades from sandy loam to loose course sand. Boulders are common.

c. Site Topography. The majority of the College property, including the athletic field has been altered to accommodate the facility. Grading and filling is evident in the developed areas of the campus as the surrounding wooded area is comprised of irregular undulating topography. The land is comprised of rolling terrain with elevations ranging from approximately 95 to 130 feet above MSL.

d. Depth to Groundwater. The College property is in an area where groundwater has been mapped to be greater than 50 feet below the surface.

e. Hydraulic Conductivity. The College is in an area where earlier modeling efforts used a hydraulic conductivity of 50 - 200 feet per day.

2. Field Investigation Results

Investigations occurred at three sites: One (Site A) at the athletic field, one on the northerly end of the wooded area (Site B) and one at the southerly end of the wooded area (Site C). At each of the three areas, one test pit was completed and one deep soil boring and test well was installed. Percolation tests were completed at Areas A and B. The investigative efforts are described below.

a. Test Pit Observations. On September 8, 2003 three (3) test pits were excavated on the property. One test pit was excavated in each of the three investigation sites. Test pits were excavated to depths ranging from 8 to 12 feet. Test pit logs are included as Attachment D. Findings are summarized below.

- Site A – Athletic Field. Several large boulders were present in the interval from the surface to five feet below grade in test pit TP-3 at Site A. Medium to course sand was observed surrounding and below the boulders. At the test pit at Site A, fill material was observed to a depth of 30 inches. Groundwater was not observed.

- Site B – Woods North. At test pit TP-2 at Site B, fill material was observed to a depth of approximately 4 feet and boulders were encountered. No percolation test was performed in TP-2. The presence of boulders indicated the location was probably not suitable. Also, because native soils, the target for percolation tests were several feet below grade in the test pit, they could

not be safely accessed. Below the fill, the section was comprised of sandy loam. Boulders were encountered throughout the exposed section. Groundwater was not observed.

- Site C – Woods South. At test pit TP-1 at Site C, loamy sand was observed over the entire exposed section. Groundwater was not observed.

b. Percolation Tests. Percolation tests were conducted at test pits TP-1 at area B and TP-3 in Area A to obtain a generally qualitative assessment of the soil's capacity to allow water to infiltrate. Percolation test logs are included as Attachment E. Percolation rates are compared to standards in "Guidelines for the Design Construction, Operation and Maintenance of Small Sewage Treatment Facilities with Land Disposal".

- Site A – Athletic Field. Percolation rate at TP-3 in area A was 8.67 minutes per inch. At that percolation rate, (the range 5-10 minutes/inch) MADEP guidance recommends application rates of 4 gpd/sq ft for open beds and 1.5 gpd/sq ft for leaching trenches.

- Site C – Woods South. Percolation rate at TP-1 in area C was 0.67 minutes per inch. At that percolation rate, MADEP guidance recommends application rates of 5 gpd/sq ft for open beds and 2.5 gpd/sq ft for leaching trenches.

c. Deep Boring Observations. One deep soil boring was installed at each investigation site to characterize deep soil conditions and to determine the depth to groundwater. Each boring was completed as a test well. Each soil boring was advanced to a depth of approximately 84 to 94 feet based on the depth at which groundwater was encountered. The borings were advanced at least 15 additional feet when groundwater was encountered at a depth of approximately 65 to 70 feet in each boring. Soil boring logs are included as Attachment F.

- Site A – Athletic Field. Test Well TW-1 was drilled at investigation Site A at the athletic field to a depth of 94 feet. Due to several boulders in the shallow subsurface, the location of TW-1 had to be relocated two times. At the third site, boulders were still penetrated to a depth of 30 feet. After this depth, some boulders were present, but were not as prevalent as in the shallower material. The soils that were recovered were primarily medium to fine sands.

- Site B – Woods North. Test Well TW-3 was drilled at investigation Site C to a depth of 84 feet. TW-3 yielded similar conditions as TW-2 with well graded fine to medium sand comprising the majority of the samples.

- Site C – Woods South. Test Well TW-2 was drilled at investigation Site B to a depth of 94 feet. TW-2 had much more favorable conditions than TW-1. The bulk of the soil was well sorted medium to fine sand and no boulders were encountered.

d. Deep Hydraulic Conductivity. The mounding evaluation in this investigation is based on a hydraulic conductivity value of 100 feet per day. This value was obtained through in-situ hydraulic conductivity testing that was performed in the completed test wells. The hydraulic conductivity calculation is provided as Attachment G. This value is consistent with values between 50 and 200 feet per day that have been used in earlier groundwater models of the area.

e. Groundwater Flow Direction. Groundwater flow direction is relevant to this study to determine into which watershed the treated effluent will flow. Depth to water measurements and the calculated groundwater elevations may indicate a groundwater flow direction toward the southwest rather than toward the north as regionally mapped. The linear pattern of the well locations and the minor difference (< 0.4 feet in measured elevation) may limit the accuracy of the interpretation. However, it is also possible that on a very localized scale, flow could be toward Lake Wequaquet.

f. Infiltration Capacity. Based on the available area and the percolation test infiltration rates, potential treated wastewater infiltration rates have been estimated. The athletic field has been eliminated from further consideration because of the poor subsurface conditions. In the woods area, two proposed recharge facilities have been laid out as shown on Figure 3. One area is 600' x 280', representing 168,000 square feet or 3.8 acres. It has been estimated that 2.8 acres within that area would be used for recharge. The other area is 520' x 280', representing 145,600 square feet or 3.0 acres. It has been estimated that approximately 2.5 acres within that area could be available for recharge. Based on the percolation rate of less than 2 minutes per inch, infiltration rates of 5 gpd/sq. ft. for sand beds and 2.5 gpd/sq. ft. for infiltration trenches have been estimated for this site.

Sand Beds: If sand beds are constructed over an area of 4.5 acres, an infiltration capacity of 980,000 gpd is calculated (5 gpd/sq. ft. x 196,020 sq. ft.). For the purposes of additional discussion, this will be considered to be 1 MGD.

Trenches: Based on the dimensions of the two areas, it has been calculated that 17, 500 feet of trenches can be built. This is based on an eight-foot width for each trench (3 foot trench plus 3 foot reserve plus 2 foot space). The 280-foot width of the selected areas can hold 35 trenches each with a length of 520 or 600 feet respectively. If each foot of trench has 7 square feet of recharge area,(3 square feet on bottom and two square feet on each side wall) then the capacity of the 17,500 feet of trenches could be 665,000 gpd.

g. Potential Mounding. Because the depth to groundwater is approximately 70 feet below grade, groundwater mounding is not believed to be a limiting factor at this site. Using an analytical mounding calculator (the Hantaxis program, used by MADEP to calculate mounding impacts), a worst case-mounding scenario was completed. The mounding calculation was based on recharging one million gallons per day in an area 280' x 1,100 feet and a hydraulic conductivity value of 100 feet per day. The results of the preliminary mounding analysis are presented in Attachment H.

The preliminary mounding analyses indicate that if the site has a hydraulic conductivity around 100 feet per day, and 1 MGD are discharged over the proposed area, then a mound of approximately 12 feet can develop. A mound of this magnitude will not impact surface facilities such as proximal buildings or septic systems. Some radial flow would be induced, however, given the natural groundwater gradient in the area, water flowing radially away from the College property would ultimately be captured by the regional flow system.

CONCLUSIONS

The investigation described above has resulted in the following conclusions regarding use of Cape Cod Community College for the recharge of treated municipal wastewater:

1. The College is located in an area (Area "B") that was originally identified in the Town's remote site screening process. The College is located in an area remote from water supply wells and Zone IIs and other environmentally sensitive areas such as Areas of Critical Environmental Concern (ACECs), wetlands, or natural heritage sites.

2. The presence of fill material and the large number of boulders reduces the suitability of the athletic field area.

3. A percolation rate of less than 2 minutes per inch was obtained, suggesting suitable soils for recharge near the surface.

4. Groundwater is found at depths ranging from 65 to 70 feet. Groundwater mounding, resulting from recharge is not a concern at this site. Based on the application of 1 MGD at this site, distributed over 5 acres, a mound of 12 feet is projected.

5. The candidate site for wastewater recharge is comprised of approximately 5 acres. It is wooded and comprised of rolling hills indicating that there would be a significant amount of site work to clear and grade the site for the installation of recharge facilities.

6. If open sand beds are utilized a recharge capacity of approximately one million gallons per day is possible. If leaching trenches are used, the recharge capacity is reduced to approximately 660,000 gallons per day.

7. The site is located approximately 15,000 feet from the WPCF. The distance, in itself, is not an advantage or disadvantage, until compared to the distances of other candidate sites. Sewering the college is a component of a planned project. Piping for treated wastewater could be integrated into that project to lower costs.

To summarize, the College has the potential to be a suitable site to discharge treated effluent. The College will be included in the comparative analysis to be completed as part of the facilities plan.

Please call with any questions or comments.

Very truly yours,

D. Determination of High Groundwater Elevation

1. Method used:

☐	Depth observed standing water in observation hole	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☐	Depth weeping from side of observation hole	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☐	Depth to soil redoximorphic features (mottles)	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☒	Groundwater adjustment (USGS methodology)	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches

2. Index Well Number _____ Reading Date _____ Index Well Level _____

Adjustment Factor _____ Adjusted Groundwater Level _____

E. Depth of Pervious Material

1. Depth of Naturally Occurring Pervious Material

   a. Does at least four feet of naturally occurring pervious material exist in all areas observed throughout the area proposed for the soil absorption system? Yes ☒ No ☐

   b. If yes, at what depth was it observed? Upper boundary: 32" inches _____ Lower boundary: 105" inches _____

F. Certification

I certify that I have passed the soil evaluator examination* approved by the Department of Environmental Protection and that the above analysis was performed by me consistent with the required training, expertise and experience described in 310 CMR 15.017.

_____ Signature of Soil Evaluator

_____ Date

J. Jefferson Gregg Typed or Printed Name of Soil Evaluator

_____ *Date of Soil Evaluator Exam

_____ Name of Board of Health Witness

_____ Board of Health

Note: This form must be submitted to the approving authority with Percolation Test Form 12

Percolation Test Results

FORM 12 - PERCOLATION TEST

Location Address or Lot No. Cape Cod Community College

COMMONWEALTH OF MASSACHUSETTS

Barnstable, Massachusetts

Percolation Test*		
Date: 9/15/03	Time:9:15 AM	
Observation Hole#	TP-1	TP-3
Depth of Perc	42 inches	60 inches
Start Pre-soak	9:47 am	2:22 pm
End Pre-soak	10:02 am	2:37 pm
Time at 12"	10:02 am	2:39 pm
Time at 9"	10:05 am	2:59 pm
Time at 6"	10:07 am	3:25 pm
Time (9"-6")	2 min	26 min
Rate Min./Inch	0.67 min/inch	8.67 min/inch

*Minimum of 1 percolation test must be performed in both the primary area AND reserve area

Site Passed ☐ Site Failed ☐

Performed by: J. Jefferson Gregg

Witnessed by: _____

Comments: Unofficial Perc Tests, - not witnessed by State - TP-1 located adjacent to Parking Lot, TP-3 located on far side of athletic fields.

Re: Effluent Mitigation Investigation Project
Task 7 – Lorusso Property Investigation
S&W No. 20190.0

Dear Mr. Giordano:

In accordance with your request and the Contract for Consultant Services for the Effluent Mitigation Investigation Project Task 7 – Lorusso Property Characterization, we have completed a preliminary evaluation of the Lorusso property along the power lines, just south of Route 6, for the recharge of treated effluent. In accordance with paragraph 2.2.5.2 of the Contract for Consultant Services, QA/QC procedures of the Scope of Work were adhered to in the completion of this project. In accordance with paragraph 2.2.5.4 of the Contract, Stearns & Wheler is providing five (5) bound copies, one (1) unbound copy, and one computer copy of this letter report. The evaluation was completed consistent with the Barnstable Wastewater Facilities Plan (WWFP) recommendation to identify and utilize remote sites for the purpose of discharging treated wastewater to the subsurface.

BACKGROUND INFORMATION

The Town of Barnstable is in the process of completing a Wastewater Facilities Plan (WWFP) that evaluates future options for the Town to collect, treat and dispose of municipal wastewater. A component of the WWFP recommended the identification of parcels of land, remote from the existing Water Pollution Control Facility (WPCF), where treated wastewater can be reclaimed by discharging it back to the subsurface in order to replenish groundwater resources in the Town. Utilization of remote sites was recommended because the WWFP and related work concluded that the recharge capacity of the existing plant effluent discharge beds might be limited due to potential adverse impacts related to groundwater mounding. In the course of completing the WWFP, the Town undertook a remote site screening process to identify areas of the Town where suitable parcels may exist. Following the completion of that screening process, the Town

began to identify specific parcels that could be further evaluated for suitability. One of those parcels being investigated is the Lorusso property. Reference is made to Figure 1 for the location of the Lorusso property.

The subject property is located along the power line right-of-way, east of Phinney's Lane, just south of Route 6 and north of the Cape Cod Aggregate operation. The property consists of approximately 11 acres and is comprised of lightly vegetated, undulating terrain. Access for future development is somewhat limited by three sets of power lines that cross the site from east to west. The power line poles did not significantly limit investigation efforts other than having a 30-foot radius buffer around them. The presence of the power line poles could limit the areal extent of recharge facilities but sufficient areas of land for construction of recharge facilities appear to be present between the poles.

SCOPE OF WORK

The Scope of Work for the investigation included the following tasks:

Subtask 7.1 Site Visit. Prior to initiating site work on the site, an initial reconnaissance trip to the site was conducted. Additionally, discussions were held with site owners. The purpose of these discussions was to determine what restrictions the owner might impose that could impact investigative efforts or future use of the site.

Subtask 7.2 Initial Screening. Following the site visit, an initial screening was completed that evaluated the suitability of the site in terms of siting criteria considered in earlier phases of the site identification and screening process, including but not limited to location with respect to:

1. In Wellhead Protection Zones I, II and III
2. In Areas of Critical Environmental Concern
3. Near vernal pools
4. Near wetland
5. In areas of rare and endangered plant and wildlife habitat
6. In conservation areas
7. In flood hazard zones
8. Releases of oil or hazardous materials
9. Drainage basin

Under this subtask, Stearns & Wheler did not repeat the Town's earlier screening efforts but refined and updated the previous work.

Subtask 7.3 Test Pits. Five backhoe test pits were completed at representative locations across the property. Test pits were excavated to a depth of 7 to10 feet. A soil evaluator logged soil stratigraphy in the test pits. Percolation tests were completed at four of the five test pits. A percolation test was not completed at the second site because low permeability soils were present and the depth to natural soils precluded safely entering the test pit to conduct the test. Test pit locations are shown on Figure 2.

Subtask 7.4 Soil Borings. Three soil borings were drilled. Borings were distributed across the site to generally characterize the subsurface. The proposed work plan specified the borings would be advanced to a depth at least 10 feet below the existing water table. Based on the depth at which the water table was encountered, the borings were advanced to depths of 76, 76, and 86 feet, respectively. Split spoon samples were collected at 5 foot intervals from each boring. Stearns & Wheler recorded soil types on a boring log. Boring locations are shown on Figure 2.

Subtask 7.5 Observation Wells/Slug Tests. Upon completion of the first soil boring, a field determination was made that the site is a likely candidate for disposal, so the soil borings were completed as observation wells. In-situ hydraulic conductivity testing (slug testing) was completed in all of the wells to determine the permeability of the deeper soils. This data was obtained to support regional mapping data and in order to complete a groundwater mounding analysis, a requirement of a groundwater discharge permit application, should the Town decide it wants to pursue a permit for this parcel.

Subtask 7.6 Report of Findings. A written report for the Town that presents the field investigation results and provides recommendations regarding the use of the subject parcel for treated effluent disposal is included herein.

Subtask 7.7 Meetings. Time was allocated for meetings related to this site investigation. One meeting where preliminary results were presented was held on October 7, 2003. An additional meeting is anticipated.

EVALUATION RESULTS

The results of the Lorusso Property investigation are presented in this section. The results are organized in the following order:

- Location Considerations.
  - Summary of initial site screening considerations and results

- Site Characteristics

  - Published Information from literature about the general characteristics of the site.

  - Field Investigation Results – detailed results from the Stearns & Wheler field investigation.

A. Location Considerations

Location considerations relate to the suitability of the site based on its setting. These criteria were evaluated by the Town in their initial screening process and included those factors listed in the introduction section of this letter. Stearns & Wheler reviewed and updated these siting criteria.

The results of that screening process indicated that:

1. There are four public supply wells within one mile of the property. The property is located within the Zone II of one of those wells, the Barnstable Fire District (BFD) Well No. 1. The well is located approximately 2,000 feet from the property, near Phinney's Lane, north of Route 6 (See Attachment A – MADEP Water Supply Protection Areas Map). The BFD Well No. 1 is presently active and produces approximately 300 gallons per minute from the interval between 44 and 59 feet below grade.

2. The property is not in an Area of Critical Environmental Concern or in any other designated environmentally sensitive area. (See Attachment B Map – MADEP Bureau of Waste Site Cleanup – Map showing sensitive environments and Attachment C, Map showing Natural Heritage Areas and Endangered Species Areas).

3. The property has not been previously identified as being in a conservation area or a Flood Hazard Zone.

4. Town GIS mapping shows the groundwater flow direction at the property to be toward the northeast.

B. Site Characteristics

1. Published Information

a. Geologic Setting. The site is located on the Sandwich Moraine. Soils on the moraine are generally described as:

Mostly sand and gravel. Abundant fine sand, silt and clay.
Till and boulders generally occur above the stratified drift.

b. Soil Type. The surficial soils in the undeveloped and undisturbed areas of the Lorusso property are classified as the Plymouth-Barnstable Complex and as the Eastchop loamy sand. (USDA, SCS, 1993). The soils are similar and are characterized as being on rolling and undulating land. They are excessively and well-drained soils on the side slopes of moraines. The subsoil grades from sandy loam to loose course sand. Boulders are common in the Plymouth-Barnstable Complex according to the SCS description, but none were detected in the field investigation.

c. Site Topography. The property is comprised of rolling terrain with elevations ranging from approximately 80 to 120 feet above MSL.

d. Depth to Groundwater. The property is in an area where groundwater has been mapped to be greater than 5 feet below the surface. The site investigation revealed that the water table is at a depth of approximately 65 feet.

e. Hydraulic Conductivity. The property is in an area where earlier modeling efforts used a hydraulic conductivity of 50 to 200 feet per day.

2. Field Investigation Results

As described above, the investigation entailed the installation of five test pits, the completion of four percolation tests and the installation of three soil borings, which were completed as observation wells. The borings and test pits were distributed across the site to provide a general characterization of the entire property. The field work and observations are described below.

a. Test Pit Observations. On September 8, 2003 five test pits were excavated on the property. Test pit logs are provided in Attachment D. Two of the test pits (TP-1 and TP-2) were located at the eastern end of the property. Both of these test pits apparently penetrated fill material. Although there was no prior reason to believe that the property had been reworked in any way, the two eastern test pits revealed a buried topsoil horizon at a depth of about 6 feet. Above and below the buried soil horizon the subsurface was comprised of medium sand. At a depth of approximately 6 feet in test pit TP- 2, a low permeability, silt to clay layer was penetrated. The presence of the fill material does not necessarily prevent the use of the area for recharge facilities, although MADEP does specify certain construction requirements for facilities located in fill material. In those instances, the existing fill must be removed and the facilities located on the natural material or new fill with certain properties must be brought in to replace the removed fill. This would represent significant additional costs for grading and filling. A greater

restriction is the presence of the low permeability layer in test pit TP-2. In that particular location, the subsurface soils may not be ideal for the construction of a recharge facility.

The three test pits in the more westerly extremes of the property possessed more typical soil properties. No fill was present and the underlying soils were uniform, clean, medium to fine sands.

b. Percolation Tests. Percolation tests were conducted at test pits TP-1, 3, 4 and 5 to obtain a generally qualitative assessment of the soil's capacity to allow water to infiltrate. No percolation test was performed in TP-2 because of the presence of the low permeability layer at a depth of approximately six feet. Percolation test logs are included as Attachment E. Percolation rates are compared to standards in "Guidelines for the Design Construction, Operation and Maintenance of Small Sewage Treatment Facilities with Land Disposal".

The percolation rate at TP-1 was 4.6 minutes per inch which is acceptable for recharge facilities. The percolation rate at the remaining three test pits was under 2 minutes per inch, indicating rapidly draining soils and preferable conditions for recharge facilities.

c. Deep Boring Observations. Three deep soil borings were installed and completed as observation wells. The borings all penetrated similar sediments. Medium to fine sand was penetrated to a depth of 40 feet in TW-1 and TW-2. The silty to silty clay layer seen in TP-2 was not observed in TW-2 suggesting that it may not have been a continuous layer. In TW-1 and TW-2 the subsurface soils become much finer, grading to silt below 40 feet. The finer sand to silt was encountered at a depth of 70 feet in TW-3. The fine sand to silt will reduce the site's capacity to accept and disperse water but given the depth of groundwater, approximately 65 feet, mounding is not anticipated to be a concern.

d. Deep Hydraulic Conductivity. Mapped hydraulic conductivity values were confirmed through the completion of in-situ hydraulic conductivity testing. A value of approximately 50 feet per day was obtained (See Attachment G). This value is consistent with values between 50 and 200 feet per day that have been used in earlier groundwater models of the area. In earlier mapping (Geraghty & Miller 1993) a value of 50 feet per day was assigned to this area. In more recent mapping, USGS has used higher values but specific information was not available from USGS. The value of 50 feet per day has been used for mounding calculations to be conservative.

e. Groundwater Flow Direction. Groundwater flow direction is relevant to this study to determine into which watershed the treated effluent will flow. Depth to water measurements and the calculated groundwater elevations may indicate a groundwater flow direction toward the south, opposite current Town-wide mapping. The fact that the site is on the moraine, near the north-south flow divide explains why the flow direction is not definitively determined. At that location, flow could conceivably be in either

direction. It cannot be definitively stated at this time what the flow direction at the site is. If the site is in fact located on or near the flow divide, mounding will result in some radial flow, but eventually water will resume the regional flow direction.

f. Infiltration Capacity. Based on the available area and the percolation test infiltration rates, potential treated wastewater infiltration rates have been estimated. The available area is limited due to the presence of a number of utility poles on the property. The utility poles require recharge areas to be separated and laid out in between the lines of poles. For the purposes of developing a preliminary estimate of the recharge capacity of the property, potential leaching trench or sand bed areas were laid out on the property. Conceptual layouts are shown on Figure 3. The total area of the three recharge areas is approximately 5.0 acres. Allowing some of that area to be set aside for berms, buffers or related facilities, it is estimated that 4 acres within those areas would be available for recharge. Based on the percolation rate of less than 2 minutes per inch, infiltration rates of 5 gpd/sq. ft. for sand beds and 2.5 gpd/sq. ft. for infiltration trenches have been estimated for this site.

Sand Beds: If sand beds are constructed over an area of 4 acres, an infiltration capacity of 870,000 gpd is calculated (5 gpd/sq. ft. x 174,240 sq. ft.). For the purposes of additional discussion, this will be considered to be 0.9 MGD.

Trenches: Based on the dimensions of the three recharge areas, it has been calculated that 26,500 linear feet of trenches can be built. This is based on an eight foot width for each trench (3 foot trench plus 3 foot reserve plus 2 foot space). The selected areas can hold 32, 32 and 15 trenches respectively with lengths of 260, 400 or 360 feet respectively. If each foot of trench has 7 square feet of recharge area,(3 square feet on bottom and two square feet on each side wall) then the capacity of the 26,500 feet of trenches could be 460,000 gpd.

g. Potential Mounding. Because the depth to groundwater is approximately 65 feet below grade, groundwater mounding is not believed to be a limiting factor at this site. Using an analytical mounding calculator (the Hantaxis program, used by MADEP to calculate mounding impacts), a worst case mounding scenario was completed. The mounding calculation was based on recharging 900,000 gallons per day in an area 960 feet by 320 feet and a hydraulic conductivity value of 50 feet per day. The results of the preliminary mounding analysis are presented in Attachment H.

The preliminary mounding analyses indicate that if the site has a hydraulic conductivity around 50 feet per day, and 900,000 gpd are discharged over the proposed area, then a mound of approximately 12 feet can develop. A mound of this magnitude will not impact surface facilities such as proximal buildings or septic systems. Some radial flow would be induced, however, given the natural groundwater gradient in the area, water flowing

radially away from the property would ultimately be captured by the regional flow system.

CONCLUSIONS

The investigation described above has resulted in the following conclusions regarding use of the Lorusso for the recharge of treated municipal wastewater.

1. The Lorusso property consists of approximately 11 acres of undeveloped acreage that serves as a power line right-of-way and the owner has expressed willingness to have the Town use this acreage for wastewater recharge.

2. The property has a number of utility poles on it, which limits the area in which recharge facilities can be constructed. The property has very irregular terrain. Use of the site would take a significant amount of cutting and filling to create level areas suitable for leach field or trenches. The Town may want to consider the use of wick wells for discharge at this site. A discussion of the present status of wick well utilization is provided under separate cover.

3. The presence of fill material, albeit material that is generally indistinguishable from the native sand at the property, could impact the construction of recharge facilities based on MADEP requirements related to building recharge facilities in fill material.

4. A percolation rate of less than 2 minutes per inch was obtained over much of the area, suggesting suitable soils for recharge near the surface. A one acre site at the east end of the property is included in the conceptual layout, however, a percolation rate of closer to 5 minutes per inch was obtained in the test pit at the east end of the site. Soils with lower permeability at the east end of the site might preclude or limit the performance of recharge facilities.

5. Soils that comprise the aquifer at the site, at depths of 40 to 80 feet are very fine sands and silts. These soils are finer grained and less permeable than those seen at other sites. Slug testing indicated that the deeper hydraulic conductivity could be as low as 50 feet per day. Despite the low hydraulic conductivity, mounding is not considered to be an issue and the deeper subsurface soils should have the capacity to receive the recharged water.

6. Groundwater is found at depths ranging from 65 to 70 feet. Groundwater mounding, resulting from recharge is not a concern at this site. Based on the application of 0.9 MGD at this site, distributed over the total recharge area, a mound of 12 feet is projected.

7. The property is located in the Zone II of a proximal supply well that is located about 2,000 feet away. If a flow rate of approximately one foot per day is estimated, the property is located about 5 years travel time from the well. MADEP has established additional requirements if the travel time is less than two years.

8. The available area for wastewater recharge is comprised of approximately 4 acres. If open sand beds are utilized, a recharge capacity of approximately 900,000 gallons per day is possible. If leaching trenches are used, the recharge capacity is reduced to approximately 460,000 gallons per day.

9. The site is located approximately 15,000 feet from the WPCF. The distance, in itself, is not an advantage or disadvantage, until compared to the distances of other candidate sites.

To summarize, the Lorusso property has the potential to be a suitable site to discharge treated effluent. The Lorusso property will be included in the comparative analysis to be completed as part of the facilities plan.

Form 11 - Soil Suitability Assessment for On-Site Sewage Disposal

D. Determination of High Groundwater Elevation

1. Method used:

☐	Depth observed standing water in observation hole	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☐	Depth weeping from side of observation hole	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☐	Depth to soil redoximorphic features (mottles)	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches
☒	Groundwater adjustment (USGS methodology)	A. _____ inches	B. _____ inches	C. _____ inches	D. _____ inches	E. _____ inches

2. Index Well Number _____ Reading Date _____ Index Well Level _____

Adjustment Factor _____ Adjusted Groundwater Level _____

E. Depth of Pervious Material

1. Depth of Naturally Occurring Pervious Material

   a. Does at least four feet of naturally occurring pervious material exist in all areas observed throughout the area proposed for the soil absorption system? Yes ☒ No ☐ (EXCEPT TP-2)

   b. If yes, at what depth was it observed? Upper boundary: 24" inches _____ Lower boundary: 120" inches _____

F. Certification

I certify that I have passed the soil evaluator examination* approved by the Department of Environmental Protection and that the above analysis was performed by me consistent with the required training, expertise and experience described in 310 CMR 15.017.

_____ Signature of Soil Evaluator

_____ Date

_____ Typed or Printed Name of Soil Evaluator

_____ *Date of Soil Evaluator Exam

_____ Name of Board of Health Witness

_____ Board of Health

Note: This form must be submitted to the approving authority with Percolation Test Form 12

Form 11 - Soil Suitability Assessment for On-Site Sewage Disposal

Task 8 Report – Candidate Site Evaluation and Comparison **Draft Report**
S&W No. 20190.0

Dear Mr. Giordano:

In accordance with the Town's Notice to Proceed dated October 28, 2003, and the Contract for Consultant Services for the Effluent Mitigation Investigation Project, dated July 23, 2003, we have completed this Task 8 Draft Report for the Candidate Site Evaluation and Comparison.

This report is prepared in accordance with paragraph 2.2.5.2 of the Contract, and QA/QC procedures of the Scope of Work were adhered to in the completion of this task. The evaluation was completed consistent with the Barnstable Wastewater Facilities Plan (WWFP) recommendation to identify and utilize remote sites for the purpose of recharging treated wastewater to the subsurface.

BACKGROUND INFORMATION

The Town of Barnstable (Town) is in the process of completing a WWFP that evaluates future options for the Town to collect, treat, and discharge municipal wastewater. A component of the WWFP called for the identification of parcels of land, remote from the existing water pollution control facility (WPCF) where treated advanced secondary wastewater can be reclaimed by discharging it back to the groundwater system. Utilization of remote sites for the recharge of treated wastewater was recommended because the WWFP and related work concluded the recharge capacity of the current effluent disposal beds at the existing plant may be limited due to potential adverse impacts resulting from groundwater mounding. In the course of completing the WWFP, the Town undertook a remote site screening process to identify areas of the Town where suitable parcels may exist. Following the completion of that screening process, the Town identified several specific sites and parcels for preliminary site evaluation for effluent discharge. Preliminary evaluations have been completed for the following four sites:

1. McManus property and adjacent parcels (Site B).
2. Barnstable Municipal Airport (Site C).
3. Cape Cod Community College (Site D).
4. Lorusso parcels at the powerline easement (Site E).

These sites are illustrated on Figure 1, along with Site A, which is the Hyannis WPCF. The preliminary evaluations for these sites were documented in previous task reports.

The purpose of this Task 8 Report is to summarize each site's effluent discharge characteristics and provide a comparison evaluation of the sites with various alternative discharge technologies.

SCOPE OF WORK

The Scope of Work for the investigation is summarized below:

Subtask 8.1 - Compilation of Data

Prepare a description of the alternatives analysis methodology employed in the technical evaluations of the remote effluent disposal sites. Compile the data from the completed preliminary site evaluations and identify advantages and disadvantages of each site. Compile data on each site to facilitate comparison including, but not limited to:

- Distance from Hyannis WPCF
- Available area for effluent discharge facilities.
- Site access considerations.
- Abutting land use.
- Distance to sensitive receptors, such as freshwater ponds, wetlands, residential neighborhoods, water supply contribution areas, historic districts, etc.

Subtask 8.2 - Technology Evaluation

Prepare a technology evaluation to develop effluent discharge technology data for each site. Perform a preliminary screening analysis to identify potential effluent discharge technologies. Develop and include conceptual design information (facility sizing, force main sizing and length, operations considerations, flow capacity, etc.). Develop capital and operation and maintenance (O&M) costs for each technology at each site. Incorporate data compiled in Subtask 8.1.

Subtask 8.3 - Comparative Evaluation

Upon completion of the technology evaluation, compare the sites and technologies to each other with respect to suitability for remote effluent disposal. Prepare a matrix to facilitate the comparison including, but not limited to, the following criteria:

- Distance from WPCF as a factor in determining effluent transmission construction costs.

- Site topography as an impact to constructability.

- Soil permeability to identify the site's ability to accept water.
- Depth to groundwater to identify where mounding will have the least impact.
- Abutting land use for compatibility of the proposed operation with surrounding land use.
- Aesthetic impacts related to potential odors, view, or noise.
- Proximity to sensitive receptors such as wetlands, surface water, or water supply wells.
- Capital costs, including property purchase, potential easements, construction, and fiscal/legal/engineering costs.
- O&M costs to operate the alternative facilities at the various sites.

Summarize the sites in a matrix according to the criteria listed above in addition to other relevant criteria identified during the course of the evaluation. Provide conceptual designs for the most favored technologies at each site and include proposed layouts of the facilities.

Subtask 8.4 - Draft Report Preparation

Prepare and submit a draft report summarizing the preceding subtasks.

Subtask 8.5 - Final Report Preparation

Prepare and submit a final report based on Town's comments.

EVALUATION RESULTS

The results of the Candidate Site Evaluation and Comparison are presented in this section. The results are organized in the following order:

1. Site description and data summary.
2. Effluent discharge technology identification and descriptions.
3. Screening of effluent discharge technologies.
4. Evaluation of feasible technologies at specific sites.
5. Wastewater treatment issues and requirements for effluent discharge at new remote sites.
6. Development and comparison of conceptual effluent discharge designs.
7. Summary and recommendations.

Site Description and Data Summary

As previously stated, the sites to be evaluated are designated as follows:

1. McManus property and adjacent parcels (Site B).
2. Barnstable Municipal Airport (Site C).
3. Cape Cod Community College (Site D).
4. Lorusso parcels at the powerline easement (Site E).

The sites are shown graphically on the attached figures:

Figure 1 - Potential Discharge Sites and Project Location Map
Figure 2 - Potential Discharge Sites and Land Use
Figure 3 - Potential Discharge Sites and Groundwater Considerations
Figure 4 - Potential Discharge Sites and Protected Habitats

1. The McManus property and adjacent parcels (Site B) are located just south of the intersection of Route 132 and Route 6. The site consists of four parcels owned by the Town, the State, and a private entity. The parcels are located approximately 1,100 feet south of the intersection on the northeast side of Route 132 and approximately 12,600 feet from the WPCF. The site is trapezoidal in shape and occupies approximately 23 acres.

2. The Barnstable Municipal Airport property is located at the intersection of Route 132 and Route 28, north of the "Airport Rotary." The property consists of one parcel owned by the Town which is located approximately 8,600 feet from the WPCF. Three portions of the airport property were chosen as the focus of our evaluation illustrated as Sites C on the attached figures. The sites are located to the east of the intersection of the two runways in the southern section of the facility. This area was chosen as the most appropriate effluent discharge locations on the property for the following reasons:

    a. It has the space for multiple recharge areas in close proximity to each other and will be easier to construct, operate, and maintain.

    b. Future airport construction in this area is unlikely.

    c. Groundwater elevations are lowest at this location.

    d. This portion of the property is a greater distance from protected priority habitats.

3. The Cape Cod Community College site (Site D) is located northeast of the intersection of Routes 6 and 132 (Exit 6 of the Mid-Cape Highway). The site consists of two parcels owned by the State, located approximately 1,200 feet north of the intersection of Route 132 and approximately 15,500 feet from the WPCF. The eastern portion of the site was chosen as the focus of our evaluation because it is the largest contiguous area; it is fairly remote; and it had the best

soils based on the test pits and soil borings performed during the preliminary evaluation. The focus area occupies approximately 27 acres.

4. The Lorusso site (Site E) is located along the power line right-of-way, east of Phinney's Lane, just south of Route 6 and north of the Cape Cod Aggregate operation. The site consists of five properties totaling approximately 11 acres and is privately owned. It is located approximately 10,400 feet from the WPCF.

Table 1 presents data collected for each site relating to the site locations, land uses, environmental sensitivity, topography, and soils.

Effluent Discharges Technology Identification and Descriptions

All wastewater treatment facilities require a means of discharging and/or reusing treated effluent. The technology selected for effluent disposal needs to be specific to the discharge site to minimize the impacts of treated effluent on nearby surface and groundwaters, while utilizing each site's unique features. This section describes available technologies and provides advantages and disadvantages for each in order to screen the technologies. A comparison of the effluent discharge technologies is summarized on Table 2.

1. **Sand Infiltration Beds.** Sand infiltration beds are open basins designed to allow treated effluent to flow across the bottom of the basin and percolate through the sand bed, through the unsaturated zone, and then to the groundwater. Bed maintenance is relatively easy because the bed is exposed at the surface and the sand surface can be raked or replaced if the sand becomes plugged with effluent solids. Hydraulic loading rates of 5 gallons per day per square foot (gpd/sf) of bed area are typical for the soils at the sites evaluated based on the preliminary evaluations.

   Effluent disposal in sand infiltration beds has the following advantages:

   - Bed construction is relatively simple.
   - Operation and maintenance (O&M) is relatively easy and O&M costs are lowest.
   - Hydraulic loading rates are typically higher than other disposal methods, which allows them to take up less area.

   Effluent disposal in sand infiltration beds has the following disadvantages:

   - Construction of new beds requires the clearing of large areas of land, which may have a visual impact.
   - Infiltration beds do not have secondary uses, such as parking lots and recreational areas (as subsurface leaching or spray irrigation facilities might have).

- Extensive site work may be required for construction of new beds at new sites.

- Disinfection is typically required.

2. **Subsurface Infiltration.** Large–scale subsurface infiltration facilities typically utilize pump and piping systems to pressure dose infiltration areas (trenches, beds, or galleries) where the effluent percolates to the groundwater. Maintenance and cleaning of these systems is more difficult because the infiltration area is not exposed to the surface and effluent solids cannot be easily removed. Subsurface infiltration beds can have secondary uses, such as parking lots, lawns, playing fields, and recreational areas. Hydraulic loading rates of 2.5 gpd/sf (to the trench or gallery base and side walls) are typical for the soils at the sites evaluated based on the preliminary evaluations.

   Subsurface infiltration facilities have the following advantages:

   - Disinfection is typically not required prior to discharge unless it is in a water supply recharge area.

   - Facilities are contained underground and can have a secondary use, such as parking lots and recreational areas.

   They have the following disadvantages:

   - Large land areas are required (larger than sand infiltration beds) due to lower hydraulic application rates.

   - Pressure dosing is typically required for large systems, which adds capital and O&M costs.

   - Extensive site work may be required for construction, particularly if the site is forested.

3. **Spray Irrigation**. Spray irrigation facilities are typically comprised of effluent pumps, distribution piping, and a spraying system consisting of risers and spray nozzles. Treated effluent is pumped through various distribution lines and discharged via spray nozzles to the surrounding area. Spray irrigation systems have often been used at golf courses and in large remote fields. Application rates for non-golf course areas are typically 2 inches per acre per week. Application rates for golf courses are typically based on the turf management needs.

   Effluent disposal using spray irrigation has the following advantages.

   - Allows for secondary use of land (i.e., golf courses).

   - Provides inexpensive means of irrigation, reducing clean water demands.

- Provides nitrogen uptake by plant life and also reduced nitrogen application at golf courses.

Effluent disposal using spray irrigation has the following disadvantages:

- Difficult to find locations suitable or willing to use spray irrigation.
- Limited cold weather use due to potential freezing problems.
- Disinfection is typically required.
- Spray nozzles may be subject to clogging.
- Requires secondary means of effluent disposal during winter months.
- Must meet more stringent MADEP requirements for reclaimed water use.
- Large areas are needed.

4. **Well Injection.** Well injection involves the discharge of treated effluent to groundwater below the land surface. The discharge is accomplished by pumping the effluent through wells that extend into permeable, saturated, and unsaturated geologic strata. When discharged into saturated strata, this type of discharge can be compared to the reverse of extracting water from a well.

   Wells can be designed to discharge a range of wastewater flows depending on site conditions, such as depth to groundwater and geological conditions. A potential concern of well injection is the mounding of groundwater in low elevation areas. As a result, well injection requires extensive testing prior to design and construction. This would include hydraulic conductivity tests, hydrogeologic surveys, and pilot testing.

   Well injection for effluent disposal has been implemented on a limited basis throughout the United States, and there are limited regulatory standards on the siting, design, construction, and operation of the wells. The recently completed pilot test for this technology at the Hyannis WPCF indicated that injection wells can become plugged with biological growth if the effluent is not chlorinated. Discussions with the Massachusetts Department of Environmental Protection indicate minimal support for the development of this technology because it requires chlorination that may create secondary impacts to the groundwater, such as the formation of disinfection byproducts, which may provide health risks.

   Effluent disposal with well injection has the following advantages:

   - The land area required would be much less than the area required for infiltration beds, subsurface infiltration, and spray irrigation. The effluent discharge would occur below the surface, and the surface would have minimal disruption.

   - Discharge points (wells) could be spread over a large area to minimize groundwater mounding.

   It has the following disadvantages:

- Effluent filtration is needed to provide a high level of nutrient and solids removal to minimize plugging in the wells.
- Relatively unproven technology in Massachusetts, with only recent testing at the Hyannis WPCF.
- Limited performance data is available.
- Chlorination is needed, which conflicts with guidance from the Massachusetts Department of Environmental Protection (MADEP).

Screening of Effluent Discharge Technologies

The screening of effluent discharge technologies is based on the description of each technology, the respective advantages and disadvantages, and the screening criteria discussed earlier in this report. A summary of effluent discharge technologies and a side-by-side comparison of screening criteria are included in Table 2. The following provides a brief discussion of the screening analysis.

Sand infiltration beds are a simple and reliable effluent discharge technology with relatively low operating costs.

Subsurface infiltration facilities are simple and reliable. These facilities are constructed below ground and therefore have minimal visual impacts, reduced potential for odors, and can provide secondary use of the land. Effluent discharge in subsurface infiltration facilities has higher land area requirements. Subsurface infiltration facilities are not easily cleaned. Therefore, the life of the facilities will be dependent on the quality of the effluent.

Spray irrigation is a simple and reliable effluent discharge technology with relatively low construction costs. It can provide additional nitrogen uptake and removal.

Effluent discharge through well injection has relatively low land requirements and relatively low construction costs. Well injection has the potential of plugging at the injection point due to build-up of fine solids and biofouling, and would require chlorination. This method does provide a means of effluent disposal at multiple potential sites with minimal land requirements; however, MADEP's resistance to support and permit this technology eliminates it from further consideration.

Therefore, only sand infiltration beds, subsurface infiltration, and spray irrigation technologies are recommended for further evaluation. These will be referred to as Technologies 1 through 3, respectively.

Evaluation of Feasible Technologies at Specific Sites

Each site (Sites B through E) was reviewed for the three technologies (Technology 1 through 3), and the results are as follows:

McManus Site (Site B): At this site, sand beds and subsurface infiltration were identified as appropriate technologies. Spray irrigation was identified as not appropriate due to the visual and misting impacts adjacent to Route 6.

Municipal Airport Site (Site C): At this site, subsurface infiltration was identified as an appropriate technology. Sand beds and spray irrigation were identified as inappropriate because they could produce areas of standing water which could attract birds and be a hazard to air traffic. Also, the sand bed technology would utilize above ground structures (berms) which are not allowed in close proximity to the runway.

Cape Cod Community College Site (Site D): At this site, sand beds and subsurface infiltration were identified as appropriate technologies. Spray irrigation was identified as not appropriate due to the visual and misting impacts adjacent to Route 6, the college center, and the interchange.

Lorusso Site (Site E): At this site, sand beds and spray irrigation were identified as appropriate technologies. Subsurface infiltration was identified as not appropriate because its lower hydraulic application rate in combination with the small site would result in a small discharge capacity.

Based on this evaluation, the following seven scenarios were developed for further evaluation:

B1: McManus site with sand beds
B2: McManus site with subsurface infiltration
C2: Municipal Airport site with subsurface infiltration
D1: Cape Cod Community College site with sand beds
D2: Cape Cod Community College site with subsurface infiltration
E1: Lorusso site with sand beds
E3: Lorusso site with spray irrigation

Wastewater Treatment Issues and Requirements for Effluent Discharge at New Remote Sites

As the Town considers developing new effluent discharge sites, potential future discharge limits must be considered. The following treatment issues and requirements are discussed with respect to the current Hyannis WPCF effluent quality:

1. Effluent that is discharged into subsurface leaching facilities must have low suspended solids to avoid plugging the soil infiltration system and requiring costly repairs. Effluent filtration would reduce this potential.

2. Effluent discharges upgradient of freshwater ponds and lakes would need phosphorus removal to avoid the creation of a phosphorus plume that could

migrate to the freshwater body and cause eutrophication. The Otis Air Force Base wastewater treatment facility discharge, and the eutrophication of Ashumet Pond in Falmouth and Mashpee is a recent Cape Cod example of this issue. This case study is described in the 2003 report by the U.S. Geological Survey entitled *"Reactive-Transport Simulation of Phosphorus in the Sewage Plume at the Massachusetts Military Reservation, Cape Cod, Massachusetts."* Groundwater modeling proposed for subsequent phases of the effluent mitigation evaluations will need to consider whether effluent discharge at the proposed sites would recharge into freshwater bodies and would require phosphorus removal.

3. Effluent discharge into Zone II areas will need to meet the MADEP *"Interim Guidelines on Reclaimed Water."* Effluent limits for this type of discharge would need to meet the following treatment and design standards:

   - pH: 6 to 9
   - BOD concentration: $\leq$30 mg/L
   - Turbidity: $\leq$5 Nephelometric turbidity units (NTU)
   - Fecal coliform content: $\leq$200 colonies/100 ml
   - TSS concentration: $\leq$10 mg/L
   - TN concentration: <10 mg/L

   These standards could be met by the addition of filtration facilities at the Hyannis WPCF and effluent chlorination.

   Effluent discharges in a Zone II area with less than a two-year travel time to a public water supply would need to meet the following more stringent treatment and design standards:

   - pH: 6 to 9
   - BOD concentration: $\leq$10 mg/L
   - Turbidity: $\leq$2 NTU
   - Fecal coliform content: median of no detectable colonies/100 ml and no single sample to exceed 14 colonies/100 ml
   - TSS concentration: $\leq$5 mg/L
   - TN concentration: $\leq$10 mg/L

   These standards are typically met by microfiltration and chlorination.

4. MADEP may not allow discharge of a chlorinated effluent into a Zone II area due the possible formation of disinfection byproducts. In this case, ultraviolet radiation disinfection would be needed.

These requirements and issues have been incorporated into the individual site evaluations and should be reviewed with MADEP to discuss potential permitting requirements.

Development and Comparison of Conceptual Effluent Discharge Designs

Infiltration Beds

Conceptual designs for sand infiltration beds were developed in accordance with the following guidance documents:

- *Guides for the Design of Wastewater Treatment Works, NEIWPCC*
- *Guidelines for the Design, Construction, Operation, and Maintenance of Small Sewage Treatment Facilities with Land Disposal* by the MADEP
- *Interim Guidelines on Reclaimed Water* by the MADEP

The following additional considerations were also used to develop the conceptual designs:

- Available areas were divided into cells approximately 200 feet by 200 feet in size in order to provide flexibility for operation and maintenance.
- Cell areas would be graded flat during construction and be separated by berms.
- Effluent flow would be pumped from the WPCF through the transport force main, into header pipes, and then into individual bed influent pipes.
- The header pipes would control areas of use, while the bed influent pipes would control flow to individual cells.
- Splashing would be prevented through the use of an end splash guard and pad. Pumping is only required at the WPCF.
- Header pipes and bed pipes are valved, allowing for individual cell use. Cell areas require 4 feet of clean sand for the infiltration surface. The site would contain access roads along the berms and the site area would be fenced.

Subsurface Infiltration Facilities

Conceptual designs for subsurface infiltration facilities were developed in accordance with the following guidance documents:

- *Guides for the Design of Wastewater Treatment Works, NEIWPCC*
- *Title 5 Pressure Distribution Guidance* from MADEP.
- *Interim Guidelines on Reclaimed Water* by the MADEP.

The following additional considerations were also used to develop the conceptual designs:

- Effluent flow would filtered at a new filter facility located (in the flow train) between the secondary clarifiers and the chlorine contact tank.
- If the effluent discharge is up gradient of a fresh water body and phosphorus removal is needed, the phosphorous would be precipitated and removed with the addition of a metal salt (alum, ferrous sulfate, etc) before the filter.
- The filtered effluent would be pumped from the WPCF, through the transport force main, and into a wet well and pump station located at the site.
- The effluent would be re-pumped through header piping, center manifold piping, and distribution piping in the infiltration cells. The header pipes control areas of use, while the center manifolds control the flow to individual cells.
- Infiltration areas are divided into cells approximately 200 feet by 200 feet in size in order to provide flexibility.
- Flows discharge from the distribution pipes located approximately 8 feet on center.
- Pumping is required at the WPCF and at the site.
- Header pipes and center manifolds are valved, allowing for individual cell use, periodic high-rate dosing, and the ability for cells to dry out between doses.

Spray Irrigation Facilities

Conceptual designs were investigated for spray irrigation facilities in accordance with the following guidance documents:

- *Interim Guidelines on Reclaimed Water* by the MADEP.
- *Guides for the Design of Wastewater Treatment Works, NEIWPCC*

The following additional considerations were also used to develop the conceptual designs:

- Hydraulic loading rate of 2 inches per acre per week.
- Nozzle spacing of 60 to 100 feet.
- Nominal nozzle pressure of 30 psi.

Each alternative conceptual design was developed as described below. Conceptual layout sketches are provided in Appendix A.

B1: The McManus site with sand beds. Approximately 7.5 acres would be available for effluent application and approximately 1.6 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include

the installation of a 12-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

B2: The McManus site with subsurface infiltration. Approximately 11.5 acres would be available for effluent application and approximately 0.9 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities and effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

C2: The Municipal Airport site with subsurface infiltration. Approximately 28 acres would be available for effluent application and approximately 2.3 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities and effluent pumps. Improvements along the route would include the installation of a 14-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

D1: The Cape Cod Community College site with sand beds. Approximately 8.1 acres would be available for effluent application and approximately 1.7 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

D2: The Cape Cod Community College site with subsurface infiltration. Approximately 15 acres would be available for effluent application and approximately 1.1 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities and effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

E1: The Lorusso site with site sand beds. Approximately 2.3 acres would be available for effluent application and approximately 0.5 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include the installation of a 8-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

E3: The Lorusso site with spray irrigation. Approximately 5.0 acres would be available for effluent application and approximately 0.04 mgd could be applied. Based on the limited application volumes, this scenario has not been developed further.

A summary of capital costs associated with each alternative is shown in Appendix B.

Comparison of each of the six alternatives (Sites B1 through E1) was performed based on the following criteria: available land area, estimated facility capacity, owner type, distance from the WPCF, soil permeability, site topography, depth to groundwater, abutting land use, aesthetic impacts, proximity to sensitive receptors, capital costs, O&M costs, present-worth costs, cost per mgd. Table 3 summarizes these findings.

SUMMARY AND RECOMMENDATIONS

Options **B1** (McManus site with sand beds) and **D1** (Cape Cod Community College site with sand beds) appear to be the most favorable of the alternatives evaluated. Advantages of these two alternatives include:

- They are the lowest cost alternatives on a dollar per flow basis.
- Each has an estimated capacity of over 1.5 mgd.
- They are located along the Route 132 corridor where road reconstruction and sewer installation is planned. If these projects are coordinated, the force main costs could be reduced.
- The sand bed technology is the easiest to maintain.

Disadvantages of these alternatives include:

- The sites are not completely owned by the Town; and therefore, the sites may not be available or could require long time periods to obtain.

- These sites are located in the Sandwich moraine, which is a geologic area of Cape Cod that is characterized by denser soils that do not allow water to infiltrate quickly. Geologic investigations performed during the preliminary investigations indicated sandy soils and adequate percolation rates. More extensive site testing will be needed if these sites are selected for new discharge facilities.

As discussed previously, USGS modeling of potential effluent discharges will be needed to investigate mounding impacts and potential groundwater recharge to freshwater bodies and public water supply wells. Additional site testing will also be needed to verify the hydraulic application rates that have been estimated. This is expected to be required as part of effluent discharge permitting or as part of the wastewater facilities planning and would include additional soil borings and
a hydraulic loading test.

We recommend that the findings of this evaluation be reviewed with the Citizens Advisory Committee and the owners of the properties to initiate the public education and decision-making process. Also, groundwater modeling with the USGS should be initiated as soon as possible to avoid delays in the evaluation of environmental impacts.

Please call with any questions or comments.

Very truly yours,

C	Airport Site	Total site area is 400+ acres. The focus area is 28 ac.	Town owned.	Access from State Route 28 (Iyannough Road) and Willow Street	Commercial Property, Undeveloped Property and Road ROW	8,600	No	No	Minimal	Medium to Course SAND	Glacial outwash plain, south of Sandwich Moraine	Urban Land with Carver Soils below	Mostly flat with a slight slope from northwest to southeast, grassed	38' to 44' above MSL	20' +/- during drilling; 14 to 18 feet after drilling.	3 tests with 2 minutes as maximum rate.	200 to 250 ft/day	South and southeast to Lewis Bay
D	Cape Cod Community College Site	Total site area is 70+ acres. The focus area is 27 ac.	State owned.	Access through Community College Property off Rte 6 Mid Cape Highway	Undeveloped, road ROW, and Community College.	15,500	No	No	In Historic District	3 areas: A: M-C SAND, large boulders, fill to 30". B:fill material to 4' with boulders. C: loamy sand	Sandwich Moraine	Plymouth-Barnstable Complex	Natural topography is irregular and undulating: tree vegetation	85' to 130' above MSL: Relief undulations of 25' +/-	65' to 70' +/-	2 tests: 1 @ 8.7 minutes, 1 @ 0.67 minutes	50 to 200 ft/day	North to Barnstable Harbor
E	Lorusso Site	Total site area is 12 acres	Privately owned.	Access from Industrial Blvd off of Kidd's Hill Road	State Roadway and Undeveloped	10,400	No	No	Minimal	Fill at eastern end (topsoil at 6', silt-clay layer at 6'); western property M-F SAND	Sandwich Moraine	Plymouth-Barnstable Complex with Eastchop loamy sand	Lightly vegetated, rolling terrain, disturbed site with powerlines overhead	80 to 120' above MSL	65'+/-	3 tests with 4.6 minutes as the maximum rate.	50 to 200 ft/day	North to Barnstable Harbor

Notes:
(1) As measured along proposed routing
(2) Sites fall into one of three categories
- In Historic District
- Potential = May contain historical artifacts of significance
- Minimal = Not viewed as a historical site due to its disturbed nature.

(3) Soil abbreviations
"M-C" is medium to coarse
"M-F" is medium to fine

TABLE 2

SUMMARY OF EFFLUENT DISCHARGE TECHNOLOGIES
Wastewater Facilities Plan
Town of Barnstable, MA

ALTERNATIVE	REGULATORY REQUIREMENTS	EFFLUENT QUALITY	MAINTENANCE REQUIREMENTS AND COMPLEXITY OF OPERATION	FLEXIBILITY	ENERGY USE	LAND REQUIREMENTS	POTENTIAL FOR AIR EMISSIONS	PUBLIC ACCEPTANCE	RELATIVE CAPITAL COSTS	RELATIVE O&M COSTS	SELECTED FOR DETAILED EVALUATION
1. Sand infiltration beds	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Effluent is already treated and sand beds provide some additional treatment.	Effluent discharge is reliable throughout the year and easy to maintain.	Flexibility is possible with multiple beds.	Lowest energy requirements due to no need to repump the effluent at the sand beds.	Moderate at large wastewater flows when compared to subsurface leaching.	Effluent is treated to a high level and odors would be minimal.	Potential for low acceptance from residents who are impacted by bed siting and construction.	Relatively low due low land area and easier construction.	Low due to low energy requirements and minimal maintenance.	Yes; the technology is simple and reliable. O&M requirements are minimal.
2. Subsurface infiltration	Disinfection is not required prior to discharge, unless required to meet the Interim Guidelines for Reclaimed Water Use.	Effluent is already treated and infiltration facilities provide additional treatment. Effluent should be filtered before discharge.	Repair of the beds would be difficult because they are subsurface	Moderate depending on construction of dosing equipment and distribution piping.	Moderate due to effluent dosing pumps.	Relatively high. Land surface above the infiltration system can be used for other purposes	Minimal.	Acceptance should be high due to minimal visual impacts and potential reuse of land area.	Relatively high due to highest land area and extensive piping.	High due to pumping requirements and potential high repair/cleaning costs.	Yes; technology is reliable and provides secondary use of discharge area.
3. Spray irrigation	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Spray irrigation provides further uptake of nitrogen in the effluent.	Moderate maintenance to maintain piping. Spray irrigation cannot be used in freezing weather.	Must have redundant back-up facilities for winter discharge.	Moderate due to repumping requirements.	Relatively high. Land above system can be can be used for other purposes when spray irrigation is turned off.	Minimal.	The public will want to see recycling of the effluent though they may be concerned about possible health threats.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to maintenance and pumping requirements.	Yes; it provides additional nitrogen uptake and reuse of the effluent.
4. Deep well injection	Permitting and monitoring of effluent discharges and design requirements. MADEP is not supportive of this technology.	Effluent must be well treated (filtered and chlorinated) before discharge.	Uncertain reliability due to few operating installations and increased maintenance due to the potential of plugging of injection point with solids.	Installation of multiple wells would allow individual wells to rest or be repaired.	Moderate due to repumping requirements.	Relatively low compared to sand infiltration beds and subsurface leaching.	Minimal.	Land area requirements and visual impacts are minimal.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	No; MADEP is resistant to support the technology due to the need to chlorinate the effluent

Mr. Mark Giordano, P.E.
Senior Project Manager
Department of Public Works
Town of Barnstable
367 Main Street
Hyannis, MA 02601

Re: Preliminary Evaluation of McManus Property
S&W No. 20054
Final Report

Dear Mr. Giordano:

The Town of Barnstable has asked Stearns & Wheler to complete an evaluation of the McManus site to determine its suitability for wastewater reclamation through groundwater recharge. The evaluation was completed in accordance with the Barnstable Wastewater Facilities Plan (WWFP) recommendation to identify and utilize remote sites for the purpose of recharging treated wastewater to the subsurface. The initial Scope of Work for the investigation included:

- An initial screening of the site based on siting criteria used previously by the Town to identify and evaluate sites
- Completion of eight test pits
- Installation of two soil borings and, if warranted, two observation wells
- Completion of percolation tests and slug tests

The scope of work was adjusted based on field conditions. Access restrictions limited the number of final test pits to six and the number of borings and wells to one.

The balance of this letter report is comprised of four sections, which will discuss:

- Project Background
- Location Considerations
- Site Characteristics
- Conclusions

PROJECT BACKGROUND

The Town of Barnstable is in the process of completing a Wastewater Facilities Plan (WWFP) that evaluates future options for the Town to collect, treat and dispose of municipal wastewater. A component of the WWFP called for the identification of parcels of land, remote from the existing Water Pollution Control Facility (WPCF), where treated wastewater can be reclaimed by discharging it back to the subsurface in order to replenish groundwater resources in the Town. In the course of completing the WWFP, the Town undertook a remote site screening process to identify areas of the Town where suitable parcels may exist. Following the completion of that screening process, the Town began to identify specific parcels that could be further evaluated for suitability. The first of those parcels is the McManus property.

The subject parcel is located just south of the intersection of Route 132 (Iyanough Road) and Route 6 (Mid-Cape Highway). The parcel is located approximately 1,100 feet south of the intersection on the north side of Route 132 and is approximately 8,100 feet form the WPCF. It is trapezoidal in shape and occupies 6.63 acres. The location of the parcel is shown on Figure 1.

During this evaluation of the parcel, two different sets of characteristics were reviewed; characteristics associated with the location of the property and physical characteristics of the property itself. The location and site characteristics are discussed below.

LOCATION CONSIDERATIONS

Location considerations relate to the suitability of the site based on its setting. These criteria were evaluated by the Town in their initial screening process and included such factors as location relative to:

- Wellhead Protection Area
- Areas of Critical Environmental Concern
- Hyannis Coastal Plain Complex
- Vernal Pools
- Wetlands
- Areas of rare and endangered plant and wildlife habitat
- Conservation Areas
- Flood Hazard Zones
- Drainage basins

The results of that screening process indicated that:

- The McManus property is immediately adjacent to but not in an area identified as Area B, one of three sections of the Town that the 1998 site screening effort determined was appropriate for further evaluation of sites.
- The McManus property is located on the western edge of the Zone of Contribution of Barnstable Fire District Well #3, located approximately 3,000 feet to the south east of the McManus property.
- The McManus property is not in an Area of Critical Environmental Concern or an area excluded from wastewater discharge based on proximity to ponds, wetlands or coastal water.
- The McManus property has not been previously identified to be in areas of rare or endangered species or in a restricted wildlife habitat.
- The McManus property has not been previously identified as being in a conservation area or a Flood Hazard Zone.
- The McManus property is in an area that, based on current Town mapping, may drain toward Barnstable Harbor, to the north.

SITE CHARACTERISTICS

Published Information

Geologic Setting. The site is located on the Sandwich Moraine, a glacial deposit that is characterized by slopes and hills and heterogeneous soil comprised of sand, silt, clay, gravel cobbles and boulders. Location on the moraine also suggests more variable topography than would be found on the more southerly outwash plains.

Soil Type. The specific soil type at the site is mapped as the Plymouth-Barnstable complex, characterized as rolling and bouldery. These soil types are found on the side slopes of moraines. The surficial material is black, decomposed organic material overlying loamy sand, which is underlain by light yellowish brown, course sand (USDA, SCS, 1993).

Site Topography. The site is characterized by irregular topography. Even within the six acre parcel, there are a number of undulations with relief of approximately 20 feet.

Depth to Groundwater. The McManus property is in an area where groundwater has been mapped to be greater than 10 feet below the surface.

Hydraulic Conductivity. The McManus property is in an area where previous modeling efforts (Geraghty & Miller) assigned a hydraulic conductivity of 75 feet per day. The WWFP suggests that areas with hydraulic conductivities greater than 200 feet per day could be considered as viable recharge sites. Although this suggests that the site may not be ideal, both of these factors (the mapped hydraulic conductivity and the 200 foot per day criteria) are generalizations that should not, in themselves, rule out a site from further consideration.

Field Investigation Results

Test Pit Observations. On March 15, 2002 six test pits were excavated on the property. Test pit locations are shown on Figure 2 and test pit logs are attached. Test pit TP-6 was proposed further to the north but several attempts in that area indicated the presence of fill material rather than native soil. Test pit TP-6 was therefore located toward the south. The observations made of the test pits confirmed the general soil types presented in the SCS descriptions. A sequence of sandy loam to loamy sand to fine sand was observed in most of the test pits. In one of the test pits (TP-4) some silt was observed at the depth from 5 to 7 feet. Although the soils are characterized as bouldery, and some boulders are observed on the surface, none were encountered in the test pits. In some instances, cobbles up to 6 inches in diameter were encountered. The general observation from the test pits is that the prevalent soil at the site is sand. Groundwater or the indication of seasonal high groundwater was not observed in the test pits.

Percolation Tests. Percolation tests were conducted at four of the six test pits (TP-1, TP-3, TP-5 and TP-6) to obtain a generally qualitative assessment of the soil's capacity to allow water to infiltrate. Percolation test logs are attached. Percolation rates are compared to standards in "Guidelines for the Design Construction, Operation and Maintenance of Small Sewage Treatment Facilities with Land Disposal". Percolation rate at two of the test pits (TP-1 and TP-3) was 3 minutes per inch. At TP-5 the percolation rate was 1.33 minutes per inch and at TP-6 the percolation rate was 4.33 minutes per inch. According to the referenced guidance, percolation rates under 5 minutes per inch should allow the application of 5 gallons per day per square foot (gpd/sq ft). If the recharge facility has a design capacity of 500,000 gpd, 2.3 acres of sand beds would be needed. Additional, back up acreage would also need to be considered. If

trenches are being considered as a recharge mechanism, approximately 33,000 linear feet of trenches would be required if each linear foot of trench represents 6 square feet of infiltration area.

Deep Boring Observations. One deep soil boring was installed at the site to characterize deep soil conditions and to determine the depth to ground water. Because the soil character was generally favorable, the soil boring was completed as a test well. The soil boring was advanced to a depth of 85 feet. A soil boring log is attached. Virtually the entire 85 foot soil section penetrated was comprised of yellow-brown fine to coarse sand. As the boring was advanced, the sand became more and more tightly packed. Near the top of the boring, blow counts from 4 to 30 blows per 6-inch section were observed. In deeper sections of the boring, blow counts ranged from 60 to 100 blows per six inches, indicating a much more tightly packed matrix. Despite the tight nature of the material, it remained a generally clean, fine to coarse sand. At the bottom of the boring, two feet of light brown, silty clay was penetrated.

When the well was completed, the depth to groundwater was measured and found to be 58 feet below the ground surface.

Deep Hydraulic Conductivity. A slug test was completed in the test well to estimate hydraulic conductivity of the underlying formation. The slug test indicated the formation hydraulic conductivity to be approximately 1 foot/day. This measurement was confirmed by duplicating the test two additional times. Although this is a low value for relatively clean sands, it is within the range of hydraulic conductivities reported for fine sand (Fetter, 1994). Also, a slug test is a very preliminary and generalized means of determining hydraulic conductivity. It measures the conductivity only in the very immediate vicinity of the well bore and may not necessarily be representative of the formation as a whole. (Note: Public supply wells located south east of the site produce approximately 700 gallons per minute, suggesting a higher hydraulic conductivity, at least in that area. The Barnstable Fire District is attempting to locate hydraulic conductivity data for the project that may have been developed at the time of installation of those wells.)

CONCLUSIONS

The candidate site is comprised of approximately six acres.

It is located in a groundwater protection area and on the flanks of a Zone of Contribution of a Barnstable Fire District Well. DEP does not exclude reclamation/recharge within a Zone of Contribution but has set a standard of a two year travel time for groundwater flow from the recharge area to a public supply well. Based on the flat gradient and the Geraghty & Miller hydraulic conductivity for the area, flow rate has been preliminarily

calculated to be .225 feet per day or 164 feet in two years. Also, groundwater flow direction is presently mapped to be toward the east-northeast, not toward the wells.

The candidate site is not located in any other excluded areas identified during the site selection screening process.

The site has irregular topography, which would complicate but not prevent the use of the site for recharge facilities.

The site is located 8,100 feet from the WPCF. The distance, in itself, is not an advantage or disadvantage, until compared to the distances of other candidate sites.

The subsurface soils are comprised primarily of fine to coarse sand. Some cobbles were observed in test pits and a silty zone was observed in one of the test pits. A clay layer was encountered at 85 feet in the test boring.

Percolation rates of less than 5 minutes per inch were obtained, suggesting suitable soils for recharge near the surface.

Deeper sands (>30') are extremely dense as indicated by blow counts in the 60 – 100 counts range. The density of the deeper sands was supported by a relatively low hydraulic conductivity, as indicated by the slug tests.

Using an analytical mounding calculator used by MADEP for evaluating mounding at water recharge sites (Hantaxis®) and the measured hydraulic conductivity of 1 foot/day, a disposal rate of approximately 100,000 gpd over a 3 acre area would result in a calculated mound of approximately 50 feet, significant, but acceptable. Again, the measured hydraulic conductivity may not be representative of the formation. If a more reasonable estimate of hydraulic conductivity is assigned, (the Geraghty & Miller estimate of 75 feet/day) the site can accept 500,000 gallons per day with a resultant mound of approximately 12 feet. Further investigation of the hydraulic conductivity is warranted.

To conclude, the site has the advantages of proximity to the WPCF, not being located in exclusion areas and of being comprised of relatively clean sand. The site has the disadvantages of having irregular topography, of presumably draining to the north toward Barnstable Harbor, and of having potentially low hydraulic conductivity in the deeper sands, although the measured value may not necessarily be representative of the formation material. The disadvantages identified so far are not enough to eliminate the site from further consideration and the site should be considered a viable remote

discharge site. Additional testing to verify this conclusion would be required during the permitting process

If you have any questions regarding the procedures or interpretations presented in this letter, please call.

Very truly yours,

Re: Effluent Mitigation Investigation Project
Task 1 - Airport Investigation
S&W No. 20190.0
Final Report

Dear Mr. Giordano:

In accordance with your request and the Contract for Consultant Services for the Effluent Mitigation Investigation Project Task 1 – Airport Characterization, we have completed a preliminary evaluation of the Barnstable Municipal Airport for the recharge of treated effluent. In accordance with paragraph 2.2.5.2 of the Contract for Consultant Services, QA/QC procedures of the Scope of Work were adhered to in the completion of this project. The evaluation was completed consistent with the Barnstable Wastewater Facilities Plan (WWFP) recommendation to identify and utilize remote sites for the purpose of recharging treated wastewater to the subsurface.

BACKGROUND INFORMATION

The Town of Barnstable is in the process of completing a Wastewater Facilities Plan (WWFP) that evaluates future options for the Town to collect, treat and dispose of municipal wastewater. A component of the WWFP called for the identification of parcels of land, remote from the existing Water Pollution Control Facility (WPCF), where treated wastewater can be reclaimed by discharging it back to the subsurface in order to replenish groundwater resources in the Town. Utilization of remote sites for the recharge of treated wastewater was recommended because the WWFP and related work concluded that the recharge capacity of the existing plant is limited due to potential adverse impacts resulting from groundwater mounding. In the course of completing the WWFP, the Town undertook a remote site screening process to identify areas of the Town where suitable parcels may exist. Following the completion of that screening process, the Town

began to identify specific parcels that could be further evaluated for suitability. The second of those parcels being investigated is the Airport property. Reference is made to Figure for the location of the Airport property.

The subject parcel is located at the intersection of Route 132 (Iyanough Road) and Route 28, north of the "Airport Rotary". The location of the Airport is shown on Figure 1. Three candidate areas were identified at the Airport. The three candidate areas are located just to the northwest of the intersection of the two runways in the southern section of the facility (Candidate Area A), in the northeast corner of the facility (Candidate Area B), and in the northwest corner of the facility (Candidate Area C). Candidate area locations are shown on the Airport Site Map, Figure 2.

SCOPE OF WORK

The Scope of Work for the investigation included the following tasks:

Subtask 1.1 Site Visit. Prior to initiating site work on the site, an initial reconnaissance trip to the site was conducted. A Massachusetts Department of Environmental Protection (MADEP) representative was requested to attend this reconnaissance trip to refine boring and test pit locations and to provide preliminary opinions regarding the suitability of the site. MADEP received a seven-day notification of the site visit. MADEP provided input to the plan to utilize the Airport for wastewater discharge but opted not to be involved in any site visits. Additionally, discussions were held with site owners. The purpose of these discussions was to determine what restrictions (Federal Aviation Administration (FAA) or otherwise) could impact investigative efforts or future use of the site.

Subtask 1.2 Initial Screening. Following the site visit, an initial screening was completed that evaluated the suitability of the site in terms of siting criteria considered in earlier phases of the site identification and screening process, including but not limited to location with respect to:

1. In Wellhead Protection Zones I, II and III
2. In Areas of Critical Environmental Concern
3. Near vernal pools
4. Near wetland
5. In areas of rare and endangered plant and wildlife habitat
6. In conservation areas
7. In flood hazard zones
8. Releases of oil or hazardous materials

9. Drainage basin

Under this subtask, Stearns & Wheler did not redo the Town's earlier screening efforts but refined and updated the previous work.

Subtask 1.3 Test Pits. Nine (9) backhoe test pits were completed at the site. Three test pits were dug in each candidate area. Test pits were excavated to a depth of 8 to10 feet. A soil evaluator logged soil stratigraphy in the test pits. A percolation test was completed at one test pit in each area. Test pit locations are shown on Figure 2.

Subtask 1.4 Soil Borings. Three (3) soil borings were drilled to a depth 50 feet each. The proposed work plan specified the borings would be advanced to a depth up to 90 feet. Based on field observations, including the observation that the water table was encountered at a depth of less than 20 feet, the borings were advanced to a depth of 50 feet. One soil boring was installed in each of the three candidate areas. Split spoon samples were collected at 5 foot intervals from each boring. Stearns & Wheler recorded soil types on a boring log. Boring locations are shown on Figure 2.

Subtask 1.5 Observation Wells/Slug Tests. Upon completion of the first soil boring, a field determination was made that the site is a likely candidate for disposal, so the soil borings were completed as observation wells. In-situ hydraulic conductivity testing (slug testing) was attempted in each well to determine the permeability of the deeper soils. This data was needed in order to complete a groundwater mounding analysis, a requirement of a groundwater discharge permit application, should the Town decide it wants to pursue a permit for this parcel. Slug test results were determined to not be representative of the soil conditions at the site and were disregarded. The evaluation was therefore based on hydraulic conductivity values used by USGS in their current modeling efforts in the area. Additionally, the elevations of the wells were surveyed, water levels were measured, and the groundwater flow direction was determined.

Subtask 1.6 Report of Findings. A written report for the Town that presents the field investigation results and provides recommendations regarding the use of the subject parcel for treated effluent disposal is included herein.

Subtask 1.7 Meetings. Time was allocated for meetings related to this site investigation. One meeting where preliminary results were presented was held on January 16, 2003. An additional meeting is anticipated.

EVALUATION RESULTS

The results of the Airport Investigation are presented in this section. The results are organized in the following order:

- Location Considerations.
  - Summary of initial site screening considerations and results
- Site Characteristics
  - Published Information from literature about the general characteristics of the area of the site.
  - Field Investigation Results – detailed results from the Stearns & Wheler field investigation.

Location Considerations

Location considerations relate to the suitability of the site based on its setting. These criteria were evaluated by the Town in their initial screening process and included those factors listed in the introduction section of this letter. Stearns & Wheler reviewed and updated these siting criteria.

The results of that screening process indicated that:

1. There are several Public Water Supply production wells located on or adjacent to the Airport property, the Barnstable Water Company operates BWAIR #1, three (3) Mary Dunn (BWMD) wells north of the Airport and three (3) Maher (BWMEL) wells southeast of the Airport.

2. The Barnstable Fire District has a well, BFD #2 north of candidate area C, but this well is presently inactive.

3. The three (3) candidate areas at the Airport are in Town designated Groundwater Protection Zones and in the Approved Zone IIs of the proximal production wells. The candidate areas are in or immediately adjacent to Town designated Wellhead protection districts. (See Attachment A Map – Barnstable GIS Map of Groundwater Protection Areas and Wellhead Protection Areas).

4. The Airport property is not in an Area of Critical Environmental Concern based on GIS mapping provided by the Town.

5. The Airport property is adjacent to but not included in a Natural Heritage Endangered Species Priority Site. (See Attachment B Map – MADEP Bureau of Waste Site Cleanup – Map showing sensitive environments).

6. The Airport property has not been previously identified as being in a conservation area or a Flood Hazard Zone.

7. The Airport property is in an area where, based on current Town mapping, groundwater flows to the southwest.

8. Presence of the candidate sites within Zone IIs of production wells will define the recharge of treated wastewater as reclamation as defined in the DEP guidance Interim Guidelines on Reclaimed Water. This will necessitate additional water quality and monitoring requirements. These requirements are summarized on an excerpt from the cited Guidelines, included as Attachment C.

Site Characteristics

1. **Published Information**

a. Geologic Setting. The site is located on the glacial outwash plain south of the Sandwich Moraine. Well-sorted sand and gravel deposits characterize the outwash plains, formed by glacial melt water.

b. Soil Type. The surficial soils at the Airport are defined as Urban Land (USDA, SCS, 1993). This implies that the soils have been altered or obscured by anthropogenic activity. At the Airport, it is evident that the area to accommodate the runways has been cut or filled to make it level. Underlying the disturbed soils the Carver Soils are present. The Carver Soils are characterized as well drained, outwash plain, course sand.

c. Site Topography. The Airport site is essentially flat. Although it has been graded to accommodate construction of the Airport, it is in an area that has very little relief naturally.

d. Depth to Groundwater. The Airport property is in an area where groundwater has been mapped to be greater than 10 feet below the surface.

e. Hydraulic Conductivity. The Airport property is in an area where current USGS modeling efforts are using a hydraulic conductivity of 200-250 feet per day. The WWFP suggests that areas with hydraulic conductivities greater than 200 feet per day can be considered to be viable recharge sites.

2. Field Investigation Results

Each of the three candidate areas was investigated in the same manner, with three test pits, a percolation (perc) test, and a soil boring advanced to 50 feet. Each boring was completed as an observation well. A detailed description of the field investigation follows.

a. Test Pit Observations. On January 10, 2003 nine (9) test pits were excavated on the property. Three test pits were excavated in each of the three candidate areas. Test pits were excavated to depths ranging from 8 to 12 feet. Test Pit Logs are included as Attachment D. Medium to course sand was observed in all of the test pits. Groundwater was not observed in the test pits. Some soil mottling was seen at a depth of 7 feet in area A, at 4-5 feet in Area B and at 2 – 3 feet in Area C. The mottling may be indicative of possible high groundwater although the mottling is not particularly consistent or obvious.

b. Percolation Tests. Percolation tests were conducted at one test pit in each candidate area to obtain a generally qualitative assessment of the soil's capacity to allow water to infiltrate. Percolation test logs are included as Attachment D. Percolation rates are compared to standards in "Guidelines for the Design Construction, Operation and Maintenance of Small Sewage Treatment Facilities with Land Disposal". Percolation rate at each of the three test pits was 2 minutes per inch. According to the referenced guidance, percolation rates under 5 minutes per inch should allow the application of 5 gallons per day per square foot (gpd/sq ft).

c. Deep Boring Observations. One deep soil boring was installed at each candidate area to characterize deep soil conditions and to determine the depth to ground water. Because the soil characteristics were favorable, each boring was completed as a test well. Each soil boring was advanced to a depth of approximately 50 feet. The depth of the borings was decided in the field as the borings were advance and when groundwater was encountered at a depth of approximately 20 feet in each boring. Advancing the borings to 50 feet allowed a 30 feet section of the aquifer to be evaluated. Soil boring logs are included as Attachment F. Virtually the entire 50-foot soil section penetrated was comprised of yellow-ish white to tan, medium to coarse sand. In boring OW-B, a silt and clay layer was encountered between 43 and 48 feet. This layer was not seen in the other two borings and is not believed to be continuous across the area.

On March 12, 2003, depth to water was measured in the three observation wells. Water depths were:

- 18.14 feet below grade in well OW-A
- 14.17 feet below grade in well OW-B
- 17.36 feet below grade in well OW-C

d. Deep Hydraulic Conductivity. The evaluations in this investigation have been based on a hydraulic conductivity value of 200 feet per day as is being used by the USGS for their present modeling efforts in this area.

e. Groundwater Flow Direction and Rate. Groundwater flow direction and rate are germane to this study to assess the extent to which treated effluent will flow toward proximal production wells and to determine whether recharge facilities would be located within a two year travel time of the production wells.

Depth to water measurements and the calculated groundwater elevations indicate a groundwater flow direction consistent with the regional mapping, toward the southeast. This would indicate flow toward the Barnstable Water Company Maher wells. The Maher wells are located approximately 2,250 feet from candidate area A, 5,000 feet from candidate area B and 6,250 from candidate area C.

Although they are not directly downgradient , the Mary Dunn Wells and the Barnstable Water Company Airport Well No. 1 may be closer to the candidate areas. Water could potentially be drawn to those wells also, as a result of their cones of depression.

Using a water table gradient of .0014 feet/foot, (based on the gradient determined to exist between candidate area C and candidate area A), a hydraulic conductivity of 200 feet per day and an estimated aquifer porosity of 20%, a groundwater flow rate of 1.4 feet per day has been calculated. Travel time from each candidate site to proximal production wells is summarized on Table 1.

Pumping from the wells likely results in a cone of depression around the wells, increasing the gradient. However, that impact either (1) does not reach the candidate sites and therefore there is a several year travel time between the candidate sites and the cone of depression, or (2) the resultant gradient is that which was observed and was used in the calculation. Either way, travel time to the production wells can be concluded to be in excess of two years.

f. Potential Mounding. Because the depth to groundwater is approximately 15 feet below grade at the Airport, a preliminary mounding analysis was completed to verify that

discharge at the Airport was feasible with respect to mounding. Using an analytical mounding calculator (the Hantaxis program, used by MADEP to calculate mounding impacts), a variety of discharge scenarios were run. The various scenarios tested different flow rates applied to the appropriate area (based on a discharge rate of 5 gpd/sq ft). A hydraulic conductivity value of 200 feet per day was used in the simulations. The results of the preliminary mounding analysis are presented on Table 2.

The preliminary mounding analyses indicate that if the site has a hydraulic conductivity around 200 feet per day, and maximum high groundwater conditions are considered, that the each candidate site can handle a flow of up to approximately 1 mgd. At that application rate groundwater levels at the discharge site were calculated to be within 7 feet of the surface but the mounding drops off in close proximity to the discharge site.

leaching field only?

CONCLUSIONS

The Airport has a number of qualities making it suitable for wastewater recharge. These include:

1. The Airport is a Town owned facility consisting of approximately 418 acres in its main, developed sections. Large sections of the Airport are cleared, unused, and potentially available for the construction of recharge facilities that are at or below grade.

2. The subsurface material is comprised of clean, uniform, medium to fine grain sand, providing an ideal infiltration matrix.

3. High hydraulic conductivity values are indicated by the presence of several public supply wells in the area that can produce from 500 to 1,000 gallons per minute. A value of 200 to 250 feet per day is being used by the USGS to complete groundwater modeling in this area.

4. Groundwater travel time from candidate area A in the southern portion of the Airport to the nearest downgradient wells is greater than the 2 year time considered significant in the state's reuse policy.

5. The site has little to no relief (essentially flat) and is cleared, which would simplify the construction of facilities.

6. The site (candidate area A) is located 6,800 feet from the WPCF. The distance, in itself, is not an advantage or disadvantage, until compared to the distances of other candidate sites. This is the closest candidate remote site presently being considered.

7. Percolation rates of 2 minutes per inch were obtained, suggesting suitable soils for recharge near the surface.

8. There are also some potential limitations or restrictions to using the Airport property. These include:

9. Federal Aviation Administration (FAA) and Airport regulations will strictly limit construction activities, above grade structures, and locations of facilities. Discussions with Airport personnel suggest that proper design of new facilities that take these considerations into account could be allowed with FAA and Airport approval. Specific restrictions at this time include no construction of any kind within 150 feet of the center of the runways (the Buffer Zone). Beyond the Buffer Zone is the "Obstacle Free Zone" that extends 500 feet from the center of the runway. In this zone there can be no vertical obstructions (such as berms). The Obstacle Free Zone extends 1,000 feet off the ends of the runways.

10. No construction can be planned or undertaken until the Airport completes its plans for redesigning the layout of the Airport, which is a project currently underway by the Airport. The design is expected to be finished near the end of 2003.

11. Although there do not appear to be any conditions that specifically exclude the construction of recharge facilities, there are a number of sensitive environmental issues that would most likely have to be considered during the MEPA review and permitting process including:

    - proximity of water supplies;
    - proximity of groundwater contamination that could be impacted by mounding; and
    - proximity of a Natural Heritage Priority Site which is designated because of the pond habitats located in the central portion of the Airport. Impacts to water levels in those ponds could impact the protected species.

12. Groundwater is relatively close to the surface (15 to 20 feet), which could limit discharge rates.

To summarize, the Airport has the potential to be an ideal site to discharge treated effluent. There would be restrictions related to location and construction activities but it

appears those could be managed. Soil type, topography, distance from sensitive receiving waters, and proximity to the WPCF all contribute to this conclusion.

If the Town elects to pursue the Airport as a remote discharge site, Stearns & Wheler recommends the following course of action.

- Develop a conceptual design of a disposal facility in terms of type and size.
- Meet with FAA and Airport to discuss the feasibility of constructing such facilities and what restrictions or limitations would have to be considered, and to discuss incorporating the Town's plans into the Airport's redevelopment plans.
- Based on further discussions with USGS, consider obtaining refined hydraulic conductivity data by completing a pumping test at the site.
- Refine the facility design based on flow rates and Airport and FAA limitations.
- Incorporate the Airport site into the Facilities Plan MEPA/EIR process concurrently with pursuing a Groundwater Discharge Permit for the site.

Please call with any questions or comments.

Very truly yours,

Excerpt From Interim Guidelines on Reclaimed Water

Type of Reuse - Indirect Aquifer Recharge - Discharges into aquifer recharge areas as defined by Zone II boundaries and groundwater discharges that will recharge reservoirs or tributaries to reservoirs. Required Treatment Level . secondary[4] . filtration (possibly)[5] . disinfection[6]	Discussion Attached
Required Reclaimed Water Quality[2] . pH 6 – 9 . BOD - ≤ 10 mg/l or ≤30 mg/l . ≤ 2 NTU or ≤ 5 NTU . fecal coliform – median of no detectable colonies/100 ml over continuous, running 7 day sampling periods, not to exceed 14/100 ml or 200 colonies/100 ml . TSS - 5 mg/l or 10 mg/l . Total Nitrogen - < 10 mg/l . Class I Groundwater Permit Standards (SDWA Drinking Water Standards)[10]	Required Reclaimed Water Monitoring . pH - weekly or daily . BOD - weekly . Turbidity - continuous . Fecal coliform - daily or 2/week • Metals -quarterly, TSS - weekly or 2/week . Nitrogen - 1 or 2/week • MS-2 phage - quarterly • Total culturable viruses - quarterly . Variable testing requirements 0 Disinfection UV intensity - daily or chlorine residual - daily
Comments New treatment plants located in approved Zone IIs with less than a two year groundwater travel time to the public water supply well must treat to the more rigorous of the two standards listed above. Existing treatment plants that can demonstrate the four or five feet of separation and where the well has not shown any evidence of water quality degradation, may maintain the lesser standard. Massachusetts Drinking Water Program waivers reducing the required sampling of Public Water Supply Wells will not be issued if there are permitted Groundwater Discharges in the Zone II. Treatment plants that meet the criteria listed above are considered to be improvements over unsewered Title 5 systems as it pertains to SDWA Susceptibility Assessments.

Senior Project Manager
Department of Public Works
Town of Barnstable
367 Main Street
Hyannis, MA 02601

Re: Effluent Mitigation Investigation Project
Task 3 - Benchmark Evaluation
Final Letter Report

Dear Mr. Giordano:

This letter presents the findings of an evaluation to determine the next Benchmark Elevation at which potential impact due to groundwater mounding may occur at parcels in the vicinity of the Hyannis Water Pollution Control Facility (WPCF). This evaluation is a component of the Wastewater Facilities Planning (WWFP) and Environmental Impact Report (EIR) Project that the Town of Barnstable (Town) is currently completing. The primary objective of this evaluation is to determine the amount of wastewater that can be discharged at the Hyannis WPCF on a maximum monthly flow basis without causing potential flooding to structures or septic systems due to resultant groundwater mounding. In accordance with paragraph 2.2.5.2 of the Contract for Consultant Services, QA/QC procedures of the Scope of Work were adhered to in the completion of this project. In accordance with paragraph 2.2.5.4 of the Contract, Stearns & Wheler is providing five (5) bound copies, one (1) unbound copy, and one computer copy of this report.

EXECUTIVE SUMMARY

The need to evaluate effluent management alternatives in the WWFP became evident when work conducted by Geraghty & Miller (G&M) (1992, 1995) concluded that it was possible that mounding, in conjunction with naturally high groundwater occurrences,

could potentially increase groundwater in the vicinity of structures or septic systems at properties within a one-mile radius of the Hyannis WPCF. As a result of the G&M work, the first Benchmark Elevation was identified as the rising of groundwater to a depth less than eight feet below grade (G&M, April, 1995). However, our findings conclude that groundwater rising to that level did not necessarily result in the flooding of buildings nor did it produce evidence that septic systems would become inoperable. It is possible for groundwater to rise to a level less than eight feet from the surface without flooding structures or disrupting the operation of septic systems at the properties of concern.

The first Benchmark Elevation was identified in 1995 as 36.26 ft above mean sea level (msl) at a property located approximately 800 feet east of the Hyannis WPCF previously known as Nevada Bob's but now under new ownership. While under its previous ownership, the basement of Nevada Bob's was filled in with cement to mitigate flooding. Based upon the modeling work of G&M and actual observed evidence, the Town has further identified and mitigated parcels that had the potential of flooding from groundwater mounding resulting from effluent discharge at the Hyannis WPCF site. Other susceptible buildings have either been demolished or the owner's have negotiated with the Town for easements on the property to allow increased groundwater levels on the property.

The mitigated parcels include:

- Christian Center on Route 28 (easement)
- The Medieros property on Enterprise Road (easement)
- A residence on St. Francis Circle (purchase)

The goal of this evaluation was to identify the next Benchmark Elevation/Location and to identify the effluent discharge rate at the Hyannis WPCF that could substantially reduce the potential for flooding to structures or septic systems This evaluation is based on a monthly flow which is the average of daily flows during that month. The maximum month is the largest of the monthly averages for the period of record used. The maximum

monthly flow at the Hyannis WPCF usually occurs in July or August. Daily flows may be greater than the monthly flow.

It should be noted here that the discharge rate that would result in the Benchmark Elevation being exceeded is primarily based on the condition of groundwater being at its highest elevation naturally. The level of the groundwater, without any contribution from the plant flow, could result in the flooding of basements or first floors of buildings.

Previous evaluations by G&M were primarily based on theoretical modeling with limited verification based on historical groundwater elevation data. This evaluation builds upon the previous G&M work and has been further refined using groundwater elevation data that has been collected between 1992 and 2002. The historical data analysis has been used for comparison to the predictions used in the Benchmark Elevation determination process to evaluate:

- The accuracy of the Frimpter Belfit adjustment at this particular setting;
- The accuracy of the predictions made by the G&M modeling; and
- The precision of the predictions made by the G&M modeling.

The evaluation concluded that:

- An approximate 6.0 foot Frimpter Belfit adjustment is generally accurate however, this is a generalization of a range of values.
- The model is generally conservative, predicting higher groundwater elevations than actual observed conditions.
- The model is generally accurate in its predictions, with predicted water elevations generally being within 0.7 to 2.4 feet of actual conditions.

- The results of the model are not precise. The precision should be adjusted to be plus or minus six inches, therefore within a one foot range, rather than using exact values for elevation comparisons.

Although the model is reasonably accurate, many assumptions and generalizations are applied in its use. The model generally predicts the elevation of groundwater quite well. What the model cannot do is predict whether flooding of basements or first floor elevations are occurring. For example, based on the G&M model, there are several areas within a one-mile radius of the Hyannis WPCF that the model predicts flooding of basements at an effluent discharge rate of 1.0 MGD or less. However, operational history shows that during the spring of 1998, with a discharge of up to 2.0 MGD, and maximum high groundwater, that only isolated structures showed evidence of water seeping into basements. It is important to note that during this period in the area of St. Francis circle where one house had basement flooding, the Barnstable Water Company reported a water main break (north of the property) that was experiencing an estimated discharge of 0.5 MGD over an extended period of time.

Comparing observations of actual conditions during a high groundwater event to model predictions makes it reasonable to conclude that while being generally accurate, the G&M model should not be used to precisely predict when and where an impact will occur. It can be used as a predictive tool to identify potentially susceptible areas, but it cannot be used to predict the flooding of structures or causing disruptive operations of septic systems.

These conclusions lead to a recommendation that the Hyannis WPCF can continue to discharge on a maximum month basis between 2.3 and 2.5 MGD (the current maximum monthly flows). Due to natural fluctuations in the groundwater (similar to the elevations experienced in the spring of 1998), potential flooding of structures may occur. The discharge of flows greater than the current maximum monthly flows during periods of high groundwater may contribute to potential flooding of structures or septic systems. Based on historical observations and the previous mitigating efforts by the Town, this risk may be low, however, there is still a risk. The Town should develop a risk management strategy that would address potential flooding of structures during high groundwater

periods when concurrently the Hyannis WPCF is discharging greater than the current monthly maximum flows.

As a result, Stearns & Wheler recommends that the Town immediately begin the process of developing remote discharge sites to accommodate wastewater flows from: Areas of Concern identified in the WWFP (specifically Area H-1, Lake Wequaquet and the Cape Cod Community College); Chapter 40B Affordable Housing developments; and, infilling within the existing sewer service area. Based on an acceptable risk management strategy, the Town could move forward with these projects, but should not do so until a remote site (or sites) have been identified to be technically feasible and available to the Town.

It is also recommended that the Town use wells within its current groundwater monitoring program as part of an effluent discharge management system. Based on groundwater elevations, decisions could be made as to when it would be necessary to transfer flows to remote sites.

This letter report presents Stearns & Wheler's detailed evaluation and is comprised of the following sections:

- Benchmark Elevation Background
- Preliminary Evaluations
- Identification of Benchmark Elevation and Location
- Conclusions
- Recommendations
- Attachment – Detail Presentation of Project Scope – Preliminary Evaluations – Sensitivity Analysis

The information conveyed in this letter report will be integrated into the Final WWFP Report.

BENCHMARK EVALUATION BACKGROUND

Previously in the course of developing the Wastewater Facilities Plan, the Benchmark Elevation was defined as the water table elevation that could flood the basement of the former Nevada Bob's building located approximately 800 feet east of the Hyannis WPCF. The Benchmark Elevation was defined as 36.26 feet at that location, as measurable in well 92-16, located just outside of Nevada Bob's. Since that determination was made, that building's basement has been filled in. Other buildings, previously identified as potentially flooded along Enterprise Road, have been modified to mitigate this. In addition, the Town has negotiated a high water easement on the Medieros property on Corporation Road and on the Christian Center property on Route 28. The risk of flooding those properties near Enterprise Road has been eliminated through these recent effluent mitigation efforts. Therefore, other potentially flooded parcels and the maximum effluent discharge rate at the Hyannis WPCF that could contribute to the flooding during high groundwater periods needed to be identified. Susceptible areas identified are shown on Figure 1, a map of the study area.

Conclusions reached to date are based on work completed by G&M in January and April 1995. In two reports prepared at that time, G&M evaluated the aquifer capacity to accept treated effluent without bringing the water table to within 8 feet of the ground surface at the site of a basement or septic system (as located by the Town's GIS system). G&M based their conclusions on a groundwater model that was calibrated to June 1992 groundwater elevations and WPCF flow rate of 1.8 MGD.

The G&M modeling effort concluded that when groundwater was naturally at the highest elevation, the Benchmark Elevation at Nevada Bob's would be exceeded with a plant flow of 1.0 MGD. The evaluation used the Frimpter and Belfit (1992) correction to estimate maximum groundwater elevation. The Frimpter and Belfit correction was developed by the Cape Cod Commission and the USGS to assist the home building industry to determine the possible fluctuation of groundwater elevation to aid in the

design and construction of septic systems. The correction uses historical data from USGS index wells to determine the likely range of groundwater elevations. The historical data covers a range of highest to lowest historical levels. The water level of a well of interest (say well 92-16) is compared to the groundwater elevation of the nearest USGS index well on a date of interest (June 1992). We can determine where the well of concern is in its natural range of fluctuation by measuring the index well's level in its natural range of fluctuation. The G&M report concluded that from the groundwater levels at the time of model calibration, groundwater near the WPCF had the potential to rise 6.4 feet to achieve a maximum high groundwater condition.

Groundwater model runs that simulated various plant discharge rates led G&M to conclude that the Benchmark Elevation (36.26 feet at Nevada Bob's) would be exceeded at a flow rate above 1.0 MGD.

Original Benchmark Elevation calculations were based on the elevation of the former Nevada Bob's basement. The basement is no longer present, and other properties that could be potentially flooded in the Enterprise Road industrial area have been addressed. It therefore became necessary to define the next location most susceptible to flooding due to high groundwater.

The goals of the project were met through the following sequence of tasks:

A. **Determine Benchmark Location.** The properties that would be the first ones to potentially experience flooding (either in basement or first floor) or disrupting the operations of a septic system (if applicable) as groundwater elevations rise were identified.

B. **Determine Benchmark Elevation.** Once the properties were identified, the elevation at which flooding or disruption of the septic system was identified.

C. **Determine WPCF Effluent Discharge Rate at Maximum Groundwater Elevation Conditions.** Based on the G&M groundwater model maps, the maximum month flow rate at the WPCF that results in the Benchmark Elevation being exceeded was determined.

D. **Determine Critical Groundwater Elevation at WPCF.** Using existing mapping data, a critical groundwater elevation at a WPCF well, that would indicate that the Benchmark Elevation is potentially going to be exceeded, was determined.

PRELIMINARY EVALUATIONS

Prior to identifying the Benchmark Location and Elevation and the corresponding WPCF maximum monthly effluent discharge rate, a number of preliminary evaluations were conducted to verify the applicability of the methods and associated assumptions used. Detailed descriptions of the preliminary evaluations are provided as an attachment to this letter and are summarized below.The preliminary evaluations included:

- Confirming the accuracy of Frimpter adjustment – A comparison of actual high groundwater conditions (observed in 1998) to Frimpter predictions, and a statistical analysis of groundwater elevations using available historical data both demonstrated that a Frimpter adjustment to the 1992 water levels of approximately 6 feet was generally met.

- Confirming the accuracy of G&M predictions – G&M model projections were compared to actual groundwater levels at modeled conditions that were met in 2002. The comparison revealed that the predictive capabilities of the model are generally accurate but that the original calibration of the model was approximately one foot high so predicted levels are generally one foot high.

- Evaluating the precision of collected data – This evaluation concluded that the model is generally accurate but that it is not very precise. A number of generalizations and assumptions are inherent in modeling. Although the models are precise enough to be used as a general planning tool, they cannot be considered so precise that they can define a precise "Benchmark Elevation" upon which definitive engineering decisions can be made. Predicted elevations ranged from 0.4 to 2.7 feet above observed levels. Based on this conclusion the benchmark determination was to be conducted using groundwater elevations within a precision of +/- 0.5 feet.

- Completing a sensitivity analysis – This evaluation was completed using a representative number of potentially impacted locations to test various model scenarios including: (1) evaluating data precision and rounding, (2) refining the accuracy of the model by lowering the model predictions by one foot, (3) considering a reduced maximum high water level adjustment and changing depth of when a basement would flood from 8 feet to 7 feet. Based on the sensitivity analysis, a most likely scenario was defined for completing the benchmark identification effort.

After refining the evaluation criteria, as described above, Stearns & Wheler proceeded with a process for identifying the Benchmark Elevation.

IDENTIFICATION OF BENCHMARK ELEVATION AND LOCATION

Following the sensitivity analysis, Stearns & Wheler completed the evaluation by determining which property would be the first to be flooded or whose septic system operation may be disrupted as groundwater elevation increased. The evaluation was completed using the parameters defined in the proceeding section and the G&M modeling results presented in their April 1995 report. To complete the evaluation, the prior results from the 350 foot per day hydraulic conductivity runs were compared. The hydraulic conductivity of 350 feet per day was used because this value was verified by a pumping test completed at the Hyannis WPCF. Potential high groundwater impacts were defined as groundwater either (1) causing flooding, (2) flooding a basement or ground level floor (based on a basement floor being 8 feet below ground surface) or (3) coming within 8 feet

of ground surface at the site of a septic system leaching field (based on Title 5 criteria). Each of the 22 areas identified by the 1995 modeling were evaluated to determine which location would be impacted first as water levels increased as a result of modeled plant flow being added to a condition of maximum high groundwater.

The evaluation is summarized in tabular form on Table 1. The areas evaluated on Table 1 are shown on the attached Figure 1. Figure 1 shows the area in a one-mile radius around the WPCF. The drawing also shows the groundwater elevation contours for the modeled condition of the plant discharging 2.5 MGD during a maximum high groundwater condition. Also shown on the map are the 22 areas where increased groundwater elevation has the potential to exceed the bottom elevation of structures or septic systems as shown in varying shades of blue. Table 1 identifies these susceptible low areas. Each of the 22 areas were evaluated by determining the potential for groundwater to exceed the lowest elevation of a structure or septic system. On Table 1, there are two rows of data associated with each incremental plant flow rate. The upper row indicates resultant groundwater elevation at the indicated flow rate during low groundwater conditions as were observed in June 1992, the model calibration date. The lower row indicates resultant groundwater elevation at the indicated flow rate during a maximum high groundwater condition. The green cells indicate that the parcel would not have structures low enough to be effected at the stated flow rate. The yellow cell indicate if one of the three criteria used in defining impacts occurs at the given flow rate during low groundwater conditions. The orange cells indicate where impact occurs at the given flow rate during maximum high groundwater conditions.

The evaluation indicates that there are seven areas where predicted groundwater elevations exceed elevations that could result in either potential flooding or disrupting the operation of an existing septic system during the discharge of 1.0 MGD or less during maximum high groundwater conditions. These seven areas include:

Area G&M Study Designation	Description	No. of Potentially Impacted Parcels
2	Dunns Pond	20 houses
3	Lincoln & Arrowhead	10 houses
5	St Francis Circle	8 houses
7	Hampshire Avenue	2 houses
9	Crooked Pond	Schoolyard flooding
8	Hambden Circle	28 houses
12	Blanchard Liquors Area	Comm. property flooding

Because of the number of properties, a single benchmark location and elevation is not identified. Based on the model, potential flooding of buildings or disruption of septic system operations at these parcels may occur at a plant flow rate of 1.0 MGD or less during maximum high groundwater conditions.

Following the first Benchmark Location and Elevation Identification task, the task was repeated with a modified definition of when basements may flood or when a septic system's operation may be disrupted. In the second evaluation, the definition of impact included only surface flooding and impact to basements or first floors. Potential impacts to Title 5 compliance were not considered in this evaluation with the justification that the four or five foot separation criteria established by Title 5 is conservative and that short occurrences of groundwater being within that range will not adversely affect the performance of the system. Under this evaluation the number of sites potentially impacted at 1.0 MGD and maximum high groundwater conditions is reduced from seven to three, including Dunn's Pond, a depression at Lincoln and Arrowhead and basements along Route 28 east of the WPCF.

CONCLUSIONS

- This evaluation was originally undertaken to verify certain aspects of the methods used (Frimpter adjustment, model prediction capabilities) and to update the benchmark and plant flow rate identification efforts undertaken previously by the Town. The evaluation demonstrated that the model predicts groundwater elevation reasonably accurately but that it does not necessarily predict where and when impacts occur. The treatment plant has routinely discharged between 0.9 and 2.5 MGD on a monthly basis for a number of years with virtually no documented areas where groundwater has flooded structures or disrupted septic systems being reported. Only in the spring of 1998, when groundwater reached its maximum natural elevation and the plant was discharging from 1.8 to 2.0 MGD, were impacts identified. Some flooding was detected on Corporation Drive and on Route 28 just east of the facility. One basement at St. Francis Circle was reportedly flooded. Since the spring of 1998, the Town has undertaken a number of mitigation efforts. The house at St. Francis Circle was purchased and easements have been obtained from two businesses along Corporation Drive and Route 28. The basement of Nevada Bob's, the original Benchmark Location was filled in by its owner. Other commercial buildings on Enterprise Road have reportedly been demolished or modified. These actions by the Town and others should effectively eliminate the reoccurrence of flooding of structures or disruption to septic systems.

- There are several characteristics of the model that limit its utility to precisely predict when and where flooding of a structure of disruption of septic system operations will occur, therefore effluent management planning decisions can not be made solely on the model results. These limitations include:

  - The evaluation relies on a uniform hydraulic conductivity of 350 feet per day across the entire study area. Although this is a reasonable generalization, it is, in all likelihood, an oversimplification.

  - Although average predictions are generally accurate, the differences in actual from predicted groundwater levels ranged from 0.7 to 2.4 feet. In this evaluation, a one

foot adjustment was applied to the model results, but a residual difference of up to 1.4 must still be considered.

- The Frimpter adjustment of 6.0 was considered representative, but the actual range in groundwater elevation difference between June 1992 (the model calibration date) and May 1998 (a maximum high groundwater condition) ranged from 5.2 to 7.8 feet. Additionally, the Frimpter adjustment varies with distance from the index well and distance from the coastline, meaning that a single average number is not precise.

To summarize, although the model is a representative tool, it cannot be considered so precise that major engineering and planning decisions can reasonably be made on the prediction of potential flooding of structures or disruption to septic systems. Impacts have been defined based on water level fluctuations of no more than a foot or two, but fluctuations of that magnitude are well within the inherent errors in the model.

- The Hyannis WPCF has operated at rates ranging from 0 to 0.9 to approximately 2.5 MGD on a monthly flow basis over the past 15 years. Only once in that time period (spring 1998) was there documented flooding of structures or disruption to septic systems resulting from high groundwater. Actual groundwater level data and the statistical evaluation conducted corroborate the conclusion that maximum high groundwater reoccurs every 20 to 25 years. The infrequency of the potential impacts should be regarded when considering effluent management planning.

RECOMMENDATIONS

Stearns & Wheler recommends that the Town base its effluent management plans on criteria other than a specific defined Benchmark Elevation and the resultant limited flow rate. Specifically, observed historical conditions should be regarded in establishing the Town's effluent management strategies.

Stearns & Wheler recommends that the Town of Barnstable pursue remote discharge sites for monthly flows greater than 2.5 MGD during periods of high groundwater to

accommodate needed additional capacity. As described above, the structures that had flooding in basements in the spring of 1998 have been addressed through demolition, basement filling, direct purchase or acquisition of easements. These actions have reduced the potential for flooding to occur or have eliminated the Town's liability for flooding that might occur at these properties. Given the limitations of the model discussed above, it is not feasible to exactly predict at what discharge rate and at what location additional flooding might occur. The recommended monthly flow rate of 2.5 MGD is an estimate based on an understanding of the mounding and natural groundwater elevation fluctuations and the mitigation efforts taken so far by the Town. If necessary, to accommodate additional flows from: Areas of Concern identified in the WWFP; Chapter 40B Affordable Housing Developments; and infilling with the existing sewer service area, the Town may proceed to add these flows, with the understanding that the risk of property flooding is increased during high groundwater periods. The Town should implement a risk management strategy that would address potential flooding of structures during high groundwater periods when the Hyannis WPCF is discharging flows greater than the current maximum monthly flows. Stearns & Wheler recommends that the Town immediately begin the process of developing remote discharge sites based on an acceptable risk management strategy. The Town could move forward with currently planned sewer extension projects, but should not initiate construction of these extensions until a remote site has been identified to be technically feasible and is available for use by the Town.

The Town should continue its groundwater elevation monitoring program and supplement it with a monthly evaluation of depth to water in potentially impacted areas so that potential impacts can be predicted.

The Town should establish a "Sentinel Well" at the WPCF. Because of the number of properties that could potentially be impacted, identifying a single benchmark location and elevation is not appropriate. Rather than establishing impact at one of these locations as the benchmark, a groundwater elevation of 36.5 at the WPCF, in monitoring well PT-300SE, feet has been determined to correlate to potential impacts at any of these properties. This elevation is presently an approximation based on the well's proximity to one of the modeled areas, Area 22, the lower parking lot at the WPCF. Well PT-300SE

would reflect a similar groundwater elevation as modeled for Area 22. Closer inspection of the area and a determination of the measuring point elevation of well PT-300SE will allow the "Critical Groundwater Elevation" at well PT-300SE to be better defined.

Upon the Town's review and approval and any subsequent revisions, the content of this letter report will be integrated into the Wastewater Facilities Plan. If you have any questions regarding the content of this letter, please call.

Very truly yours,

PROJECT SCOPE – PRELIMINARY EVALUATIONS – SENSITIVITY ANALYSIS

1.0 PROJECT SCOPE

The scope of work for this evaluation, as developed in the contract for services is presented below:

Task No.	Task Description
1.	Compile, review, and interpret existing data related to the Benchmark Elevation Evaluation. This task includes reviewing model calibration and comparing theoretical high groundwater levels with measured high groundwater levels. Additionally, this task will include compiling existing groundwater elevation data maintained by the Water Pollution Control Department (WPCD, and developing groundwater elevation contour maps on two historical dates and comparing actual conditions of water level and Water Pollution Control Facility (WPCF) flow with the modeled results. The purpose of this effort is to further validate the groundwater model upon which the benchmark evaluation is based. Meet with Town to summarize existing status of evaluation.
2.	Request Town GIS Department to create map revisions of 2.5, 2.8 and 4.0 mgd scenarios by changing the Frimpter adjustment to 6.4 feet rather than the 6 foot adjustment used previously. (Note: Groundwater elevation maps exist that show modeled water table contours based on discharge rates of 2.5, 2.8, and 4.0 mgd. Those maps also show potentially impacted parcels if a Frimpter maximum water table elevation factor is considered.) Modifications of those maps are required to continue the Benchmark Elevation Evaluation. Provide direction to GIS Department as to what changes are needed and what the final maps should show. (Revised contours, revised definition of impacted areas).

3. Identify areas where groundwater comes to within 8 feet of the surface using the revised maps and the 2.5 mgd scenario. If impact is observed at 2.5 mgd, evaluation will continue as described in Task No. 4. If no impact is observed at 2.5 mgd, other flows (2.8 and 4.0 mgd) will be evaluated until a flow rate causing impact is identified. Once the flow rate that could potentially cause impact is identified, the impacted parcels will be identified as described below.

4. Request Town GIS Department to determine whether basements or septic systems are present in the potentially impacted areas by reviewing the existing database. If septic systems are the item of concern, the likelihood and effect of sewering will be considered.

5. Identify the first parcel(s) where a basement or septic system could potentially be impacted by a rising water table.

6. Request that the Town survey the potentially impacted parcels to determine actual elevation of parcel and of impacted structure (based on known, assumed or measured depth below grade). Review survey information; determine critical groundwater elevations based on actual surveyed elevations of potentially impacted parcels.

7. Identify the following, based on results of the evaluation:

   a. Potentially impacted parcel(s)
   b. Benchmark Elevation (elevation of groundwater at the potentially impacted parcel at which point impact could occur)
   c. Plant flow rate that results in adverse impact
   d. Maximum allowable discharge from WPCF
   e. Groundwater elevation in a WPCF well that corresponds to off-site impact.

8. Prepare a draft letter report that summarizes the results of our evaluation including maps, tables, and calculations. Following review and comment by the Town, conclusions and recommendations will be integrated into the Facilities Plan.

2.0 PRELIMINARY EVALUATIONS

As part of Task 1, a number of evaluations were performed to check the accuracy of methods and assumptions used in prior benchmark evaluations. The check on accuracy was warranted at this time because several years of groundwater elevation data have been collected since G&M completed their modeling in 1992. The groundwater elevation records were used to characterize the accuracy of the model predictions as well as to verify that the Frimpter Belfit method, which was used to predict potential maximum high groundwater levels, is representative of actual groundwater elevation observations. The existing treatment plant records that were compiled, reviewed, plotted, and interpreted as part of the separate Effluent Mitigation Investigation Task 2, provided the basis for these evaluations. Reviewing this data allowed us to identify the fluctuations in groundwater elevation, observe trends, and draw conclusions related to relationships between groundwater elevation changes, precipitation and WPCF flow rates. Selected exhibits from that review are included with this report as Appendix A.

2.1 COMPLETED EVALUATIONS

A. Evaluation 1 – Confirm Accuracy of Frimpter Adjustment

The first evaluation entailed confirming the accuracy of the Frimpter adjustment that predicts maximum potential high groundwater elevation. Stearns & Wheler completed this evaluation using two methods:

- a comparison of actual high groundwater conditions (observed in 1998) to Frimpter predictions, and

- conducting a statistical analysis of groundwater elevations using available historical data from both WPCD and USGS

The first half of this evaluation was made by comparing actual high groundwater elevations to elevations that would have been predicted by adding the Frimpter-Belfit correction to June 1992 data. Groundwater elevations from June 1992 were those used by G&M to calibrate their groundwater model. Using the methods prescribed by the Frimpter Belfit method and the June 1992 data, G&M determined that the Maximum groundwater elevation would exist at an elevation 6.4 feet higher than the elevation measured in June 1992.

A review of groundwater elevation trends indicates an approximately 20 year high in May of 1998. Figure 1 shows the fluctuations in groundwater levels as recorded in USGS Index Well A1W-230 located near the Barnstable Municipal Airport (Airport). This plot shows the high water level that occurred in 1987 (approximately 20 years before the 1998 occurrence). In Index Well A1W-230, the water level in 1998 is slightly lower than in 1987, however, if index well A1W-247 is also considered, it can be seen that, at that well, the water level in 1998 was slightly higher than in 1987. The data from these two index wells and the data from the WPCD monitoring wells support the conclusion that May 1998 represents a maximum high groundwater condition. To verify the validity of the Frimpter adjustment, water levels in wells in June 1992 were compared to water elevations in wells in May 1998. There were five wells in the vicinity of the WPCF where data is available on both of those dates. The water levels from those two dates are summarized on Table A1. The average difference in water levels between the two dates is 6.04 feet. The range in difference was 5.25 feet to 7.8 feet.

This data supports the Frimpter-Belfit adjustment as an accurate predictor of what could be the maximum high groundwater elevation in the area of the WPCF. As stated above, G&M based their work on a 6.4 foot difference (although the report inexplicably references a 5.5 difference in one table). Because the available data suggests a correction of approximately 6 feet and for reasons related to precision in this evaluation (presented below) the remainder of the evaluation was completed using a Frimpter-Belfit adjustment of 6.0 feet.

The second half of this evaluation included a statistical evaluation of the Frimpter-Belfit adjustment. The water level histories for the USGS Index Wells and the WPCD monitoring wells were evaluated statistically to determine the frequency of the water levels reaching their maximum condition, as would be predicted by the Frimpter Belfit correction. The statistical evaluation culminated in assigning a water level to various return frequencies ranging from 1 year to 100 years. This evaluation is summarized on Table A2. On Table A2, each column represents one of the WPCD monitoring wells or one of the USGS Index wells. The right column indicates return frequencies and the values under each well heading are the groundwater elevations that are achieved at the frequency indicated. The blue colored cells indicate the groundwater elevations seen in May 1998, the likely maximum high groundwater elevation. The green cells represent the 25 year return frequency. The evaluation indicates that the Frimpter-Belfit adjustment roughly correlates to a 25 year high water event this is generally consistent with the observation made in this study that high groundwater events occurred about 20 years apart.

B. Evaluation 2 – Confirm Accuracy of Geraghty & Miller Predictions

The second evaluation entailed an evaluation of the accuracy of the predictions of the G&M model. This evaluation could not be made at the time the model was developed, because there was no future data to which the model predictions could be compared. The model had been calibrated to a single point in time, June 1992. The accuracy of its predictions could not be evaluated until future data was accumulated. There is approximately 10 years of data available since the model was calibrated.

To complete this evaluation Stearns & Wheler compared a predicted scenario of the model (WPCF flow of 2.5 mgd during a low groundwater period comparable to that present when the model was calibrated in 1992.) That situation was found to exist in July 2002. In July 2002, background groundwater elevations were comparable to those in June 1992. Also in June 2002 the WPCF was operating at a rate of approximately 2.5 mgd, a condition predicted by the model.

Table A3 compares modeled groundwater elevations for a low groundwater-2.5 mgd condition to actual low groundwater-2.5 mgd conditions experienced in July 2002. On this table the third column represents the difference between the modeled water level and the measured water level. The difference ranged from plus 0.7 feet to 1.78 feet. The average difference was 1.21 feet. In accordance with the conclusions reached while evaluating the precision of the data in the study (as discussed in the next evaluation) the difference between actual and modeled conditions is rounded to 1.0 feet. The one foot difference is not attributed to the model not predicting accurately but is attributed to the fact that the model was one foot high when calibrated. The actual predictive capabilities of the model are quite accurate when that one foot correction is considered. Based on this evaluation and a review of the G&M process and mapping in general, Stearns & Wheler concluded that the G&M results are consistently, approximately 1 foot high. It was acknowledged by G&M in their original report that their calibration was completed with modeled groundwater elevation approximately 1 foot above the measured levels at the time of calibration. G&M proceeded with their modeling at this point and indicated that the 1 foot difference would make their predictions conservative, building in a margin of safety. Our benchmark evaluation proceeded incorporating a 1 foot adjustment to the modeled results obtained by G&M.

C. Evaluation 3 –Precision of Evaluation data

The third evaluation entailed looking at the precision of data. Historically the benchmark evaluation had been conducted looking at water levels within 0.01 feet to make decisions. A look at the origins of the data and the assumptions that were necessary indicated that the evaluation should not rely on data any more accurate than +/- 0.5 feet. This generalization was made after considering the following:

- The Frimpter-Belfit adjustment varies with distance from the coast. Although the method establishes broad areas where a single adjustment is prescribed, in reality the adjustment varies across those areas.

- The modeling is based on a constant hydraulic conductivity of 350 feet per day. This number is only an estimate and would vary across the model area.

- The model results can only be considered to be estimates given the inherent assumptions used in the modeling process. The precision of the model itself cannot be considered to be any more accurate that plus or minus 0.5 feet.

- There is some variability in elevation data. When comparing well elevations to surface elevation data derived from either MassGIS or Barnstable GIS, there is not always a match. In some cases the differences are several feet.

For all of these reasons, the evaluation proceeded using the premise that all predictions of groundwater elevations could be considered to be accurate within the range of plus or minus 0.5 feet.

D. **Summary**

The three preliminary evaluations culminated in the following conclusions:

- The Frimpter-Belfit adjustment of approximately 6 feet accurately predicts the potential maximum high groundwater elevation that might occur, based on June 1992 groundwater levels. *A Frimpter-Belfit adjustment of 6 feet is appropriate and was added to modeled June 1992 groundwater elevations to predict the maximum, natural, high groundwater elevation in the study area.*

- The model generally predicts groundwater elevations that are one foot higher than measured groundwater elevations. This is attributed to the fact that the model was considered calibrated when it matched measured groundwater elevations of June 1992 to within approximately one foot, being approximately one foot higher than measured values. This differential was accepted by G&M as a built in degree of conservatism. Other than this initial calibration difference, the model predicts future conditions with

an acceptable degree of accuracy. *This evaluation will incorporate the consistent one foot differential into future evaluations; that is, predictions of water elevations made in this investigation were determined to be one foot lower than the G&M model result.*

- Given the many inherent inaccuracies in modeling, application of the Frimpter-Belfit adjustment and in assigning a single hydraulic conductivity value over a large area and a thick vertical section of the aquifer, a reasonable level of precision must be used in this evaluation. *A degree of precision of plus or minus 0.5 feet is appropriate and was applied the interpretations.*

3.0 EVALUATION METHOD SENSITIVITY ANALYSIS

After refining the evaluation criteria, as described above, Stearns & Wheler proceeded with a process for identifying the Benchmark Elevation. The procedure identified the groundwater elevation at the parcel where rising groundwater would cause impact. The same methods were employed that were used in earlier iterations of the Benchmark Evaluation, that is, the results of the G&M model, coupled with the adjustments in procedure identified in the previous section were used to identify where impacts might occur.

To complete this evaluation, a number of sensitivity analysis runs were completed at a select number of likely locations to see first impact. These locations included Alicia Road (Area #4), St. Francis Circle (Area #5), Branchard Liquors (Area 12) and Corporation Drive (Area 13). In the sensitivity analysis Stearns & Wheler adjusted the following parameters to determine the extent to which the results were impacted. A change in results means that impact at a particular location, as determined by the modeling, would occur at a different flow rate at the WPCF than first concluded in the 1995 evaluation.

A. Run 1 - Baseline Run

This interpretation used the G&M data exactly as presented in their 1995 report. This run served as a basis of comparison for the other runs of the sensitivity analysis. This run allowed the

determination of a WPCF flow that resulted in impact as defined in this investigation.

B. **Run 2 - Change Accuracy to +/- 0.5 Feet**

All values used in the evaluation, including depth where impact could occur and model projections were rounded to the nearest one-half foot. This change had no impact on the results for the sites being evaluated in the sensitivity analysis.

C. **Run 3 - Lower Model Results of Water Table Elevation by One Foot**

In this run, the elevation of the modeled water table was lowered one foot based in the conclusion stated above the G&M model appeared to be approximately one foot high. This change increased allowable flow from 1 mgd to 1.5 mgd before impacts occurred at St Francis Circle.

D. **Run 4 - Change Depth of Impact From 8 Feet Below Ground Surface to 7 Feet Below Ground Surface (in combination with Run 3 adjustment)**

Because the definition of impact occurring at 8 feet is a policy decision by the Town, it is possible to vary this parameter to evaluate the affects of changing it. With this change, impact at St Francis Circle occurred at an increased flow rate 2 mgd. Hampshire Ave impact occurred at a flow rate that increased from 1 mgd to 1.5 mgd.

E. **Run 5 - Change Maximum High Groundwater Adjustment (Frimpter-Belfit Adjustment) From 6 Feet to 5 Feet. (In Combination with Run 3 and Run 4 Adjustments)**

This change was based on the decision that wastewater management would not be restricted by the maximum groundwater elevation but by a more frequently occurring, but lower groundwater condition. In this run St. Francis circle impact occurred at an increased flow rate of 3 mgd, Hampshire Ave impact occurred at an increased flow rate of 2 mgd.

The results of the five sensitivity analysis runs are summarized on Table A4 and suggests that:

- Rounding the values did not change the results in these particular analyses. However, the final evaluation will be conducted using the rounded number because they are more technically defensible than using water level information accurate to 0.01 feet as was done historically.

- Lowering the water table elevations predicted by the model adds approximately 0.5 mgd to the plant flow limit before impact occurs.

- Changing the depth of impact from 8 feet to 7 feet adds approximately 0.5 mgd to the plant flow limit before impact occurs.

- Using a high groundwater level that is one foot lower than predicted by the Frimpter-Belfit method adds approximately 0.5 mgd to the plant flow limit before impact occurs.

Based on the sensitivity analysis, a most likely set of the sensitivity analysis parameters for completing the evaluation was identified. These included:

- All analysis values would be rounded to the nearest half foot

- A Frimpter-Belfit adjustment of 6 feet was applied to June 1992 groundwater elevations to define maximum high groundwater.

- Impact was defined to occur as surface flooding or reaching a depth of 8 feet below grade where either basements or septic systems are present.

RE: Wastewater Implementation Committee – Grant Project
Draft Report – Effluent Disposal and Reuse Planning:
Guidance Document and Case Study Report
Stearns & Wheler Job No. 40198.0

Dear Mr. Giordano:

Enclosed please find fifteen copies of the Draft Report: Effluent Disposal and Reuse Planning: Guidance Document and Case Study Report. The submittal of this draft document constitutes completion of Tasks 1-5 as described in the Town's Memorandum of Agreement with Barnstable County and the Town's Agreement with Stearns & Wheler. The copies of the draft report are provided for review by the Town and the Wastewater Implementation Committee.

If you have any questions regarding this submittal, please call.

Very truly yours,

STEARNS & WHELER

PART 1 - IDENTIFICATION AND CHARACTERIZATION

SECTION 1 - INTRODUCTION

1.1 BACKGROUND

This document has been prepared to assist communities in Cape Cod, coastal Massachusetts, and other coastal communities with similar wastewater management concerns, to identify land-based wastewater disposal technologies that are cost effective and protective of the environment. The procedures presented in this document are an integral part of wastewater management planning efforts on Cape Cod and elsewhere.

Cape Cod is an area that has experienced significant population growth in recent decades. The area is also home to a number of sensitive ocean, estuarine, and freshwater ecosystems. A consequence of the increasing population is the impact to the environment as a result of wastewater discharge. For approximately two decades, communities on Cape Cod have been studying their wastewater management programs in a comprehensive manner to evaluate existing practices, potential impacts of those practices, future needs, and potential solutions to mitigate these impacts. Through the years, the Massachusetts Department of Environmental Protection (MADEP) has worked to formalize the evaluation process. In January 1996, MADEP issued the *Guide to Comprehensive Waste Water Management Planning*, which described the multi-phase procedure for completing wastewater planning efforts. In March 2002, MADEP drafted an update to the 1996 document and titled it *Guide to Integrated Water Resource Management Planning*. This updated document recognizes the connection that modern wastewater management has with the management and protection of all water resources. The guidance document has not yet been finalized, but is expected to be released in the near future.

More recently, one of the most significant developments in the wastewater planning process was the inception of the Massachusetts Estuaries Project (MEP). Nutrient enrichment of estuaries along the Massachusetts coastline has become the greatest consequence of wastewater discharge. Elevated levels of nutrients (nitrogen, in particular) are adversely impacting recreational opportunities, shellfish and sea grass habitats, and breeding grounds for marine fisheries (see Figure 1).

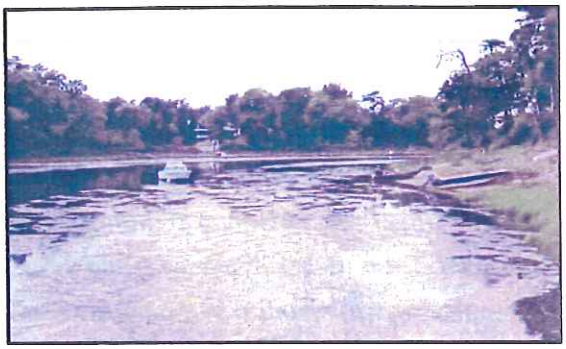

Figure 1 - Some coastal waters have become choked with weeds as a result of nutrient loading.

The MEP is a collaborative effort among coastal communities, MADEP, the University of Massachusetts in Dartmouth, the U.S. Geological Survey (USGS), the Cape Cod Commission (CCC), School for Marine Science and Technology (SMAST), the U.S. Environmental Protection Agency (USEPA), and the Executive Office of Environmental Affairs. The objective of the program is to develop total maximum daily load values for watershed nitrogen loadings to the estuaries. The program entails detailed evaluations of watershed areas, nitrogen loading from all nitrogen sources, tidal flushing rates, and water quality modeling to establish the nitrogen limits. This program is having a significant impact on comprehensive wastewater management planning on Cape Cod and has prompted communities to proactively advance their planning efforts (see Figure 2).

Figure 2 - Estuaries on the Cape Cod coast. The Three Bays area in the Town of Barnstable.

An integral aspect of wastewater management planning is the disposal of treated wastewater. As more towns evaluate their options, centralized treatment plants are being upgraded, expanded, or constructed. In each case, facilities for treated wastewater disposal are required.

Cape Cod and all of coastal Massachusetts is under the jurisdiction of the Ocean Sanctuaries Act, which, by prohibiting "activities that may significantly alter or endanger the ecology or appearance of the ocean, seabed or subsoil of sanctuaries," effectively eliminates ocean outfalls as a viable alternative for disposal of treated wastewater. As a result, Cape Cod

communities must rely on some form of land disposal for treated wastewater.

Another symptom of a growing population is the increased demand on water supplies. Public water suppliers have had to be more aware of groundwater levels in times of drought and high use. Seasonal shortages, coupled with the concept of deriving beneficial uses from treated municipal or industrial wastewater, have prompted the emergence of wastewater reclamation, recycling, and reuse as an integral component of water resource planning, even in the historically water-rich Northeast. As such, beneficial reuse of treated wastewater has become a major consideration related to wastewater management on Cape Cod.

1.2 PURPOSE OF DOCUMENT

Land disposal of treated wastewater represents many challenges for communities. In seeking locations for land disposal, communities must consider the following:

- Is there sufficient land available?
- Will the soil and groundwater conditions at the available land be suitable?
- Are there sensitive ecological systems in the vicinity of the available land that could be impacted by discharge?
- Is wastewater disposal a land use that is consistent with the surrounding land use?
- Is the available land close enough to the treatment plant to minimize transmission costs and address issues of bacterial regrowth in the transmission system?
- What disposal technology is the most appropriate?
- Is there a viable reuse component to our wastewater management planning?

The objective of this document is to assist communities in completing the process of finding suitable land for discharging treated wastewater and to determine which of the many disposal technologies best meet the community's needs. This document presents a procedure for identifying and characterizing candidate sites and provides guidance in selecting appropriate discharge technologies.

In addition to providing a description of general procedures, this document will also provide a Case History of the process employed by the Town of Barnstable, MA (Town) during their Comprehensive

Wastewater Management Planning project (CWMP) to identify candidate disposal sites. The Town has been involved in CWMP for a number of years. The planning process has resulted in a number of improvements to the existing wastewater treatment plant, construction of sewers, and plans for additional sewers. Although the Town has significant capacity for disposal at the existing treatment plant, plans for future expansion of the plant have led the Town to identify new, remote sites for additional capacity. The Town's application of the general procedures described in Part I of this document are presented in Part 2.

This document focuses on environmental conditions and wastewater management concerns found on Cape Cod. However, the procedures and technologies presented herein are applicable to communities across Massachusetts as well as in other states, especially coastal communities.

SECTION 2 - AVAILABLE DISCHARGE TECHNOLOGIES

2.1 INTRODUCTION

There are a number of technologies available for land disposal or recharge for beneficial reuse of treated wastewater. Some of these technologies are commonly used on Cape Cod and in the region. Others are used in other regions of the United States, but have little or no history of use in this area. And finally, some can be considered innovative technologies.

The most common means of treated wastewater disposal in the area, especially for larger municipal treatment plants, is rapid infiltration beds (RIBs). This disposal technology utilizes open sand beds into which treated wastewater is discharged. The treated water infiltrates through the sand, into the subsurface soils, and ultimately into the groundwater.

The second most used technology is subsurface infiltration. These systems are typically used for smaller municipal treatment plants or for smaller package plants for neighborhoods, institutions, or commercial facilities. Leaching of treated wastewater is accomplished through the use of subsurface chambers, pits, or trenches.

Spray irrigation is a common land disposal alternative in southern climates, but because its effectiveness is limited in areas where freezing occurs, it is not frequently

used in a northern climate. Cape Cod has two spray irrigation installations.

Drip irrigation is another proven technology for wastewater disposal with a beneficial reuse component; however, no drip systems are known of in the area.

Injection wells are utilized primarily in Florida and southern California to accomplish both disposal and beneficial reuse. The use of injection wells, although a proven technology in those regions, is regarded as an innovative technology in the Northeast.

Wick wells are modified injection wells that rely on gravity flow rather than pumping water under pressure. There are currently two wick well installations in the southeastern Massachusetts region.

Wetland restoration is another innovative disposal/wastewater management method being considered. This technology/ management concept utilizes effluent recharge upgradient of a previously disturbed wetland (such as abandoned cranberry bogs). It also includes the restoration of the wetland to produce a more varied and natural wetland setting that can assist with natural nitrogen attenuation in the wetland. There are several wetland restorations currently being considered on Cape Cod.

Each of the technologies introduced above will be discussed in greater detail in the following section in terms of operating principle, design considerations, and suitability in given conditions. A consolidated summary of these technologies is presented in Table 2-1.

2.2 Technology Evaluation

A. **Rapid Infiltration Beds.** RIBs are open basins designed to allow treated effluent to flow across the bottom of the basin and percolate through the sand bed, through the unsaturated zone, and then to the groundwater (see Figure 3).

TABLE 2-1

SUMMARY OF EFFLUENT DISCHARGE TECHNOLOGIES
Effluent Discharge and Reuse
Guidance Document and Case Study Project
Barnstable County Wastewater Implementation Committee and Town of Barnstable, MA

ALTERNATIVE	REGULATORY REQUIREMENTS	EFFLUENT QUALITY	MAINTENANCE REQUIREMENTS AND COMPLEXITY OF OPERATION	FLEXIBILITY	ENERGY USE
Rapid Infiltration Beds	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Effluent is already treated and sand beds provide some additional treatment.	Effluent discharge is reliable throughout the year and easy to maintain.	Flexibility is possible with multiple beds.	Lowest energy requirements due to no need to repump the effluent at the sand beds.
Subsurface Infiltration	Disinfection is not required prior to discharge, unless required to meet the Interim Guidelines for Reclaimed Water Use.	Effluent is already treated and infiltration facilities provide additional treatment. Effluent should be filtered before discharge.	Repair of the beds would be difficult because they are subsurface	Moderate depending on construction of dosing equipment and distribution piping.	Moderate due to effluent dosing pumps.
Spray Irrigation	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Spray irrigation provides further uptake of nitrogen in the effluent.	Moderate maintenance to maintain piping. Spray irrigation cannot be used in freezing weather.	Must have redundant back-up facilities for winter discharge.	Moderate due to repumping requirements.
Ocean Outfall	The Massachusetts Ocean Sanctuaries Act prohibits discharge of municipal wastewater into an ocean sanctuary. An NPDES permit required.	Disinfection may be required for the outfall.	Maintenance similar to a large force main	Minimal, unless land disposal remains for some backup discharge.	Moderate due to pumping requirements
Deep Well Injection	Permitting and monitoring of effluent discharges and design requirements. MADEP is not supportive of this technology.	Effluent must be well treated (filtered and chlorinated) before discharge.	Uncertain reliability due to few operating installations and increased maintenance due to the potential of plugging of injection point with solids.	Installation of multiple wells would allow individual wells to rest or be repaired.	Moderate due to repumping requirements.

TABLE 2-1 (continued)

ALTERNATIVE	REGULATORY REQUIREMENTS	EFFLUENT QUALITY	MAINTENANCE REQUIREMENTS AND COMPLEXITY OF OPERATION	FLEXIBILITY	ENERGY USE
Wick Wells	Permitting and monitoring of effluent discharges and design requirements. MADEP regards this as an innovative technology.	Effluent must be well treated (filtered and chlorinated) before discharge.	Uncertain reliability due to few operating installations and increased maintenance due to the potential of plugging of injection point with solids.	Installation of multiple wells would allow individual wells to rest or be repaired.	Moderate due to repumping requirements.
Wetland Restoration	Possible extensive wetland permitting depending on the type of restoration. Permitting and monitoring of effluent discharges and design requirements. MADEP regards this as an innovative technology.	Effluent must be well treated (phosphorus removal in addition to standard nitrogen removal, and disinfected before discharge)	Very low maintenance requirements and low operations complexity.	Minimal operations control. Flexibility would be provided with variable surface water level controls in the abandoned bog.	Moderate due to repumping requirements.

ALTERNATIVE	LAND REQUIREMENTS	POTENTIAL FOR AIR EMISSIONS	PUBLIC ACCEPTANCE	RELATIVE CAPITAL COSTS	RELATIVE O&M COSTS	SELECTED FOR DETAILED EVALUATION
Rapid Infiltration Beds	Moderate at large wastewater flows when compared to subsurface leaching.	Effluent is treated to a high level and odors would be minimal.	Potential for low acceptance from residents who are impacted by bed siting and construction.	Relatively low due low land area and easier construction.	Low due to low energy requirements and minimal maintenance.	Yes; the technology is simple and reliable. O&M requirements are minimal.
Subsurface Infiltration	Relatively high. Land surface above the infiltration system can be used for other purposes	Minimal.	Acceptance should be high due to minimal visual impacts and potential reuse of land area.	Relatively high due to highest land area and extensive piping.	High due to pumping requirements and potential high repair/cleaning costs.	Yes; technology is reliable and provides secondary use of discharge area.

TABLE 2-1 (continued)

ALTERNATIVE	LAND REQUIREMENTS	POTENTIAL FOR AIR EMISSIONS	PUBLIC ACCEPTANCE	RELATIVE CAPITAL COSTS	RELATIVE O&M COSTS	SELECTED FOR DETAILED EVALUATION
Spray Irrigation	Relatively high. Land above system can be can be used for other purposes when spray irrigation is turned off.	Minimal.	The public will want to see recycling of the effluent though they may be concerned about possible health threats.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to maintenance and pumping requirements.	Yes; it provides additional nitrogen uptake and reuse of the effluent.
Ocean Outfall	Minimal.	Minimal.	Low. Based on the opposition to the Deer Island outfall and the Ocean Sanctuaries Act.	Relatively high due to land area, extensive permitting pumping requirements.	Moderate due to pumping requirements	Yes, as a last alternative if all other land disposal alternatives are not sufficient to meet the Town's need.
Deep Well Injection	Relatively low compared to sand infiltration beds and subsurface leaching.	Minimal.	Land area requirements and visual impacts are minimal.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	No; MADEP is resistant to support the technology due to the need to chlorinate the effluent
Wick Wells	Relatively low compared to sand infiltration beds and subsurface leaching.	Minimal.	Land area requirements and visual impacts are minimal.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	Yes, MADEP has recently permitted a wick facility. Low land area is a benefit, however, MADEP is currently requiring 100% capacity reserve area for conventional system.
Wetland Restoration	Would make use of an existing extensive land area. The restoration efforts would occur in specific flow control and infiltration areas.	Minimal.	Could be favorable due to understanding that the technology/ concept is a restoration effort and the project could restore proper hydraulic balance to the watershed.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	Yes. There is much interest at MADEP with this concept to take an integrated approach to watershed management. This could be cost effective and provide secondary benefits.

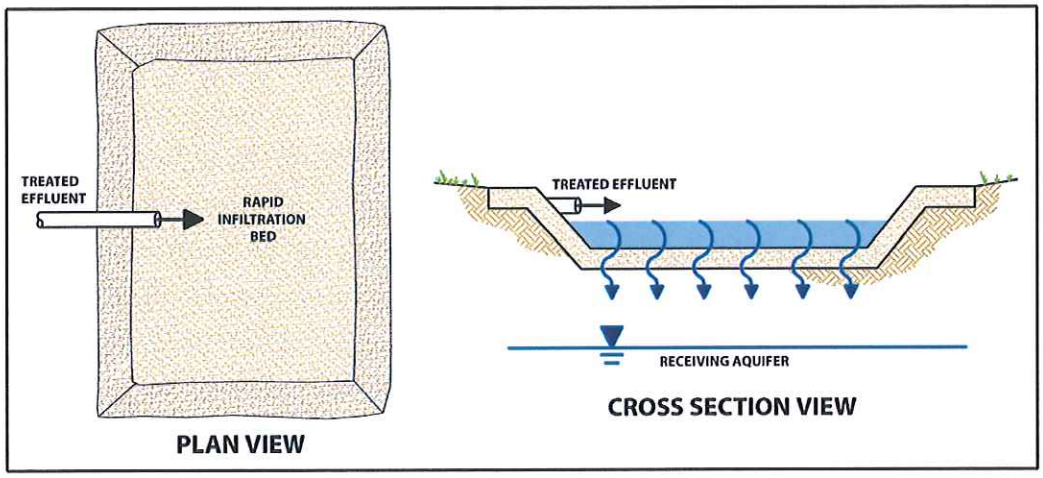

Figure 3 - Schematic of rapid infiltration beds

Bed maintenance is relatively easy because the bed is exposed at the surface and the sand surface can be raked or replaced if the sand becomes plugged with effluent solids. MADEP specifies loading rates for sand beds based on hydraulic conductivity rates of the underlying soils. Loading rates ranging from 2 to 5 gallons per day per square foot (gpd/sq ft) of sand area are suggested for percolation rates that range from 10 to 20 minutes per inch to less than 5 minutes per inch. Cape Cod towns currently utilizing sand infiltration beds as part of their wastewater treatment and discharge facilities include Barnstable, Falmouth, Chatham, and Orleans (Tri-Town) (see Figure 4).

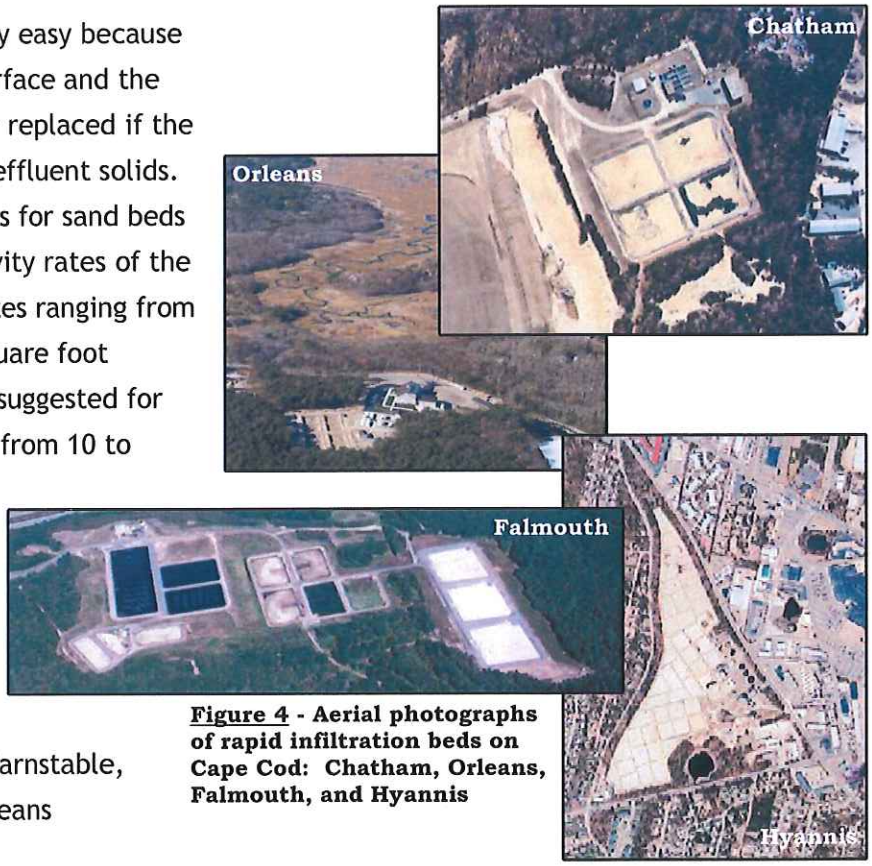

Figure 4 - Aerial photographs of rapid infiltration beds on Cape Cod: Chatham, Orleans, Falmouth, and Hyannis

Effluent disposal in rapid infiltration beds has the following advantages:

- Bed construction is relatively simple (however, it can be complicated by unfavorable subsurface conditions such as presence of boulders)
- Operation and maintenance (O&M) is relatively easy and O&M costs are lowest.
- Hydraulic loading rates are typically higher than other disposal methods, which allow the beds to take up less area.

Effluent disposal in rapid infiltration beds has the following disadvantages:

- Construction of new beds requires the clearing of large areas of land, which may have a visual impact.
- Infiltration beds do not have secondary uses, such as parking lots and recreational areas (as subsurface leaching or spray irrigation facilities might have).
- Low public acceptance.
- Disinfection is typically required.

Although infiltration beds have advantages with respect to cost of construction and ease of O&M, the most significant disadvantage is the area required. A facility with a 1 million gallon per day (mgd) discharge could require approximately 10 acres (see Figure 5) based on current MADEP recommended design criteria (*Guidelines for the Design, Construction, Operation and Maintenance of Small Sewage Treatment Facilities with Land Disposal*, MADEP, 1988).

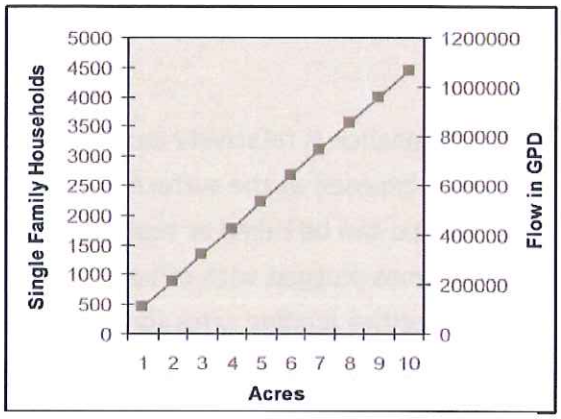

Figure 5 - Land area requirements for rapid infiltration beds

The following must be considered when determining the land area required for RIBs:

- Sufficient area to accommodate the required flow at 5 gpd/sq ft loading rate.
- Approximately 25 to 50 percent additional capacity to allow flow to be rotated between at least two to three

beds to allow beds to "rest" (i.e., dry out or be serviced).

- Approximately 20 percent additional area for berms and service roads between beds.
- A buffer of approximately 50 to 100 feet wide around the boundaries of the site, depending on the surrounding land use.
- A reserve area of approximately 50 percent total site capacity that is set aside and available, but not necessarily constructed, if the original site loses capacity or needs to be repaired over time.

These requirements are open to some degree of interpretation and negotiation with MADEP during the planning and permitting process and depend on the discharge site specifics.

B. **Subsurface Infiltration.** Large-scale subsurface infiltration facilities typically utilize pump and piping systems to pressure dose infiltration areas (trenches, beds, or galleries) where the effluent percolates to the groundwater (see Figure 6).

Maintenance and cleaning of these systems is more difficult because the infiltration area is not exposed to the surface and effluent solids that may accumulate cannot be easily removed. Subsurface infiltration beds can have secondary uses, such as parking lots, lawns, playing fields, and recreational areas. Hydraulic loading rates of 2.5 gpd/sf (of the trench or gallery base and side walls) are typical. Towns currently utilizing subsurface systems include Oak Bluffs and Provincetown (see Figure 7).

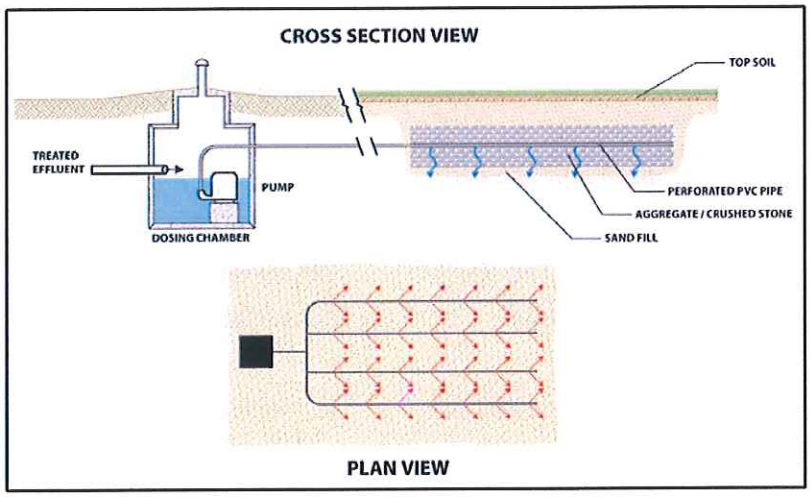

Figure 6 - Schematic of subsurface infiltration system

Figure 7 - Surface at site of Provincetown, MA subsurface infiltration system

Subsurface infiltration facilities have the following advantages:

- Disinfection is typically not required prior to discharge unless it is in a water supply recharge area or upgradient of a sensitive resource.
- Facilities are contained underground and can have a secondary use, such as parking lots and recreational areas.
- High public acceptance.

They have the following disadvantages:

- Large land areas may be required (larger than RIBs) due to lower hydraulic application rates.
- Pressure dosing is typically required for large systems, which increases capital and O&M costs.
- Extensive site work may be required for construction, particularly if the site is forested or there are adverse subsurface conditions
- Due to the limited access for cleaning and maintenance, the facilities may have to be reconstructed if they lose infiltration capacity.

A facility for a 1 mgd discharge could require as much as 18 acres based on current MADEP recommended design criteria (see Figure 8).

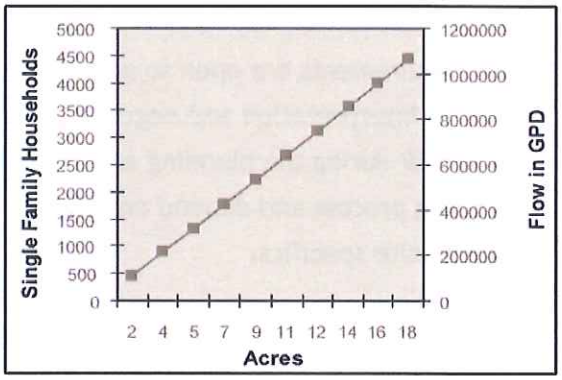

Figure 8 - Land area requirements for subsurface infiltration trench system

The following must be considered when determining the land area required for subsurface infiltration:

- Including a safety factor in the design by designing for 125 percent of the flow (as recently permitted in Provincetown).

- A layout that accommodates 100 percent reserve capacity by leaving space for replacement trenches between the constructed trenches. Trenches must be spaced a distance of three times the trench width (a Title 5 requirement that is considered applicable to larger leaching systems).
- Limit laterals to 100 feet in length (a Title 5 requirement that is considered applicable to larger leaching systems).
- A buffer approximately 50 feet wide around the boundaries of the site, depending on the surrounding land use.

Similar to the sizing requirements for RIBs, the sizing requirements for subsurface infiltration facilities are open to some degree of interpretation and negotiation with MADEP and depend on the discharge site specifics.

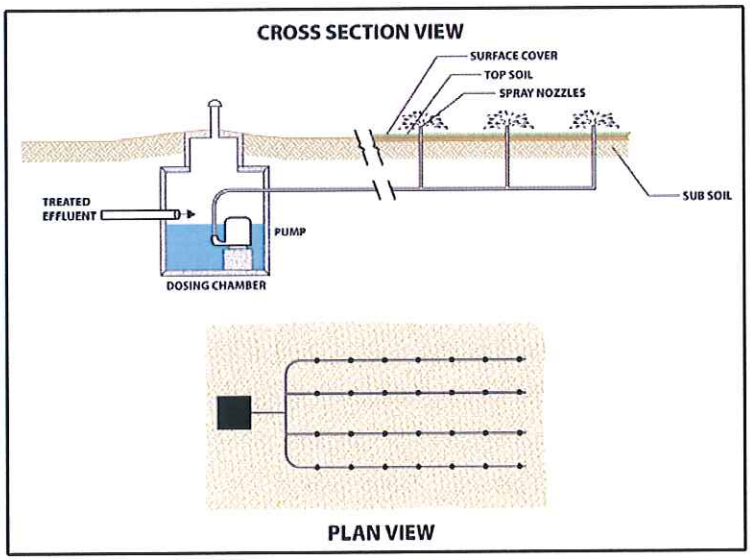

Figure 9 - Schematic of spray irrigation system

C. **Spray Irrigation.** Spray irrigation facilities are typically comprised of effluent pumps, distribution piping, and a spraying system consisting of risers and spray nozzles (see Figure 9). Treated effluent is pumped through various distribution lines and discharged via spray nozzles to the surrounding area. Spray irrigation systems have often been used at golf courses and in large remote fields. Application rates for non-golf course areas are typically 2 inches per acre per week. Application rates for golf courses are typically based on turf management needs. Spray irrigation is currently utilized at a golf course in Yarmouth and at the municipal treatment facility in Falmouth.

The goal of spray irrigation systems is to apply water at a rate that allows the site vegetation to uptake the nitrogen in the water at a rate that will limit the leaching of nitrogen into the groundwater. In some regulatory environments, the nitrogen

uptake capacity of the discharge site vegetation can be the limiting factor in loading rates (see Figure 10).

Figure 10 - Spray irrigation system in use at a golf course

Effluent disposal using spray irrigation has the following advantages:

- Allows for secondary use of land (i.e., golf courses) as regulated by MADEP.
- Provides an inexpensive means of irrigation, reducing clean water demands.
- Provides nitrogen uptake by plant life and also reduced nitrogen application at golf courses.

Effluent disposal using spray irrigation has the following disadvantages:

- Limited cold weather use due to potential freezing problems.
- Spray nozzles may be subject to clogging.
- Requires secondary means of effluent disposal or storage during wet periods, times when the land is being otherwise used (such as golf) and winter months.
- Must meet more stringent MADEP requirements for reclaimed water use, including disinfection.
- Often has low public acceptance due to health risk concerns associated with exposure to pathogens in the effluent.
- Large areas are needed.

A facility for a 1 mgd discharge could require as much as 130 acres, based on a loading rate of 2 inches per week as suggested above (see Figure 11).

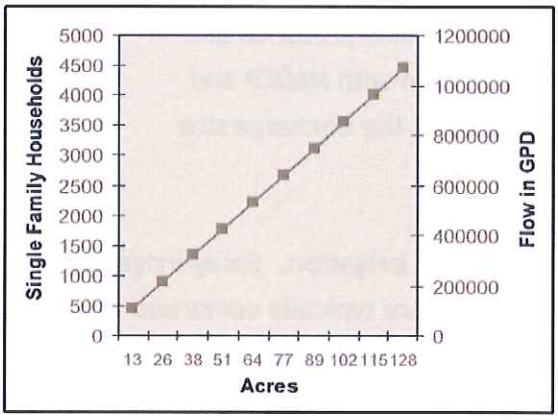

Figure 11 - Land area requirements for a spray irrigation system

D. **Drip Irrigation.** Drip irrigation is a subsurface version of spray irrigation. Treated wastewater is used to irrigate agricultural land (see Figure 12). Subsurface piping is laid out approximately 6 to 12 inches below the surface in areas to be irrigated. Discharge of wastewater is through emitters spaced 12 to 24 inches apart and laterals spaced at 12- to 24-inch intervals. Water is pumped through the lines under pressure but is discharged slowly through the emitters. The intent of the system is to discharge the water into the root zones of the plants, where the nutrients can be utilized by the plants and where increased evapotranspiration may be facilitated.

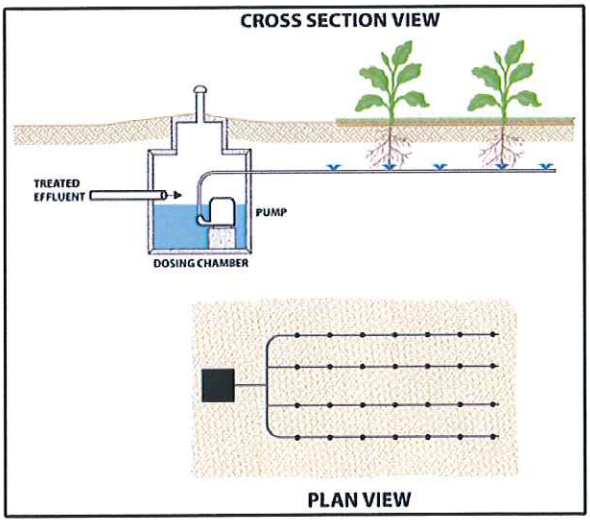

Figure 12 - Schematic of a drip irrigation system

Advantages include:

- Can be used in adverse terrain conditions.
- Is associated with water reuse because water is discharged into root zone of plants or crops.
- Ease of construction.
- Low human exposure to wastewater.
- Low delivery rate to minimize water table impacts.
- High public acceptance.

Disadvantages include:

- Effluent must be highly treated to minimize plugging.
- Difficult to monitor emitter performance.
- Periodic backflushing is required.
- May not operate in very cold conditions.
- Piping must be protected from heavy loads, such as car and truck traffic on the site.

If a system is designed to operate at 0.5 gallons per hour (gph) per emitter, and emitters and lines are at 2-foot spacing, a 1 mgd facility, including 20 percent redundant area, would require approximately 11 acres of land (see Figure 13).

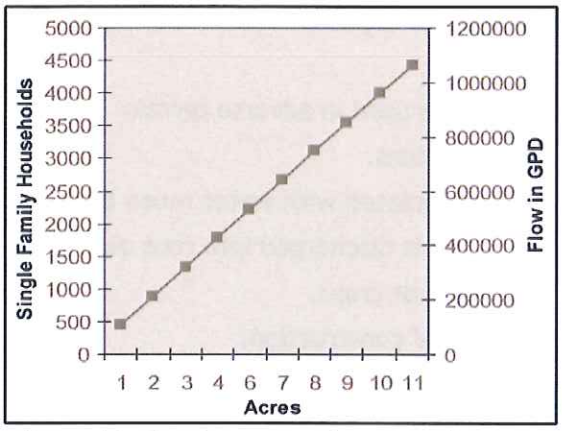

Figure 13 - Land area requirements for a drip irrigation system

treated wastewater has been practiced in Florida for 25 years. There are currently, approximately 47 injection wells in southern Florida. Wastewater injection in Florida differs from wastewater injection envisioned on Cape Cod because injection in Florida is typically at a depth of approximately 3,000 feet, whereas on Cape Cod, the objective of using well injection is to recharge the groundwater system. Therefore, shallow injection into the aquifer would be the likely approach.

E. **Well Injection.** Well injection involves the discharge of treated effluent to groundwater below the land surface. The discharge is accomplished by pumping the effluent through wells that extend into permeable, saturated geologic strata. This type of discharge can be compared to the reverse of extracting water from a well (see Figure 14).

Injection of treated wastewater occurs primarily in Florida and California. Deep well injection of

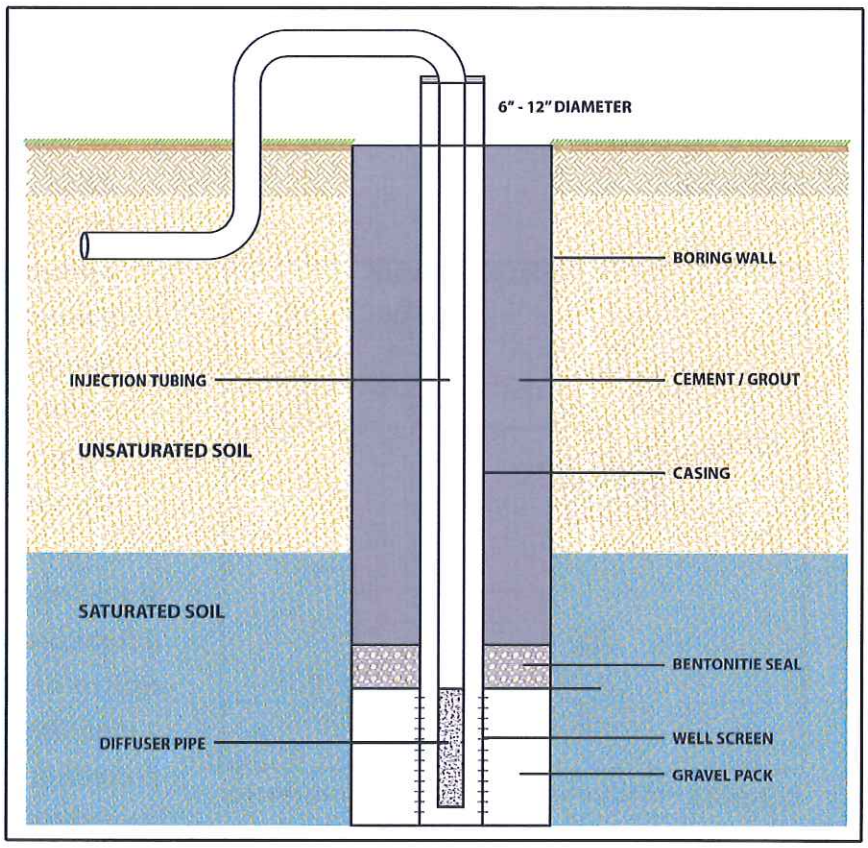

Figure 14 - Schematic of an injection well

In California, excessive pumping of groundwater resources has resulted in a lowering of the water table in coastal areas and subsequent saltwater intrusion. In a project referred to as Water Factory 21, approximately 22.6 mgd is injected into the ground. The California project injects the treated effluent into an aquifer utilized as a water source.

In 1999, the Town of Barnstable conducted an injection well pilot test. Treated effluent and potable water flows of 70,000 to 200,000 gpd, were injected into a 10-inch, 30-foot deep well. The well experienced plugging that was attributed to biological growth in the sand pack or at the boring wall. The test concluded that chlorine disinfection and effluent filtration would be required for injection to be technically viable. MADEP presently prohibits chlorination of injected wastewater due to concerns related to the formation of disinfection byproducts; therefore, injection wells have not been pursued further at this time. MADEP has indicated that as more municipalities seek innovative disposal technologies, the issue may be revisited.

Effluent disposal with well injection has the following advantages:

- Lowest land area requirements.
- Discharge is below grade so visual and odor impacts are low.
- Discharge points (wells) could be spread over a large area to minimize groundwater mounding.

It has the following disadvantages:

- Effluent filtration is needed to provide a high level of nutrient and solids removal to minimize plugging in the wells.
- Relatively unproven technology in Massachusetts, with recent testing at the Hyannis WPCF.
- Chlorination is needed, which conflicts with guidance from MADEP.

E. **Ocean Outfall.** This alternative would involve the siting, construction, and operation of an ocean outfall for effluent disposal into the Atlantic Ocean, Cape Cod Bay, or Nantucket Sound. Unfortunately, the Massachusetts Ocean Sanctuaries Act prohibits the discharge of any municipal wastewater into an ocean sanctuary, and Cape Cod is surrounded by ocean sanctuaries defined in the legislation. The legislation is strictly imposed and a variance is only available to communities that have an existing municipal wastewater discharge to an ocean sanctuary.

Effluent disposal using an ocean outfall has the following advantages:

- No large land area requirements.
- Protects the groundwater and coastal estuaries.

It has the following disadvantages:

- Special legislation, possibly at the federal level, would be required to obtain permits.
- Extensive design and permitting requirements, depending on the location of the discharge.
- Possible high public opposition due to perception that the ocean was being polluted.
- Potential reduction in aquifer recharge, which can lead to saltwater intrusion to wells.

F. **Wick Well Technology.** Wick technology is a relatively new and innovative approach to treated wastewater disposal. Wick technology entails the use of larger (3- to 6-foot diameter) wells dug to the water table aquifer (see Figure 15). The wells are filled with stone, and treated wastewater is discharged over the stone to infiltrate under gravity flow into the underlying aquifer.

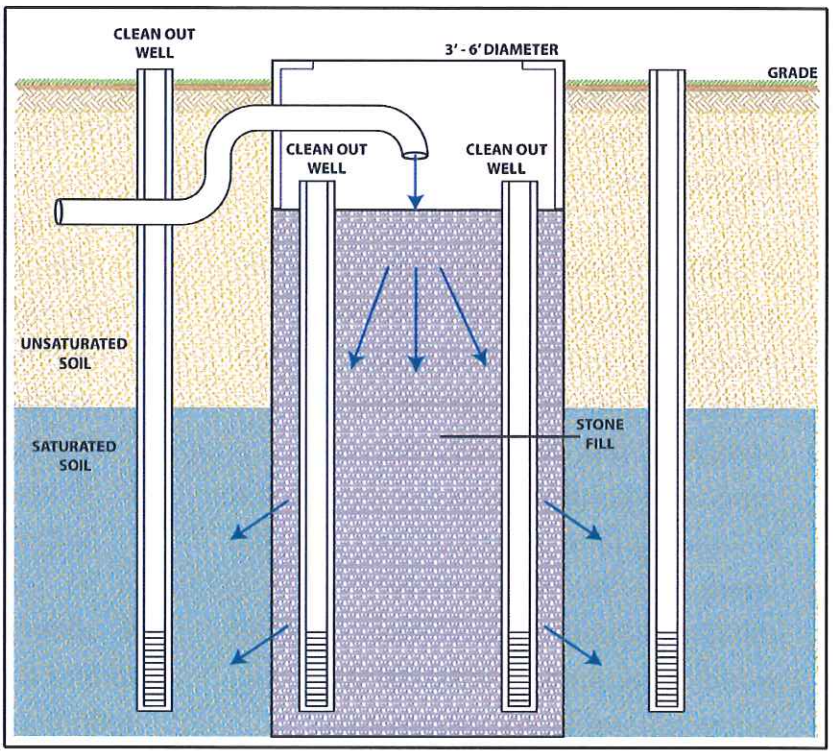

Figure 15 - Schematic of a wick well

There are two wick well installations in southeastern Massachusetts as described in detail below.

In 1997, the Town of Fair Haven, MA installed four disposal wells at their West Island facility. The West Island facility is a small neighborhood plant that serves about

380 homes. Daily flows range between 15,000 and 25,000 gpd. Three of the wells are open, gravity drained wells. The fourth well is referred to as a wick well. The only difference between the open wells and the wick well is that the wick well is filled with stone. At the time of installation, MADEP required Fair Haven to place the stone in the well. The regulatory rationale is uncertain; however, it has been attributed to MADEP being reluctant to permit an "injection well," and the stone fill may have made the disposal system a "wick well" and hence more acceptable. MADEP has since been more receptive to injection wells.

The Fair Haven wells are approximately 23 feet deep, 12 inches in diameter, and set in gravel caissons approximately 4 feet in diameter. The well screens are 1-1/2 to 2 feet long and are set in a favorable sand and gravel layer that is approximately 3 feet thick.

Flow into the Fair Haven wells ranges from 15,000 gpd in the off-season to a seasonal peak of about 25,000 gpd in the summer. The maximum flow to the wells on any given day has been 40,000 gpd. Typically, all of the flow goes into one well at a time. Those three daily flow rates represent 10 gpm, 17 gpm and 27 gpm average daily flow rates, respectively. However, Fair Haven reported wastewater is discharged to the wells in batches rather than flowing at a uniform rate all the time. So while the wells are actually operating, they are flowing at a rate of about 70 gpm for short periods of time (a few hours).

The wick well underwent a long-term clear water test when it was constructed. A flow of 100,000 gpd was pumped into the well for a period of 30 days, or an average rate of 70 gpm.

As stated above, all of the wells are used intermittently. The wick well has not been in service for about two years. After the wick well had been turned off for a period of time, it became plugged, apparently due to non-use, and has not been used since. The well has not been reconditioned, although reconditioning is planned for the future. The open wells (non-stone-filled) continue to operate as designed.

A second wick system was recently installed by a private developer of a small development in Hingham, MA. The system has just become operational at very low rates (a few thousand gpd based on the most recent information received from

MADEP) and therefore there is currently little operating history.

This system currently has three wick wells, and the engineering report claims that each well has a 300,000 gpd capacity, which is consistent with the test rate reported. MADEP approvals documented the understanding that the system may foul in the future and required that well rehabilitation needed to be addressed in the O&M plan. MADEP encouraged the installation of multiple cleanout/treatment wells.

Additionally, because it is an unproven technology, MADEP required an area be set aside for a conventional backup system (beds or leachfields) with a capacity equal to the permitted flow. It was not necessary to actually build the backup system; however, the developer chose to build it at that time so as to not damage the overlying golf course sometime in the future.

The Hingham treatment plant has an ultraviolet (UV) disinfection system as required by MADEP for pathogen/risk assessment concerns. It was recognized that the UV treatment does not leave a residual to mitigate biologically sourced plugging.

Effluent disposal with wick wells has similar advantages and disadvantages to injection wells. Advantages include:

- The land area required would be much less than the area required for infiltration beds, subsurface infiltration, and spray irrigation. The effluent discharge would occur below the surface, and the surface would have minimal disruption.
- Discharge points (wells) could be spread over a large area to minimize groundwater mounding.
- High public acceptance.

Disadvantages include:

- Effluent filtration is needed to provide a high level of nutrient and solids removal to minimize plugging in the wells.
- Relatively unproven technology in Massachusetts. Limited performance data is available.

G. **Wetland Restoration.** In recent years a new innovative technology/management concept has been considered. It is the conversion of abandoned cranberry bogs or previously modified wetlands to more diverse wetland settings that can accommodate and benefit from increased

hydrologic flow. Its primary purposes are to improve water quality of the groundwater flowing through the wetland and restore hydrologic balance to areas that have been impacted by drinking water withdrawals. It can provide natural nitrogen attenuation and thereby protect downgradient marine waters. It can also provide improved wildlife habitat and open space and recreational areas.

This concept has significant regulatory permitting challenges due to national, state, regional, and local wetland protection regulations that have been written to prevent any modifications to wetlands. Many regulators, municipalities, and citizen groups now recognize the water quality and wildlife habitat benefits of converting previously disturbed monoculture cranberry bogs to more diverse wetland settings and are working to overcome the regulatory constraints. The concept has been developed and promoted by the MEP as a way to increase natural nitrogen attenuation in the watershed. It is also being considered as a way to reintroduce highly treated wastewater into watersheds that have been impacted by water withdrawals.

Several wetland restoration projects are envisioned or underway on Cape Cod as briefly summarized below.

The 2003 Technical Report by the Massachusetts Estuaries Project for the Town of Chatham Embayment System (MEP, 2003) summarized MEP's evaluation of several alternatives to improve tidal flushing and/or provide wetland restoration to the Muddy Creek/Monomoy River. This water body and wetland system runs along the Chatham and Harwich boundary and empties into Pleasant Bay on the eastern end of Cape Cod (see Figure 16).

Figure 16 - Aerial photograph of the Muddy Creek area, Chatham, MA, showing location of proposed dike

The MEP found that reconstruction of a historic dike in the upper portion of the creek (and other improvements to re-establish a herring run) could reduce nitrogen to Pleasant Bay from this watershed by 40 percent, or approximately 2,800 kg/year. This same level of nitrogen removal by conventional wastewater treatment techniques would cost significantly more, would have environmental impacts during construction, and could (depending on the wastewater management strategy used) relocate water out of the watershed. The Chatham Health and Environment Department has initiated discussions to determine the regulatory feasibility of reconstructing the dike with a fish ladder; to date, many regulatory agencies are interested and are investigating ways to find an acceptable solution.

The 2004 Technical Report by the MEP for the Popponesset Bay watershed (MEP, 2004) discussed possible nitrogen attenuation through wetland restoration efforts in the Popponesset Bay watershed. These concepts are being pursued through a USEPA-funded project coordinated by MADEP. To date, various abandoned cranberry bogs and other disturbed wetlands have been identified and potential restoration concepts are being developed (i.e., construction of ponds and more varied wetland settings).

The Towns of Barnstable and Yarmouth are currently investigating a potential reuse concept to recharge the groundwater upgradient of an abandoned cranberry bog in the Lewis Bay watershed (see Figure 17).

Figure 17 - Aerial photograph of the Lewis Bay area, Hyannis, MA, showing abandoned cranberry bog being considered for restoration

This wetland system is currently impacted by a drinking water withdrawal of approximately 1 mgd upgradient of the abandoned bog. The withdrawal is affecting base flow through the watershed and

wetlands. The Towns' evaluation will consider the advanced treatment needed for regulatory approval as well as wetland restoration effort to restore the wetland to a more natural setting and provide natural nitrogen attenuation.

H. **Technology Summary.** Rapid infiltration beds are a simple and reliable effluent discharge technology with relatively low operating costs. With the exception of the well technologies, sand infiltration beds have the lowest land requirement.

Subsurface infiltration facilities are simple and reliable. These facilities are constructed below ground and therefore have minimal visual impacts, reduced potential for odors, and allow secondary use of the land. Effluent discharge in subsurface infiltration facilities has higher land area requirements. Subsurface infiltration facilities are not easily cleaned; therefore, the life of the facilities will be dependent on the quality of the effluent.

Spray irrigation (conventional and drip) is a simple and reliable effluent discharge technology with relatively low construction costs. It can provide additional nitrogen uptake and removal. Large areas of land are required and irrigation time is limited by wet and freezing weather.

Effluent discharge through well injection has relatively low land requirements and relatively low construction costs. Injection wells have the potential of plugging at the injection point due to biofouling and buildup of fine solids, and treated wastewater would likely require chlorination. This method does provide a means of effluent disposal at multiple potential sites with minimal land requirements; however, MADEP's resistance to support and permit this technology at this time is an obstacle.

Effluent discharge through wick well is a variation of well injection and has similar advantages and disadvantages. It is attaining limited regulatory acceptance, and more complete acceptance is contingent on long-term demonstration of effectiveness.

Wetland restoration effluent discharge and nitrogen attenuation concepts are being evaluated on Cape Cod and include evaluation and modeling of very site-specific considerations. If they prove to be feasible and acceptable to the regulatory community, they could be low cost methods

to discharge highly treated effluent, recharge impacted portions of the watershed, and attenuate nitrogen in the groundwater.

In summary, there is no universally defined best technology. The best technology is a function of the priorities of the municipality selecting the system, the land available for disposal, and very site-specific constraints and opportunities of the potential discharge/reuse sites.

2.3 Reuse Of Reclaimed Wastewater

As discussed previously through the identification of alternative technologies, municipalities should consider whether there are any viable reuse opportunities when evaluating methods of disposal of treated wastewater

Reuse, reclamation and recycling are often used interchangeably in discussions on water reuse, and sometimes there is little consistency in the use of the terminology from one agency or region to another. For the sake of consistency of understanding, definitions provided by Takashi Asano, a leader in reuse studies, will be utilized in this discussion.

A. **Wastewater Reclamation.** The treatment or processing of wastewater to make it usable.

B. **Water Reuse.** The use of treated wastewater for beneficial purposes such as agricultural irrigation and industrial cooling.

1. **Direct Reuse.** Implies the existence of pipes or other conveyance facilities to deliver reclaimed water

2. **Indirect Reuse.** Discharge of an effluent to receiving water (surface or ground) for assimilation and withdrawal downstream, which is recognized to be important but does not constitute planned direct reuse.

C. **Reclaimed Water.** Treated effluent suitable for an intended water reuse application.

D. **Recycled Water.** Normally involves one use or user, with the effluent from the user being captured and redirected back into that use scheme, typically an industrial practice. The relevance of reuse to Massachusetts was articulated by MADEP in May 1999 in their *Interim Guidelines on Reclaimed Water*. In this document, MADEP acknowledges that:

> "despite our relatively wet climate, many parts of Massachusetts are suffering the impacts of over-stressed, over-utilized water resources....One of our state's approaches to addressing water resource deficits is to promote and encourage the innovative reuse of treated wastewater while continuing to consider the public's health as the controlling factor."
> "We embrace the concept of reclaimed water use and recognize the fiscal, environmental and social benefits of doing so. Development patterns in Massachusetts and specific hydrogeologic setting that are not suitable for water withdrawals or wastewater disposal make the use of reclaimed water an attractive and necessary option."

Evidence that reuse is applicable to Cape Cod and eastern Massachusetts exists. Two examples include: (1) One town has had to abandon a production well because of saltwater intrusion; and (2) Several water purveyors have groundwater supplies that are stressed in dry times, especially during high summer usage.

These purveyors reportedly support the discharge of treated wastewater in a manner that would recharge the aquifers they withdraw from as long as sufficient quality measures are in place.

MADEP's *Interim Guidelines on Reclaimed Water* defines three types of reuse, each of which has particular treatment and quality requirements.

1. **Urban Reuse - Irrigation.** This refers to the use of treated wastewater for irrigation for golf courses or general landscaping.

2. **Urban Reuse - Toilet Flushing.** This refers to treating water to a level that makes it acceptable for toilet flushing. This is allowed in commercial establishments only.

3. **Discharge Into Zone IIs.** MADEP considers groundwater recharge that occurs in the Zone II of a community water system as reuse. As such, MADEP has treatment and quality guidelines for water that is recharged into Zone IIs. Additionally, MADEP discriminates between recharge that is within versus beyond a two-year groundwater travel time of public supply wells. Discharge within the two-year travel time is discouraged by MADEP, but can be permitted under special circumstances and has higher quality requirements.

Reuse for irrigation should be considered when feasible, although weather in Massachusetts is a significant constraint. Storage or alternative discharge methods must be available for winter and wet weather. An appropriate location for application of spray irrigation is in the resort areas of Cape Cod, where population and water use increase considerably in the summer months. The excess flow can be reused through spray irrigation. In the winter, when spray irrigation is not practical, that excess capacity is not required and another conventional treatment system can be used.

When new commercial developments are being planned, reclaimed water systems for flushing should be considered.

A form of indirect reuse has been implemented at one southeast Massachusetts development and is being considered for a northeast Massachusetts industry. This entails recharging groundwater upgradient from irrigation wells. As irrigation water is needed, it can be pumped from the recharged aquifer, thus having less impact on other municipal water supplies or aquifer water levels. In terms of regulatory framework, this is not defined as reuse and therefore quality requirements are not as stringent.

When siting treated wastewater discharge sites, consideration should be given to locating sites upgradient from and in the Zone IIs of municipal supply wells. This practice helps to replenish aquifers that supply water to the municipal wells. Many of the candidate locations for wastewater discharge in Cape Cod towns lie in Zone IIs. Development of these sites should be encouraged by regulators and the municipalities, rather than promoting discharge at sites that results in nearly direct subsurface flow and discharge to coastal waters. This has the combined benefits of replenishing the water supply and reducing nutrient migration to coastal estuaries.

SECTION 3 - THE PROCESS OF SITE SCREENING, IDENTIFICATION AND SELECTION

3.1 INTRODUCTION

Finding a suitable site for the disposal of treated wastewater is a complex process and a number of factors must be considered. A number of criteria must be considered when identifying a site. It is

appropriate to involve all stakeholders in the process, including the lead municipality; the Cape Cod Commission (on Cape Cod); the MADEP (in Massachusetts); and very importantly, the citizens of the community, both through public information programs and formal citizens advisory committees that can represent the interests and concerns of the residents in the formal selection process. Increasing the challenge is the fact that there is progressively less land available and, as more communities seek to improve their wastewater management programs through centralized neighborhood or cluster plants, more land will be needed for disposal. Associated with that challenge is the fact that land costs are steadily increasing.

The following sections provide a guide for identifying and selecting wastewater discharge sites. The process is summarized in the outline below.

Phase I - Preliminary Screening
- a. Site Identification
- b. Site Comparison and Ranking
- c. USGS or ModFlow® modeling

Phase II - Site Characterization and Selection
- a. Planning and Work Plan Development
- b. Field Investigation Tasks
- c. Data Interpretation
- d. Subsequent Testing
- e. Conceptual Design
- f. Public Participation
- f. Final Selection

This process is often not a linear step-by-step process. Often, two or more of these steps will be completed at the same time to meet project timelines.

Detailed descriptions of each task follow.

3.2 Phase I - Preliminary Screening

A. **Site Identification.** The preliminary screening phase is the first step in identifying suitable sites for wastewater disposal. Depending on each town's individual circumstances, this process may take one of two forms: (1) area-wide characterization; or (2) individual site identification.

Both methods have been successfully used to identify candidate sites for Cape Cod towns. The first method, area-wide characterization, is suitable for large towns with many potential suitable areas. The focus of the preliminary evaluation is to apply exclusion criteria to eliminate areas

of town that are not suitable, and then identify and characterize the available sites in the areas that remain. The second method (individual site identification) is more suitable to smaller towns or towns with a minimal number of available parcels of sufficient size to meet the town's wastewater discharge needs. In this approach, the limited number of available sites are identified and then screened with a number of evaluation criteria to determine which are acceptable, and of those, which are preferable.

1. **Area-wide Characterization.** As will be described in greater detail in the Case History section of this report, the Town of Barnstable completed an area-wide characterization. The area-wide characterization is very much simplified if a Geographic Information System (GIS) and associated database is available. If the town does not have a significant GIS database, a great deal of information can be obtained from the MASSGIS database available on the internet. The specific details of this project will be described in the Case History section, but the general process is described below.

Potential evaluation criteria are identified. Evaluation criteria may be exclusionary or may just be criteria for determining or ranking suitability. Examples of evaluation criteria include, but are not limited to, determining the proximity of:

- Wellhead or groundwater protection areas (as defined and determined by the municipality) or Zone Is or Zone IIs as defined by documentation submitted to MADEP. Recharge is not allowed in Zone Is. Recharge is allowed into Zone IIs, but entails greater regulatory scrutiny and additional monitoring requirements.

- **Areas of Critical Environmental Concern (ACECs).** ACECs have development and alteration limitations that would be applicable to wastewater discharge facilities.

- **Surface Water**. Surface water can be impacted by recharged wastewater, particularly with respect to nutrient impacts.

- **Vernal Pools.** Water levels in vernal pools can be affected by recharge. Hence, the sensitive ecology of the systems can be impacted.

- **Wetlands.** Hydraulic as well as chemical effects of groundwater recharge can impact sensitive wetland environments.

- **Areas of Rare and Endangered Plant and Wildlife Species.** These areas have building, development and alteration limitations that would be applicable to wastewater discharge facilities.

- **Conservation Areas.** Conservation areas are set aside to limit development. Some types of wastewater facilities would likely not be consistent with that land use.

- **Flood Hazard Zones.** Wastewater discharge facilities can not be located in flood zones due to potential facility damage during floods.

- **Shallow Groundwater.** Sufficient depth to groundwater must be maintained so the functioning of the discharge system is not jeopardized; flooding and runoff do not occur; and subsurface structures on proximal properties, such as basements or septic systems, are not impacted.

- **Groundwater Impacted by Oil or Hazardous Waste Releases.** Mounding resulting from recharge can alter groundwater flow paths and subsequently the migration of existing groundwater contamination.

- **Areas of Low Hydraulic Conductivity.** Areas of low hydraulic conductivity must be avoided to assure proper dispersion of recharged water.

- **Existing Treatment Plant.** Proximity of the treatment plant is a factor when considering pipeline costs.

The special consideration areas related to the above criteria are typically plotted on town maps through a GIS system, the MASSGIS database, or manual plotting. Some of the criteria listed above are considered exclusion criteria; that is, it is very unlikely that a discharge facility could be permitted in the area. Other criteria are more for evaluation, such as the location of Zone IIs or distance from the treatment plant (see Figure 18).

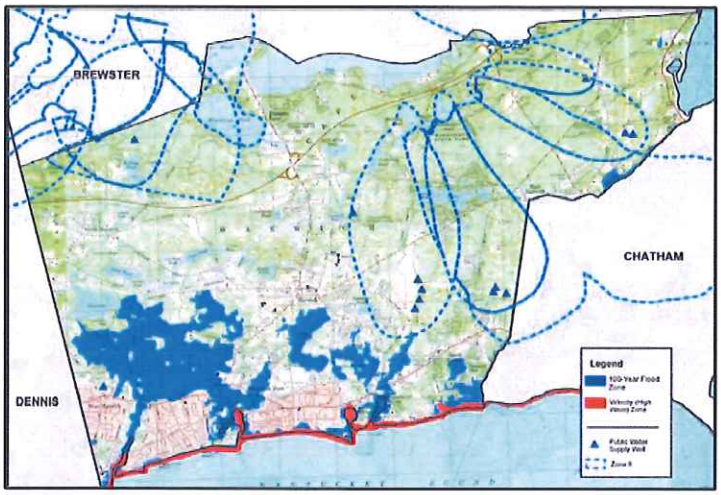

Figure 18 - MASSGIS map showing selected evaluation criteria

Locations within exclusion criteria areas should be eliminated from further consideration. Available areas for candidate sites can then be identified as those outside the exclusion areas.

Through the use of either a GIS database or available town mapping, specific sites can be identified using parcel maps. Undeveloped, town-owned, or potentially available parcels or groupings of parcels of sufficient size should be identified at this time.

2. **Individual Site Identification.** There is an alternative approach to conducting the town-wide characterization, which may be more suitable for smaller towns where the locations of likely available parcels is already known or easily determined by knowledgeable individuals or professional town staff (Town Planner, Health Agent, DPW Director, Water Superintendent, etc.). This type of site selection approach was used by the Towns of Chatham, Mashpee, and Falmouth.

In using the approach, potentially available parcels are identified as a first step using existing town mapping, a GIS database, or general knowledge of the town properties. Screening and characterization of the sites is completed in a subsequent step.

Whichever preliminary approach is used, this step culminates in a listing of candidate sites that are potentially suitable for discharge.

B. **Site Comparison and Ranking.** In either case, a useful tool at this point is the preparation of a matrix that will facilitate evaluation and comparison of sites. Although a number of sites may be acceptable, some may have features that make them more suitable than others. As a result, sites are ranked with respect to suitability. Characteristics that make one acceptable site more suitable than another

acceptable site include distance from the treatment plant (i.e., required force main length), compatibility with surrounding land use, watershed and nutrient loading impacts, reuse potential, and soil characteristics.

Tables 3-1 and 3-2 are examples of matrices that were developed by a Cape Cod town to characterize and rank sites identified through the Individual Site Identification approach. Table 3-1 serves as a qualitative review of site characteristics, and on Table 3-2, site characteristics are quantified and scored. The scoring serves to eliminate sites and to rank the remaining sites. To aid in ranking the sites, the scores may be weighted. The weighting scale is subjective and each town should develop their own scale based on their priorities. Examples of weighting are that the distance from the treatment plant may have minimal impact, so it has a weighting of 10 percent, while abutting land use may have a higher weighting of 25 percent. At the end of this step, a listing of potential available sites is developed.

An important task at this point, or at a previous point in the evaluation, is to conduct site visits. It is easy to think that mapping data provides all of the needed information. However, a site visit to observe, for example, actual topographic features, abutting land use, and presence of surface water is important and can exclude sites that, on paper, may seem suitable.

Based on the financial resources of the town and the expected land area requirements, the town now determines how many sites should have detailed characterizations completed. This is a discretionary decision reached by the town, potentially in conjunction with its consultant and its citizen advisory group. If there is one site that is clearly superior to others with sufficient area to meet the town's discharge needs, it may be necessary to evaluate only that single site. If there are multiple sites that could meet the needs of the town, or if more than one site is needed to provide the necessary capacity, multiple sites may undergo a detailed characterization. At the end of this step, the town will have decided which site(s) will have detailed characterizations completed.

C. **USGS Modeling.** Comprehensive wastewater management planning studies currently underway on Cape Cod have utilized groundwater modeling performed by the USGS to assess candidate discharge sites. USGS modeling has been a service

provided by Barnstable County to assess groundwater and nutrient flow impacts that would result from the proposed recharge scenarios. USGS modeling as a county service is only available for a limited time (planned completion in October 2005); however, the model is in the public domain and can be used by towns in the future for their individual studies. The USGS model was previously developed for other water supply and water resource protection studies on Cape Cod. For the CWMP studies, the existing model was adjusted on a case-by-case basis for the towns. Although modeling by the USGS may not be available in the future, or not available at all to municipalities in other states, groundwater modeling at this step in the process can be a valuable assessment tool and should be considered, independent of access to the USGS program.

To use the model to assist in site evaluations, a projected flow is modeled at a candidate discharge site. The USGS model simulates the degree of mounding that would occur and uses ModFlow's® particle tracking function to simulate the flow direction of groundwater and associated nutrients in the subsurface. The model output is exported to GIS mapping to facilitate review of the results. The particle tracking shows the fate of recharged water and where recharged water intercepts surface water bodies, coastal waters, Zone IIs, and public supply wells for these flows. This information is valuable for site screening or subsequent environmental impact analysis. The model can account for the flows (measured in gpd) that recharge these various sensitive receptors and calculates a travel time estimate. The modeling provides significant insight into the potential impacts of recharge at the candidate sites and is a valuable characterization tool that is best incorporated prior to the investment in field investigations (see Figure 19).

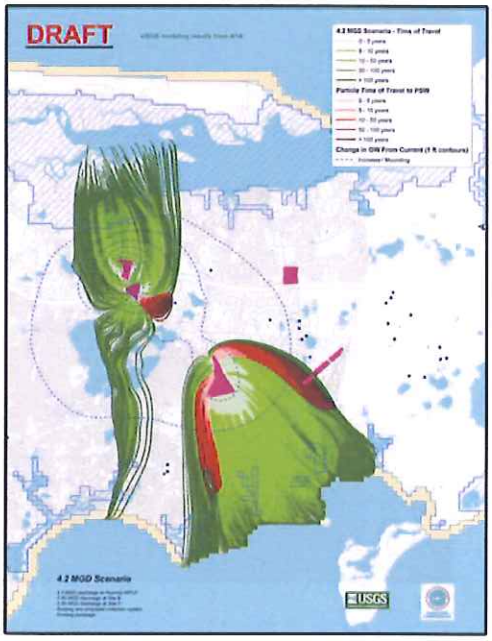

Figure 19 - USGS model output showing site of proposed recharge and fate of recharge water

3.3 Phase II - Site Characterization And Selection

A. **Planning and Work Plan Development.** At the end of Phase I, one or more sites will have been selected for further characterization to verify suitability. Information gathered to date on the site is typically from generalized sources such as town-wide mapping, U.S. Department of Agriculture (USDA) soils mapping, and other sub-regional mapping or data. The purpose of the site characterization step is to obtain very site-specific information related to soil types, depth to groundwater, and hydraulic conductivity. These site characteristics are typically defined with a subsurface investigation program using test borings, observation wells, and test pits.

The first step in the planning and work plan task is to define the specific objectives of the testing. The second step is a site visit to assess topography, physical access, and locations for testing. If the property is not owned by the town, arrangements must be made with the landowner for accessing the site. Provisions may need to be made to clear a temporary road into the site that will allow entrance of backhoes and other equipment.

A work plan should be developed that describes the proposed work. At this point, the town should seek feedback from MADEP regarding plans to evaluate sites. This is not a regulatory requirement and is not always done, but if the town desires a level of comfort that MADEP concurs the site warrants further investigation, this step can be taken.

B. **Field Investigation Tasks.**

1. **Borings.** One to three soil borings should be completed to characterize soil types and determine depth to water. Borings should be advanced at least 10 feet into groundwater. If regional data or literature indicates an aquitard (low permeability layer) or bedrock is potentially present at a depth that could impact system performance, the borings should extend to that depth.

2. **Wells.** If soil conditions revealed by the borings do not rule out the site being used, one or more of the borings should be completed as observation wells. If groundwater flow direction is an important consideration and not yet clearly defined, at least three wells should be installed to allow a

determination of flow direction (see Figure 20).

Figure 20 - Completing soil borings to characterize deep soils and aquifer characteristics

After wells are completed, they can be used to estimate hydraulic conductivity of the receiving aquifer through the use of slug tests. These are relatively simple in situ hydraulic conductivity tests that remove small quantities of water from the wells(s) and then measure the time for the well to return to its original water elevation. Due to the uncertainties inherent with slug tests, multiple tests should be completed in each of the wells present. Often, slug tests are very localized and may yield data that is not representative of the soil types present. In this case, it may be more appropriate to estimate hydraulic conductivity based on soil types or obtain estimates from regional studies completed by the USGS.

The USGS has completed groundwater modeling across Cape Cod and has assigned hydraulic conductivity values to the aquifers. Although their information may not be as site specific as on-site testing, it may provide reliable data. If there is not yet sufficient data to be certain that the hydraulic conductivity is adequate for the proposed flow, large volume pumping tests can be completed which can yield much more accurate hydraulic conductivity data. During these pumping tests, large quantities are pumped from a large diameter well (4 to 6 inches). The water table drawdown in a nearby observation well is measured and used to calculate hydraulic conductivity.

3. **Test Pits and Percolation Tests.** If RIBs or a subsurface leaching system is the likely technology choice, test pits and percolation tests should be completed to characterize shallow soils. Test pits should be completed by a certified soil evaluator so that the records are suitable for permitting purposes. Percolation test data should be used to determine whether infiltration rates will be sufficient for the proposed facility (see Figure 21).

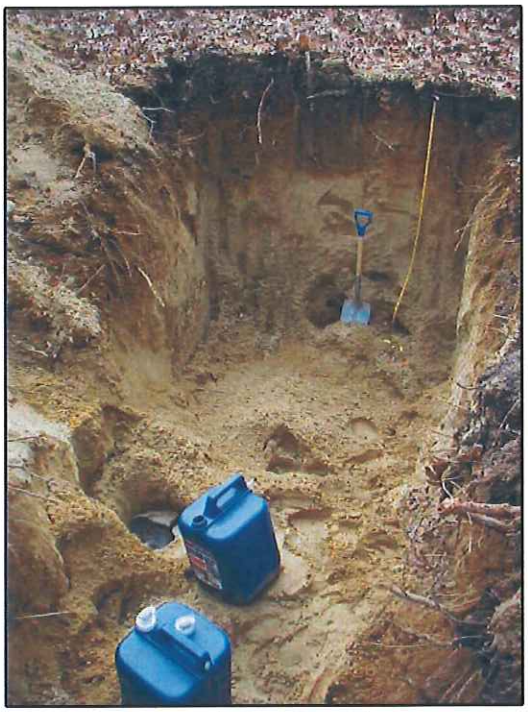

Figure 21 - Completing test pits and percolation tests

Eventually, if the site is selected for use, a groundwater discharge permit will be required. A significant amount of site testing is required to obtain a such a permit, including multiple wells, water quality testing, multiple test pits and percolation tests, along with additional evaluations using the obtained data. The site characterization tasks described above may contribute to the permit requirements, but may not meet them all. Therefore, it is important to have all investigations and analyses performed as part of the characterization to meet the permit process quality requirements. That way, the data can be used for (and in conjunction with additional data) MADEP permitting. Prior to completing the investigation, the town should determine whether it wants to invest in all the permit requirements at this early stage and avoid returning to the site again, or to defer some of the requirements until a later date, and complete the site characterization for a lesser investment.

C. **Data Interpretation.** Data from the field work is interpreted to make a determination regarding the suitability of the site. Factors to be considered include depth to seasonal high groundwater; deep hydraulic conductivity; and the resultant mounding analysis, percolation rate, and groundwater flow rate and direction. Each is discussed below.

1. **Depth to Seasonal High Groundwater.** Depth to groundwater and depth to seasonal high groundwater are determined with the wells and/or test pits. Standing water in either the well or test pit is the current groundwater level. Care must be taken to determine if perched groundwater is present. Seasonal high groundwater may be much higher than the measured groundwater level and soil

mottling (discolored soil above the current groundwater level) in either the test pit or the soil samples from the boring often represents the level of seasonal high groundwater. Seasonal high groundwater elevations can also be estimated through a calculation methodology described in a CCC and USGS guidance document (Frimpter, Belfit, 1992). This methodology utilizes historic groundwater data in a series of Cape Cod index wells to estimate seasonal high groundwater at most locations on Cape Cod. Depth to seasonal high groundwater is important because MADEP requires that groundwater remain 4 feet below the bottom of sand beds or leaching facilities in its highest level, including mounding impacts.

2. **Deep Hydraulic Conductivity and Mounding.** Deep hydraulic conductivity controls how efficiently the underlying aquifer will drain the recharged effluent effluent and what the mounding effects will be. The hydraulic conductivity data is used to calculate the potential mounding that will occur.

Multiple methods of calculating mounding are available in hydrogeology textbooks. Another option which MADEP uses is a relatively simple, commercially available, analytical calculator, referred to as the Hantaxis model, to calculate mounding. Model input includes recharge rate, recharge area, hydraulic conductivity, depth to water, and porosity, and creates a table and graphic of the mounding impacts (see Figure 22).

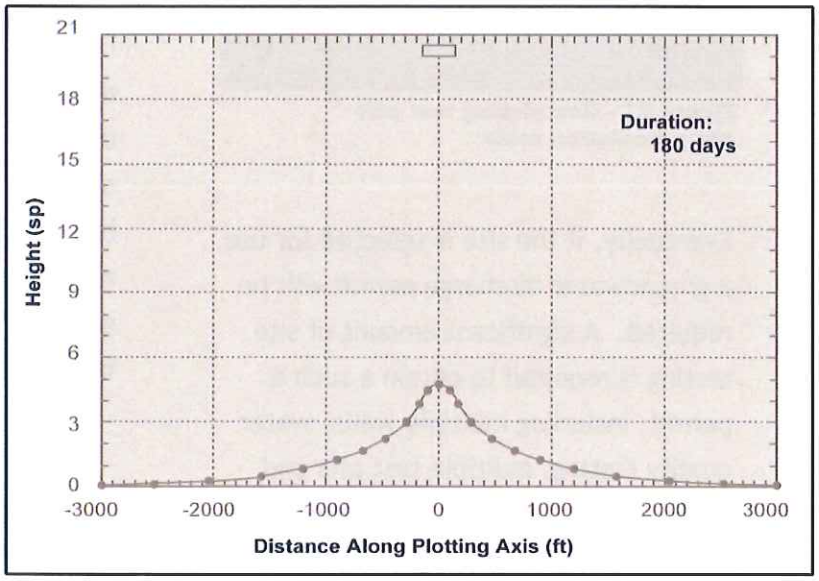

Figure 22 - Output from analytical calculator

An alternative is to complete a relatively simple numerical model using such commercially available software as ModFlow. Although there is generally insufficient data to develop a comprehensive groundwater flow model, a tool such as ModFlow can serve to develop a mounding estimate.

A number of Towns on Cape Cod have integrated regional groundwater modeling performed by the USGS into their site evaluation programs. The integration of USGS modeling was described in Section 3.2.

3. **Percolation Rates.** MADEP defines loading rates for RIBs and subsurface infiltration systems, measured in gpd/sf based on recorded percolation rate ranges. Table 3-3 summarizes MADEP guidance for determining acceptable loading rates. This calculation is important because it ultimately defines the capacity of a given area of land.

4. **Groundwater Flow Rate and Direction.** Groundwater flow rate and direction can be determined from sub-regional data or from data obtained during the investigation. Groundwater flow direction is determined from the relative water levels in at least three on-site or proximal wells. Groundwater flow rate is a function of hydraulic conductivity and water table gradient. Flow direction is important to identify environmental or human health receptors of the treated effluent. Flow rate is important when proposed facilities are in a Zone II to determine if the site lies within a two-year travel time of public supply wells and therefore if higher levels of treatment are required.

Again, regional modeling performed by USGS may be used to aid in determining the potential impacts of the proposed recharge facility, particularly with respect to the fate and migration of nutrients.

TABLE 3-3

MADEP GUIDANCE FOR DETERMINING HYDRAULIC LOADING RATES

INFILTRATION FACILITY TYPE	RECOMMENDED HYDRAULIC LOADING RATE (GPD/SF) FOR THREE RANGES OF PERCOLATION RATES		
	LESS THAN 5 MIN/INCH	5 TO 10 MIN/INCH	10 TO 20 MIN/INCH
Open sand beds	5.0	4.0	2.0
Leaching pits	3.0	2.5	1.5
Leaching chambers	3.0	2.5	1.5
Leaching trenches	2.5	1.5	1.0

From "*Guidelines for the Design, Construction, Operation, and Maintenance of Small Sewage Treatment Facilities with Land Disposal,*" MADEP, 1988.

D. **Subsequent Testing.** At the completion of the data interpretation, subsequent testing may be warranted. After the initial characterization, a site may seem suitable, but additional hydraulic characterization is needed to verify the site's capacity to accept the quantity of water proposed for the site. This is typically needed for sites located in the moraine areas of Cape Cod where soils are denser and highly variable.

A suitable test for this phase of evaluation, applicable to RIBs or subsurface infiltration systems, is a hydraulic loading test. Guidance for conducting loading tests is provided in the USEPA *Process Design Manual - Land Treatment of Municipal Wastewater* (1981). Loading tests entail constructing pilot-scale loading basins, a minimum of 10 feet in diameter. Larger diameter basins up to actual proposed size can be constructed, but USEPA recommends a minimum diameter of 10 feet. Loading tests are performed by saturating the soils at the basin and conducting a number of constant head and falling head evaluations to determine the soil's capacity in gpd/sf. USEPA guidance (USEPA, *Process Design Manual - Land Treatment of Municipal Wastewater*, 1981) suggests that a design infiltration rate for recharge facilities be 4 to 15 percent of the measured maximum infiltration rate as determined in loading tests. The range is a function of physical soil properties, and generally an average design factor of 10 percent is suitable. Given the generally innovative nature of

injection wells or wick wells, pilot testing is warranted for the technologies before designing and constructing full-scale systems.

E. **Conceptual Design.** Once sites are characterized in terms of available area, topography, and application capacity, discharge technologies should be matched to the sites. It is likely that early in the investigation, based primarily on the size of the site or the neighboring land use, it was known whether a site was most suitable for subsurface leaching, rapid infiltration beds, spray irrigation, or injection and/or wick wells,

Spray irrigation is viable where large tracts of open fields or woodlots are available, but again, in the Northeast, spray irrigation alone is not a viable alternative. It can be used in conjunction with other methods at other locations.

It is likely that if wick wells or injection wells have been selected, and the operational and regulatory hurdles of those technologies are understood and accepted, that smaller parcels have been identified for siting those particular technologies. It must be remembered that MADEP requires a reserve area for a conventional technology at wick well installations, and it is likely a similar requirement would be made for injection wells.

Wetland restoration would obviously be a predetermined alternative at a site selected specifically for that purpose.

Rapid infiltration beds or subsurface infiltration may be used interchangeably at a site, so a determination would be made at this point as to which alternative best meets the objectives of the town. As discussed in the technology review, RIBs are easier to maintain and may be more reliable over a long period of time. However, they are intrusive on the landscape. Subsurface leaching trenches have operational disadvantages but allow alternative use of the surface and are not as visually intrusive. The decision between the two technologies should be made based on the town's priorities and objectives for the site.

Once a technology is selected, it should be laid out conceptually, keeping in mind the need for perimeter buffers, reserve area, access roads, berms, parking, and ancillary facilities. After the facility is laid out and actual discharge area is determined, the capacity of the site can be defined. The capacity of the site will be one of the

criteria used in the final characterization, ranking, and selection of sites.

F. **Public and Regulatory Participation.** As discussed in Section 3.1, citizen and regulatory participation is a critical component of all aspects of comprehensive wastewater management planning, but especially with the potentially controversial topics of selecting a treated wastewater discharge site. Typically, the initial public perception of a large discharge site is unfavorable, especially to the proximal landowners. Keeping the citizenry involved throughout the process is important so they understand the need for a site, the likely candidate sites, and the rationale for selecting the favored site.

Citizen concerns will need to be addressed through design features that mitigate environmental impacts. Ultimately, the acceptance of new effluent discharge facilities and all major components of a town's CWMP will be determined by the formal Massachusetts Environmental Policy Act (MEPA) and Cape Cod Commission Development of Regional Impact (DRI) environmental review process. The public education and participation process must start at the beginning of the CWMP and site screening process to be successful.

G. **Final Selection.** Following the data interpretation task and any supplemental investigations, the suitability of each tested site should be determined. Again, as at the end of the preliminary screening task, it may be appropriate to develop a matrix to compare and rank the tested sites. If one site is clearly the best choice, a matrix may not be warranted. If multiple sites were tested and all prove to be acceptable, a matrix may be warranted to assist the town in determining which site should be the priority for construction. An example matrix prepared for this phase of the site selection process is provided as Table 3-4.

When the final site selection is made, steps toward regulatory approval and implementation can be initiated. If the site is not town owned, discussions should have already taken place regarding acquisition. Final steps in purchasing the site can be taken.

Following MEPA and CCC approvals, a groundwater discharge permit will need to be obtained. Most information for the permit application can be derived from the work completed to date, but as described above, additional investigations may have to be conducted to meet all of the permit application requirements.

TABLE 3-4

SUMMARY OF SITE EVALUATION
Effluent Discharge and Reuse
Guidance Document and Case Study Project
Barnstable County Wastewater Implementation Committee and Town of Barnstable, MA

ALTER-NATIVE NO.	ALTERNATIVE NAME	INFILTRATION LAND AREA (ACRES)	ESTIMATED FACILITY CAPACITY (MGD)	DISTANCE FROM WPCF (LF)	SITE TOPOGRAPHY	SOIL PERMEABILITY (PERCOLATION RATE)	DEPTH TO GROUNDWATER	ABUTTING LAND USE

TABLE 3-4 (continued)

ALTER-NATIVE NO.	ALTERNATIVE NAME	AESTHETIC IMPACTS	PROXIMITY TO SENSITIVE RECEPTORS	CAPITAL COSTS	CAPITAL COST PER MGD ($/MGD)	ESTIMATED ANNUAL O&M COSTS	PRESENT-WORTH COSTS	PRESENT-WORTH COST PER MGD ($/MGD)
B1	McManus site with sand beds	Moderate due to deforestation and image of sand beds	2,700 feet to public water supply wells	$6,200,000	$3,900,000	$180,000	$8,100,000	$5,100,000
B2	McManus site with subsurface infiltration	Minimal after construction	2,700 feet to public water supply wells	$13,000,000	$14,000,000	$180,000	$15,000,000	$17,000,000
C2	Airport site with subsurface infiltration	Minimal after construction	1,100 feet to public water supply wells	$21,000,000	$9,100,000	$530,000	$27,000,000	$12,000,000
D1	Cape Cod Community College site with sand beds	Moderate due to deforestation and image of sand beds	4,100 feet to public water supply wells	$7,000,000	$4,100,000	$190,000	$9,000,000	$5,300,000
D2	Cape Cod Community College site with subsurface infiltration	Minimal after construction	4,100 feet to public water supply wells	$16,000,000	$15,000,000	$220,000	$19,000,000	$17,000,000
E1	Lorusso site with sand beds	Moderate due to deforestation and image of sand beds	2,300 feet to public water supply wells	$3,600,000	$7,200,000	$80,000	$4,500,000	$9,000,000
E3	Lorusso site with spray irrigation	Moderate due to perception of sprayed wastewater	2,300 feet to public water supply wells	Not considered due to low flow	Not considered due to low flow	Not considered due to low flow	Not considered due to low flow	Not considered due to low flow

The site(s) will need to gain MEPA and CCC DRI approvals. If the public and regulatory participation process was successful, all (or nearly all) concerned citizens and regulatory agencies should understand the selection process that has resulted in one or more sites and technologies being selected. They should agree that the selected sites are the bet and should support the decision.

PART 2 - TOWN OF BARNSTABLE SITING EVALUATION AND SELECTION: CASE HISTORY

SECTION 1 - INTRODUCTION

1.1 Background And Purpose

In the mid-1990s, the Town of Barnstable (see Figure 1) initiated efforts to find additional effluent disposal sites. At that time, the Town had completed the Needs Assessment Report of their Comprehensive Wastewater Management Plan, which identified effluent discharge capacity limitations at the Hyannis WPCF site as well as the need to locate additional effluent discharge sites.

The Town has completed the following components of its Comprehensive Wastewater Management Plan (CWMP) as well as the following improvements to the Hyannis WPCF and sewer system extensions as part of ongoing implementation of the wastewater plan:

- CWMP Needs Assessment Report (December 1993).
- CWMP Alternatives Screening Analysis Report (February 1996).
- CWMP detailed evaluations of the alternative solutions (1997 to present).
- Construction of a new secondary clarifier at the Hyannis WPCF (1997).
- Construction of an improved nitrogen removal process at the Hyannis WPCF (2000).
- Construction of several sewer system extensions and improvements on Bearses Way, Route 28, Barnstable Road, Summerside Lane, Norris Street, Center Street, Old Colony Road, and Corporate Drive (1996 through 2004).
- Preliminary design of sewer system extensions around Wequaquet Lake, Long Pond, Stewarts Creek, and Cape Cod Community College areas (2002 to present).
- Groundwater modeling of various effluent discharge sites as part of a collaborative effort between the United States Geological Survey (USGS), Barnstable County, and the Cape Cod Commission (2004 to present).
- Subsurface and feasibility evaluations of several sites to locate additional effluent discharge/reuse capacity (2002 to present).

The Town needs to site additional effluent discharge and/or reuse facilities before additional sewer extensions can occur. The

purpose of this portion of the report (Part 2: Town of Barnstable Siting Evaluation and Selection: Case History) is to briefly present the site evaluation completed by the Town of Barnstable as part of their wastewater planning efforts. The Town presents this history as a case study to assist other towns with their wastewater planning efforts and efforts to site advanced treatment and effluent discharge/reuse systems.

The Town of Barnstable believes that all towns and communities need to work together if they are going to efficiently meet the wastewater treatment needs currently being faced by Cape Cod and other coastal communities.

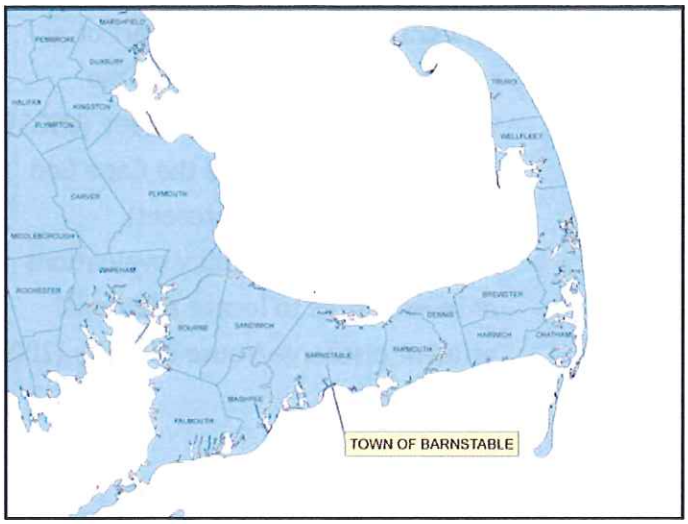

Figure 1 - : Location of Barnstable, MA on Cape Cod

SECTION 2 - IDENTIFICATION AND SCREENING OF NEW EFFLUENT DISCHARGE/REUSE SITES

2.1 First Round Of Screening

The site identification and preliminary screening was performed with the aid of the Town's computerized Geographic Information System (GIS). This system allows the integration of Town geographic information obtained from several aerial and land-based surveys with other databases of information relating to Town resources and activities. The integration of this information allows a Town-wide, multi-level evaluation of criteria. The evaluation utilized the graphical overlay of information to identify and screen sites on the selected criteria. The identification and preliminary screening was a multi-step process using the Town's GIS. The following steps summarize that process.

A. **Step 1.** The GIS was used to search the Town for undeveloped parcels that were 4 acres or greater. A total of 592 parcels were identified. The 4-acre area was used because it was determined to be the minimum area required to discharge a 0.5 mgd

flow, which was established as one of the criteria in the siting process

B. **Step 2.** The total number of identified parcels was reduced by screening out sites which were located in environmentally sensitive areas in which effluent discharge is not allowed. These areas were established by reviewing the recommendations made in the Needs Assessment and in consultation with the Town Department of Public Works, Conservation Department, Planning and Development Department, and Health Department. The following areas were identified:

1. Areas of Critical Environmental Concern (Sandy Neck ACEC).
2. Hyannis Coastal Plain Ponds Complex.
3. Vernal pools.
4. Atlantic White cedar swamps.
5. Rare and endangered wildlife habitat.
6. Rare and endangered plant habitat.
7. Coastal barrier beaches.
8. Coastal barrier beaches with dunes.
9. ZOCs.
10. Conservation areas.
11. Flood hazard zones (Velocity Zones and A Zones).

A base map was created by overlaying the Town boundaries, the location of the WPCF, radial distance in 1-mile increments from the WPCF, assessor's parcel information, and the areas identified above. The parcels identified in Step 1 which are located in the 11 areas were screened out, leaving 207 potential sites.

C. **Step 3.** The third analysis was performed to identify parcels in suitable soils for rapid infiltration beds (RIBs). The USGS surficial geology map was used to determine the general suitability of soils. Sand and gravel deposits and sandy to silty till were accepted, while impervious soils such as clay and silt deposits were not acceptable. Seventy-seven parcels greater than 4 acres, with generally suitable soils for rapid infiltration sand filter beds, were identified. Table 2-1 lists the 77 parcels identified in Step 3, as well as those parcels to be further screened in Steps 4 and 5. The information provided in Table 2-1 includes:

1. **Map, Parcel, and Extension Numbers.** These are assessor's numbers assigned to every property in the Town. The map and parcel numbers are the link used in the GIS for database analysis and graphic illustration.

Notes:

1. Column headings are described in detail in section 8.3.D of the text.
2. Parcel was screened out due to a minimum depth to groundwater of 8 ft. or less.
3. Parcel was screened out due to a minimum depth to maximum high groundwater of 8 ft. or less.
4. Parcel was screened out due the parcel being an open space for an existing subdivision.
5. Parcel was screened out due to the Adjusted Range in Depth to Groundwater rising to within 8 ft. of the ground surface for a modeled discharge of 0.5 mgd.

Table from Wastewater Facilities Plan - Phase II - Alternatives Screening Analysis, Town of Barnstable, MA Stearns & Wheler, 1996, 2004

2. **Owner's Name.** This is the name of the owner of the property from the assessor's records.

3. **Parcel Area.** This is the area of each parcel in acres from the GIS.

4. **Geologic Soil Classification.** This is the geological soil classification, as defined on the Sandwich, Cotuit, and Hyannis USGS Geologic Quadrangle maps, 1975 edition.

5. **USGS Observation Well Number.** The Cape Cod Commission, Water Resources Office (in cooperation with the USGS), maintains a network of 65 observation wells across the Cape. The water levels in these wells are measured monthly and the data is maintained in computer databases by both the Cape Cod Commission and the USGS.

6. **Zone.** This is the zone in which the parcel is located, and the zone is used to determine the annual water level range used to calculate the maximum high groundwater, as developed by Frimpter and Belfit (1992) and described in Section 8.1D.

7. **Reference Water Level June 1992.** This is the depth to groundwater for the USGS observation well in June 1992. This water level is used in combination with the zone to determine the water table adjustment factor.

8. **Water Table Adjustment Factor.** This is a factor used to adjust the groundwater elevation observed in 1992 to a maximum probable high groundwater level. The groundwater elevation observed in 1992 is presented as "Range in Depth to Groundwater," and the maximum probable high groundwater is presented as the "Adjusted Range in Depth to Groundwater."

9. **Range in Depth to Groundwater.** This is the range in depth to groundwater at each parcel as defined by comparing the observed 1992 water table (Geraghty & Miller) with the topography in the GIS. The range occurs because the topography of the site varies, while the water table is relatively flat.

10. **Adjusted Range in Depth to Groundwater.** The adjusted range in depth to groundwater at each parcel is

the range in depth to groundwater, based on the estimate of maximum high groundwater.

D. **Step 4.** A fourth analysis was performed to eliminate any parcels that have groundwater within 8 feet of the surface. The Geraghty & Miller 1992 Observed Groundwater Table Map, Figure 8 of the Groundwater Conditions Report (Geraghty & Miller, 1993), was used for this analysis.

E. **Step 5.** A fifth analysis was performed to review existing land use to determine if any of the remaining parcels were open space parcels for existing subdivisions.

F. **Step 6.** A sixth analysis was performed using hydraulic conductivities from the Groundwater Conditions Report (Geraghty & Miller, 1993) and the groundwater model (Geraghty & Miller, 1992) prepared during the Needs Assessment to establish the "mounded" groundwater level based on an effluent discharge of 0.5 mgd at each parcel. One parcel was eliminated as a result of this analysis.

G. **Step 7.** At this point, members of the Town met with MADEP to review the Town's progress in identifying and screening potential effluent discharge sites. At the request of MADEP, three sites that had been previously screened out were added to the list of sites to receive detailed evaluations.

H. **Step 8.** The eighth step involved consolidating the individual parcels into potential sites and the prioritization of the potential sites. The consolidation of parcels was accomplished by combining the 48 parcels into potential sites by grouping abutting parcels. Included in this effort are undeveloped parcels less than 4 acres that immediately abut the potential sites. Thirty potential sites were formed in anticipation of a more detailed screening in Phase III. The 30 sites were then prioritized to identify those most favorable for effluent discharge sites. The prioritization was based on five factors (listed below), for which various scoring scales were assigned. Additionally, each factor was given a weighting factor to give it a relative importance compared to the other factors. The scales and weighting factors are subjective and based on the priorities of the town completing the evaluation.

1. **Type of Owner.** This is the type of property owner based on assessor's

records. Ownership has been divided into three categories: town, public, and private. A prioritized ranking has been assigned to each of the three categories as follows: Town = 1; Public = 5; and Private = 10. Type of ownership carries a percentage weighting of 15 percent in the final prioritization.

2. **Hydraulic Conductivity.** The hydraulic conductivity values from the groundwater conditions report (Geraghty & Miller, 1993) and the groundwater model (Geraghty & Miller, 1993) prepared during Phase I were used to define hydraulic conductivity at each of the 30 sites. An incremental weighting was given to the hydraulic conductivities ranging from 1 for a site with a hydraulic conductivity of 200 ft/day to 9 for a site with a hydraulic conductivity of 0 ft/day. For each 25 ft/day change in hydraulic conductivity, one point change was reflected in the ranking. Hydraulic conductivity carried a percentage weighting of 20 percent in the final prioritization.

3. **Distance to the WPCF.** Sites closest to the WPCF were prioritized higher within that category than sites farthest away from the WPCF. The ranking for distance to the WPCF is the actual miles recorded from the GIS system. Distance to the WPCF carried a percentage weighting of 40 percent in the final prioritization.

4. **Abutting Land Use.** Each site was evaluated for compatible abutting land use. The Town zoning map and GIS were used to identify abutting land use. Residential land use was considered the least desirable abutting use.

Abutting land use was divided into two categories: (a) residential with a ranking of 10; and (b) non-residential with a ranking of 5. Abutting land use carried a percentage weighting of 5 percent in the final prioritization.

5. **Slope Ratio for Site Topography.** The GIS was used to define the range in distance to groundwater and area of each use. This data was put into an equation to relate the change in distance to groundwater on a site to the overall area of a site. The ranking for the slope ratio was the actual value calculated for each site. Slope ratio for site topography carried a percentage weighting of 20 percent in the final prioritization.

The final prioritization of each site was calculated by multiplying the prioritized ranking by the percent weighting for each of the five categories described above. This resulted in a final prioritized rating for each site ranging from 3 (most preferable) to 7 (least preferable). The prioritized rating was grouped into the following categories for further evaluation of Phase III: primary sites for evaluation (rating of 3); secondary sites for evaluation (rating of 4); and alternative sites for evaluation (rating of greater than 4). There were 2 primary sites, 8 secondary sites, and 20 alternative sites.

2.2 Second Round Of Screening

The results of the first round of screening were reviewed through the public participation process. After receiving all comments, the Town conducted a revised screening. In the second round of screening, a process similar to the first round was utilized. A nine-step screening process was used and, as in the first round, was based primarily on data available in the Town's GIS database. The screening was started using the assumption that the entire Town was available for land disposal. The screening process excluded or prioritized candidate sites by evaluating areas with respect to the criteria described for the first round. The second round entailed the following steps:

A. **Step 1**. The GIS database was used to map Zone IIs, groundwater protection areas and wellhead protection areas. In the time between the first and second screening efforts, MADEP became more receptive to treated wastewater discharge in Zone IIs. Although MADEP strongly discouraged recharge in Zone IIs in the early stages of the facilities planning process, the agency began considering the value of discharge in Zone IIs as a form of reuse. Recharge into a Zone II was no longer an exclusion criteria, but Zone II locations and distance from production wells were still significant criteria in siting (see Appendix A, Map 1).

B. **Step 2**. Step 2 identified areas that were restricted due to their environmental significance and mapped locations of ACECs, the Coastal Plain Complex, vernal pools wetlands, flood zones, and areas of rare and endangered habitats (see Appendix A, Map 2).

C. **Step 3.** Step 3 mapped areas where groundwater was at depths less than 10 feet (see Appendix A, Map 3).

D. **Step 4.** Step 4 mapped hydraulic conductivity boundaries as defined in the 1992 Geraghty & Miller evaluation (see Appendix A, Map 4).

E. **Step 5.** In Step 5, areas within 1/2 mile of those areas identified in Step 3 that are mapped as having groundwater within 10 feet of the surface were identified. This criteria was established to address concerns related to groundwater mounding as a result of recharge and the potential impacts the mounding could have on structures such as basements, leachfields, and septic tanks.

At the end of Step 5, the process resulted in the identifications of three areas of Town that were most favorable for wastewater recharge. The three areas were designated as Area A, located south of the Mid-Cape Highway on the western side of Town; Area B, located along the Mid-Cape Highway in the vicinity of Cape Cod Community College; and Area C, north of the Mid-Cape Highway on the eastern boundary of the Town (see Appendix A, Map 5).

F. **Step 6.** In Step 6, coastal recharge areas were added to the mapping to determine which embayment would be the ultimate receiving water for the discharged effluent (see Appendix A, Map 6).

G. **Step 7.** In Step 7, distance from the existing wastewater treatment plant was indicated on the project mapping. Areas A, B, and C were prioritized with respect to their distance from the treatment plant. Area B was the top priority area, as it was closest to the treatment plant (see Appendix A, Map 7).

H. **Steps 8, 9, and 10.** In Steps 8, 9, and 10, Areas B, C, and A respectively, were evaluated in a more detailed manner. The sites were evaluated with respect to:

1. Parcel sizes.
2. Degree of existing development.
3. Location with respect to Zone IIs.
4. Type of ownership (public or private).
5. Soil characteristics.
6. Depth to groundwater.
7. Abutting land use.
8. Accessibility of site.
9. Proximity to pubic water supplies.
10. Proximity to conservation lands.
11. Which coastal recharge area.
12. Site topography.

The second round of screening concluded that Area B represented the most favorable area in Town for recharging treated wastewater (see Appendix A, Map 8). The area had the advantage of having minimal environmental concerns, appeared to have available sites, and was closest to the wastewater treatment plant. A possible disadvantage was the fact that the area was located on the Sandwich Moraine, where soil conditions are not as favorable for recharge than the outwash plain. This had to be accepted, however, in that the outwash plain is generally too densely developed for siting recharge facilities. Subsequent site-specific testing in Phase III would be employed to determine the suitability of the soils for recharge. A second possible disadvantage was that drainage was potentially to the north, which was considered to be less desirable than drainage to the south.

The Town concluded that detailed evaluations would be conducted at yet-to-be-identified candidate sites in the vicinity of Area B.

2.3 Candidate Site Selection

The next step in the site identification and screening task entailed identifying specific sites and parcels at which recharge was considered feasible, and assessing the availability of parcels. This step included selecting specific parcels, contacting owners, and establishing availability. At the end of this process, seven sites were identified as potential candidate sites. The sites and their initial evaluation are described below.

A. **Cape Cod Community College.** The college has a significant amount of undeveloped acreage available for use. The college is interested in being connected to the treatment plant, which could facilitate a cooperative venture between the Town and the college.

B. **McManus Site.** The McManus site is a Town-owned, 11-acre area southeast of the intersection of the Route 6 Mid-Cape Highway and Route 132. The site is advantageous because of the surrounding land use, but has the disadvantage of having rugged topography.

C. **Lorusso Property**. The Lorusso property is a privately owned 11-acre site that is a power line right-of-way, parallel to and just south of the Route 6 Mid-Cape Highway. The site had the advantages of compatible area land use, size, and a willing private owner; but the disadvantages of irregular topography and power lines and poles that limit development area.

D. **Cape Cod Aggregate Property**. The Cape Cod aggregate property had the benefit of size, availability, and proximity to an existing but unused force main. Initial inspection of the site revealed it was comprised largely of asphalt and stump fill material. As a result, the site was rejected from further consideration.

E. **Route 6 Corridor**. The median or edges of the Route 6 corridor in the Town of Barnstable were considered a possible candidate site. Early conversations with the Massachusetts Highway Department indicated reluctance on their part to allow discharge in the right-of-way. Provincetown had to purchase the right-of-way to use it for its effluent discharge facilities. Purchase of the long stretch of Route 6 in Barnstable was not regarded as a likely option, and consideration of use of the Route 6 corridor was suspended.

F. **Route 132 Corridor**. The Route 132 corridor between Route 6 and Hyannis was considered an option that was made more favorable by a planned reconstruction of that segment of road. However, because it was believed the road layout area did not represent a sufficient area for recharge, consideration was suspended.

G. **Barnstable Municipal Airport.** Although somewhat remote from Area B and previously removed from consideration because of some general environmental concerns, there was widespread belief within the regulatory community and the Town that the airport should still be considered for discharge. It has a large available area, early discussions with the airport indicated land could be made available, and it is in proximity to the treatment plant.

The initial screening of candidate sites resulted in the identification of four sites that would undergo a detailed site-specific characterization. Those remaining candidate sites included:

1. The McManus site.
2. Cape Cod Community College.
3. The Lorusso property.
4. The airport.

The locations of the sites are shown on Figure 2. The site characterization that was conducted at each of these sites is described in the next section.

SECTION 3 - SITE CHARACTERIZATION

3.1 Purpose Of Site Characterization

Although the candidate sites had been generally characterized through the screening and identification process, the hydrogeologic assessment had been based primarily on regional or sub-regional mapping. Soil types, stratigraphy, depth to water, and hydraulic properties can vary widely in a small area. Because of that, it was important to assess site-specific hydrogeologic properties of the site to verify that the site can accept the amount of water proposed for recharge at that site. There were two important parameters to evaluate to characterize the site: (1) the capacity of the site to allow vertical infiltration of water; and (2) the capacity of the aquifer beneath the site to convey water away from the recharge area. At sites where wick wells or injection wells are being considered, the vertical infiltration parameter is not a concern because effluent is conveyed directly into the aquifer. A related parameter is the depth to groundwater, which is important for determining the mounding impacts of a potential effluent discharge facility.

3.2 Field Investigation Tasks

Field investigation tasks at the four candidate sites included excavation of test pits, completion of percolation tests, completion of soil borings, installation of observation wells, completion of in-situ hydraulic conductivity tests (slug tests), and site surveys. In each case, each field investigation was preceded by a site reconnaissance trip and conversations with the landowners. The objectives of the site reconnaissance were to determine site conditions, determine possible discharge facility locations, identify areas for testing and assessing access to test locations by observing topography, presence of low wet areas, and density of trees on wooded land. At the meetings with site owners, the

Figure 2: Locations of candidate recharge sites in the Town of Barnstable

objectives of the study were reviewed and the proposed elements of the field work were discussed. Acceptable degrees of clearing or grading, if needed, were agreed upon.

Following site reconnaissance and meeting with the landowner, it was possible to develop a work plan for each investigation. In each case MADEP was informed of the identification of each site and that a field investigation was planned. MADEP was notified of the schedule in the event they wished to observe any of the proposed work.

The scope of work at each site was designed to be completed in an iterative fashion that would allow decision making as work progressed. If conditions suggested the site was not suitable at any point in the investigation, then subsequent tasks such as well installation in a boring would not be completed.

A. **McManus Site.** The McManus site has rugged topography that limited access and the owner did not permit any tree clearing. As a result of those limitations, one soil boring/observation well was installed. Six test pits were installed in accordance with MADEP protocols and were logged by a certified soil evaluator. Those test pit observations could subsequently be used for the groundwater discharge permit application, although it was known it would be necessary to complete additional test pits in the future, should a decision be made to permit the site.

The observation well revealed that the subsurface at the site was comprised of fairly uniform fine to medium sand with traces of silt and gravel. The sand was very tightly packed. Groundwater was encountered at a depth of 58 feet, and a low permeability layer was encountered at 84 feet.

Multiple slug tests were performed in the observation well to estimate hydraulic conductivity. The slug tests yielded a result of approximately 1 foot per day. This was a lower rate than anticipated based on USGS and other published regional information and the nature of the material penetrated. Municipal supply wells located approximately 3,000 feet southeast of the site yield approximately 700 gpm, suggesting a higher hydraulic conductivity. Also, the generally clean sands present in the well would suggest a higher hydraulic conductivity. USGS has mapped this area to have a hydraulic

conductivity of approximately 200 feet per day. The low results could be attributed to the tight nature of the sands observed or the inherent inaccuracies of slug tests.

Test pits were advanced to 7 or 8 feet and revealed sandy loam grading to fine to medium sand. Percolation test rates ranged from 1.3 to 4.3 minutes per inch, under the 5 minutes per inch specified by MADEP for a loading rate of 5.0 gpd/sq. ft.

The investigation concluded that the McManus site could be a potential discharge site. Advantages included proximity to the treatment plant; suitable surrounding land use; good percolation rates; uniform, clean sand; and deep groundwater. Disadvantages included irregular topography and a potentially low hydraulic conductivity. The potentially low hydraulic conductivity is not necessarily a deterrent to development because of the significant depth to groundwater, which would limit adverse impacts of mounding. Based on the available area, the capacity of the site was estimated at approximately 1,600,000 gpd. Based on the results of the site investigation, the Town retained the McManus site as a candidate location for discharge.

B. **Cape Cod Community College.** The investigation at the college focused on two separate areas -- an athletic field and a wooded area. One observation well and one test pit were used to characterize the athletic field, and two observation wells and two test pits were used to characterize the wooded area. Following the original site reconnaissance and meeting with college personnel, it was determined the characterization of the wooded area would be accomplished with wells and test pits along the edge of the wooded area in order to avoid clearing trees or grading a road to the interior of the site.

The athletic field is approximately 5 acres and the wooded area is approximately 17 acres. The advantages of the field are that it is graded flat and is already open. The disadvantage is that it is only suitable for a subsurface system, which has less capacity per available area. The advantage of the wooded area is its size, and the disadvantages are that it is wooded and has irregular topography that would require additional grading.

Both the test pit and soil boring in the field revealed there are a number of large boulders in the subsurface. The boring location had to be moved twice to find a

location suitable for drilling. The presence of the boulders would complicate construction and could potentially impact the effectiveness of the site for recharge, so further consideration of the field was deferred.

The observation wells and test pits adjacent to the wooded area provided results that indicated the area could be suitable for discharge. Fill material and boulders were present in one of the test pits near the woods, so a percolation test was only completed in one of the two test pits. A percolation rate of 0.67 minutes per inch indicated the suitability of the area. The observation wells adjacent to the wooded area were advanced to depths of 84 and 96 feet. Fine to coarse sand was observed in both wells over their entire depth, and groundwater was encountered between 65 and 70 feet.

Slug testing indicated a hydraulic conductivity of approximately 100 feet per day, a reasonable value for the aquifer materials observed. Based on an estimated recharge of 1 mgd, a mound of approximately 12 feet was calculated. With groundwater being 65 to 70 feet deep, that degree of mounding did not represent an adverse impact.

The wooded area of the college was retained as a viable discharge site. The site has the advantage of size, with approximately 8 acres of application area available, allowing for the discharge of approximately 1.7 mgd using sand beds. If subsurface trenches are utilized, the capacity is approximately 1 mgd. One disadvantage associated with the site is the rolling topography, which would require additional site preparation work.

C. **Lorusso Property.** The Lorusso property is owned by a local sand and gravel supplier. It is comprised of 11 acres in multiple parcels and is situated along a power line right-of-way immediately south of Route 6. The site had the advantage of size and suitable adjacent land use, but the disadvantages include irregular topography and power line poles that would limit the extent of discharge facilities.

The site was investigated with three observation wells, slug tests, five test pits, and four percolation tests. The observation wells indicated the subsurface is comprised primarily of fine sand. At a depth of approximately 40 feet in two of the borings and 70 feet in the third boring, the fine sands graded to silt. Groundwater was

encountered between 60 and 65 feet. Slug testing indicated a hydraulic conductivity of approximately 50 feet per day. Earlier modeling in this area had used a similar hydraulic conductivity, but more recent modeling efforts by the USGS assumed a higher rate (150 feet per day). For mounding calculations, a conservative conductivity of 50 feet per day was used. Based on a discharge rate of approximately one million gallons per day, a mound height of 12 feet was calculated.

Because of the site's location on the crest of the Sandwich Moraine, groundwater flow direction could conceivably be to the north or south especially after mounding effects are considered. The site is in the Zone II of a well located approximately 2,000 feet to the northwest, but travel time to that well was calculated to be approximately five years. Travel time is a function of hydraulic conductivity and hydraulic gradient.

The test pits revealed uniform fine sand in the subsurface across the site, with the exception of the northeastern test pit, which had a silt layer present at a depth of about 6 feet. A percolation test was not completed in that test pit. In the other test pits, percolation rates of under 2 minutes per inch to 4.6 minutes per inch were recorded, indicating the suitability of the site.

It was determined that the Lorusso property would remain under consideration for discharge.

D. **Airport.** The airport is a roughly triangular piece of property, opening up to the northwest and northeast. The airport property includes 418 acres with a large area of flat, open land bordering the runways. Advantages of the airport include the expanses of open, flat land and proximity to the treatment plant. Disadvantages include proximity to endangered wildlife, proximity of production wells, shallow groundwater (15 to 20 feet), and construction limitations resulting from being on airport property. Specifically, there can be no construction within 150 feet of the runways and no vertical obstructions within 500 feet of the runways, meaning that subsurface leaching systems would have to be utilized.

Three areas of the airport were investigated: the northwest corner, the northeast corner and the east side of the southern point of the airport. Each area was investigated with one observation well

and three test pits. One percolation test was completed in each area. Slug tests were attempted, but were determined to not be representative of the soil conditions present, so hydraulic conductivity values used in USGS mapping efforts were used for groundwater travel time and mounding calculations. Test pits and percolation tests revealed the presence of medium to coarse sand and percolation rates of approximately 2 minutes per inch, generally good conditions for recharge.

The soil borings revealed the subsurface was comprised of medium to coarse sand and groundwater was at a depth of approximately 20 feet. Being in the outwash plain, rather than on the moraine, the airport had the most favorable soil conditions; however, the location was also accompanied by shallower groundwater. Based on a discharge rate of 1 mgd, a mound of approximately 13 feet was calculated, which results in the water table potentially rising to within 7 feet of the surface. Mottling observed in test pits further suggested that seasonal high groundwater could be higher than levels observed during the field investigation, which could limit recharge rates. Buildings or septic systems proximal to the airport could potentially be impacted.

Groundwater flow rates were also considered, given the proximity of the candidate discharge sites to production wells. However, flow rate calculations indicated that discharge sites were probably beyond the two-year travel time from the production wells.

Although the airport had many advantages and was not removed from further consideration, its priority was lowered because of concerns related to water table elevation and groundwater mounding.

3.3 USGS Modeling

Concurrent with the Town completing its site investigations, Barnstable County, through the Cape Cod Commission, entered into an agreement with the USGS to provide groundwater modeling in support of the Town's wastewater planning efforts. The timing of the Barnstable project and the agreement with USGS allowed Barnstable to be the first town to take advantage of this service.

USGS has completed several versions of groundwater models across Cape Cod over the past several years. The models have recently been upgraded and revised

related to water supply evaluations and to support the Massachusetts Estuaries Project. Separate models have been completed for the following groundwater systems on the Cape:

1. The Sagamore Lens which extends from Falmouth to Barnstable.

2. The Monomoy Lens that extends eastward to Chatham.

3. The multiple smaller lenses on the Outer Cape extending from Eastham to Provincetown.

The Town of Barnstable falls into the Sagamore Lens model. The basic model reflects groundwater contours as a function of pumping from production wells and the recharge from the Barnstable treatment plant in addition to natural recharge and discharge and return flow from septic systems.

The existing model served as a useful tool for further evaluating the effects of recharge at the various candidate sites. The USGS was able to modify their model by adding the proposed recharge at the various candidate sites. After the proposed recharge was added, the simulations provided information related to mounding, flow direction, travel time, and discharge to surface waters. Numerous possible recharge scenarios were completed by USGS at request of the Town, including:

Scenario 1 - 1 mgd at WPCF; 0.5 mgd at the McManus site, 0.5 mgd at Cape Cod Community College

Scenario 2 - 1 mgd at WPCF; 1 mgd at the McManus site

Scenario 3 - 1 mgd at WPCF; 1 mgd at Cape Cod Community College

A number of other potential scenarios were also modeled. The output for the model runs (Appendix B) provided information related to flow rates and directions. Flow rate and direction was indicated through the use of particle track lines. A specific quantity of water was recharged at each recharge site and a specific number of "particles" was assigned to the recharge cells that represented the flow of water from that location. The number of particles can therefore represent the quantity of water flowing from the recharge site, and the track of the particles represents the flow direction. The particles can also be used to represent

mass of conservative solutes, such as nitrogen, that is flowing from the discharge sites. Additionally, the tracks of the particles are color coded to represent distance traveled after various time intervals (1 to 5 years, 5 to 10 years, 10 to 50 years, and 50 to 100 years).

Some of the general observations from the simulations include:

1. Groundwater elevation at the treatment plant lowered in response to distributing some of that flow to remote sites.

2. Groundwater mounds of 4 to 8 feet formed at the new remote discharge sites depending on the distribution of flow.

3. In Scenario A, all flow from the college was toward Barnstable Harbor.

4. In Scenario B, most of the flow from the remote sites was toward Barnstable Harbor, with minor flows to proximal public supply wells and some flow to the south toward Lake Wequaquet.

The modeling provided information that assisted in evaluating the various remote sites. Issues identified in reviewing the model outputs included nutrient flow to Barnstable Harbor and Lake Wequaquet, and treated effluent flow toward production wells. The general conclusion of the modeling effort was that issues warranting consideration were identified related to every scenario, but none were perceived as being so significant as to prevent further evaluation of any of the scenarios.

SECTION 4 - CONCEPTUAL DESIGN AND COST EVALUATIONS

4.1 DISCHARGE TECHNOLOGY SCREENING

After the four candidate sites were screened, evaluated, and determined to warrant final characterization, discharge technologies were evaluated for suitability at each site. The various technologies described in Part 1 of this document were evaluated for suitability at each of the four candidate sites. RIBs, subsurface leaching, and spray irrigation were considered. Injection wells and wick wells were rejected because they are generally unproven technologies in this area and because of regulatory resistance. Each of

the technologies was considered at each of the four sites. The results of that evaluation are summarized below.

A. **McManus Site (Site B).** At this site, RIBs and subsurface infiltration were identified as appropriate technologies. Spray irrigation was identified as not appropriate due to the visual and misting impacts adjacent to Route 6.

B. **Airport Site (Site C).** At this site, subsurface infiltration was identified as an appropriate technology. RIBs and spray irrigation were identified as inappropriate because they could produce areas of standing water which could attract birds and be a hazard to air traffic. Also, the sand bed technology would utilize aboveground structures (berms), which are not allowed in close proximity to the runway.

C. **Cape Cod Community College Site (Site D).** At this site, RIBs and subsurface infiltration were identified as appropriate technologies. Spray irrigation was identified as not appropriate due to the visual and misting impacts adjacent to Route 6, the college center, and the interchange.

D. **Lorusso Site (Site E).** At this site, RIBs and spray irrigation were identified as appropriate technologies. Subsurface infiltration was identified as not appropriate because its lower hydraulic application rate in combination with the small site would result in a small discharge capacity.

Based on this evaluation, the following seven scenarios were developed for further evaluation:

B1: McManus site with RIBs
B2: McManus site with subsurface infiltration
C2: Municipal Airport site with subsurface infiltration
D1: Cape Cod Community College site with RIBs
D2: Cape Cod Community College site with subsurface infiltration
E1: Lorusso site with RIBs
E3: Lorusso site with spray irrigation

4.2 Conceptual Design

After potential discharge technologies were identified for each site, a conceptual design was completed which included a layout defining the actual recharge area

and associated capacity of the site with each selected discharge technology. The resultant capacity was one of the final evaluation criteria for the site.

Each alternative conceptual design was developed as described below. Conceptual layout sketches are provided in Appendix C.

A. **B1 - The McManus Site with RIBs.** Approximately 8 acres would be available for effluent application and approximately 1.6 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include the installation of a 12-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

B. **B2 - The McManus Site with Subsurface Infiltration.** Approximately 9 acres would be available for effluent application and approximately 0.7 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities and effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

C. **C2 - The Municipal Airport Site With Subsurface Infiltration.** Approximately 28 acres would be available for effluent application and approximately 2.3 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities, phosphorus removal facilities, and effluent pumps. Improvements along the route would include the installation of a 14-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

D. **D1 - The Cape Cod Community College Site With RIBs.** Approximately 8 acres would be available for effluent

application and approximately 1.7 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

E. **D2 - The Cape Cod Community College Site With Subsurface Infiltration.** Approximately 15 acres would be available for effluent application and approximately 1.1 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include new filtration facilities and effluent pumps. Improvements along the route would include the installation of a 10-inch force main with associated structures. Improvements at the site would include a receiving wet well, dry well with pumps, grading, piping, valves, and infiltration trench construction.

F. **E1 - The Lorusso Site with Site RIBs.** Approximately 2.3 acres would be available for effluent application and approximately 0.5 mgd could be applied. Development of this design would require infrastructure improvements at the WPCF, along the route, and at the site. Improvements at the WPCF would include installation of primary and standby effluent pumps. Improvements along the route would include the installation of a 8-inch force main with associated structures. Improvements at the site would include grading, piping, and sand bed construction.

G. **E3 - The Lorusso Site With Spray Irrigation.** Approximately 5.0 acres would be available for effluent application and approximately 0.04 mgd could be applied. Based on the limited application volumes, this scenario was not been developed.

Following the conceptual design and determination of the various engineering requirements for each site, costs were developed for each site. A final site ranking was developed that included such criteria as size, capacity, topography, depth to water, soil type, adjacent land use, proximity to sensitive receptors and cost. Tables 4-1 and 4-2 summarize these factors.

TABLE 4-1

SUMMARY OF EFFLUENT DISCHARGE TECHNOLOGIES
Effluent Discharge and Reuse
Guidance Document and Case Study Project
Barnstable County Wastewater Implementation Committee and Town of Barnstable, MA

ALTERNATIVE	REGULATORY REQUIREMENTS	EFFLUENT QUALITY	MAINTENANCE REQUIREMENTS AND COMPLEXITY OF OPERATION	FLEXIBILITY	ENERGY USE
Rapid Infiltration Beds	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Effluent is already treated and sand beds provide some additional treatment.	Effluent discharge is reliable throughout the year and easy to maintain.	Flexibility is possible with multiple beds.	Lowest energy requirements due to no need to repump the effluent at the sand beds.
Subsurface Infiltration	Disinfection is not required prior to discharge, unless required to meet the Interim Guidelines for Reclaimed Water Use.	Effluent is already treated and infiltration facilities provide additional treatment. Effluent should be filtered before discharge.	Repair of the beds would be difficult because they are subsurface	Moderate depending on construction of dosing equipment and distribution piping.	Moderate due to effluent dosing pumps.
Spray Irrigation	Permitting and monitoring of effluent discharges and design requirements. Disinfection may be required by MADEP.	Spray irrigation provides further uptake of nitrogen in the effluent.	Moderate maintenance to maintain piping. Spray irrigation cannot be used in freezing weather.	Must have redundant back-up facilities for winter discharge.	Moderate due to repumping requirements.
Ocean Outfall	The Massachusetts Ocean Sanctuaries Act prohibits discharge of municipal wastewater into an ocean sanctuary. An NPDES permit required.	Disinfection may be required for the outfall.	Maintenance similar to a large force main	Minimal, unless land disposal remains for some backup discharge.	Moderate due to pumping requirements
Deep Well Injection	Permitting and monitoring of effluent discharges and design requirements. MADEP is not supportive of this technology.	Effluent must be well treated (filtered and chlorinated) before discharge.	Uncertain reliability due to few operating installations and increased maintenance due to the potential of plugging of injection point with solids.	Installation of multiple wells would allow individual wells to rest or be repaired.	Moderate due to repumping requirements.

TABLE 4-1 (continued)

ALTERNATIVE	REGULATORY REQUIREMENTS	EFFLUENT QUALITY	MAINTENANCE REQUIREMENTS AND COMPLEXITY OF OPERATION	FLEXIBILITY	ENERGY USE
Wick Wells	Permitting and monitoring of effluent discharges and design requirements. MADEP regards this as an innovative technology.	Effluent must be well treated (filtered and chlorinated) before discharge.	Uncertain reliability due to few operating installations and increased maintenance due to the potential of plugging of injection point with solids.	Installation of multiple wells would allow individual wells to rest or be repaired.	Moderate due to repumping requirements.
Wetland Restoration	Possible extensive wetland permitting depending on the type of restoration. Permitting and monitoring of effluent discharges and design requirements. MADEP regards this as an innovative technology.	Effluent must be well treated (phosphorus removal in addition to standard nitrogen removal, and disinfected before discharge)	Very low maintenance requirements and low operations complexity.	Minimal operations control. Flexibility would be provided with variable surface water level controls in the abandoned bog.	Moderate due to repumping requirements.

ALTERNATIVE	LAND REQUIREMENTS	POTENTIAL FOR AIR EMISSIONS	PUBLIC ACCEPTANCE	RELATIVE CAPITAL COSTS	RELATIVE O&M COSTS	SELECTED FOR DETAILED EVALUATION
Rapid Infiltration Beds	Moderate at large wastewater flows when compared to subsurface leaching.	Effluent is treated to a high level and odors would be minimal.	Potential for low acceptance from residents who are impacted by bed siting and construction.	Relatively low due low land area and easier construction.	Low due to low energy requirements and minimal maintenance.	Yes; the technology is simple and reliable. O&M requirements are minimal.
Subsurface Infiltration	Relatively high. Land surface above the infiltration system can be used for other purposes	Minimal.	Acceptance should be high due to minimal visual impacts and potential reuse of land area.	Relatively high due to highest land area and extensive piping.	High due to pumping requirements and potential high repair/cleaning costs.	Yes; technology is reliable and provides secondary use of discharge area.

TABLE 4-1 (continued)

ALTERNATIVE	LAND REQUIREMENTS	POTENTIAL FOR AIR EMISSIONS	PUBLIC ACCEPTANCE	RELATIVE CAPITAL COSTS	RELATIVE O&M COSTS	SELECTED FOR DETAILED EVALUATION
Spray Irrigation	Relatively high. Land above system can be can be used for other purposes when spray irrigation is turned off.	Minimal.	The public will want to see recycling of the effluent though they may be concerned about possible health threats.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to maintenance and pumping requirements.	Yes; it provides additional nitrogen uptake and reuse of the effluent.
Ocean Outfall	Minimal.	Minimal.	Low. Based on the opposition to the Deer Island outfall and the Ocean Sanctuaries Act.	Relatively high due to land area, extensive permitting pumping requirements.	Moderate due to pumping requirements	Yes, as a last alternative if all other land disposal alternatives are not sufficient to meet the Town's need.
Deep Well Injection	Relatively low compared to sand infiltration beds and subsurface leaching.	Minimal.	Land area requirements and visual impacts are minimal.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	No; MADEP is resistant to support the technology due to the need to chlorinate the effluent
Wick Wells	Relatively low compared to sand infiltration beds and subsurface leaching.	Minimal.	Land area requirements and visual impacts are minimal.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	Yes, MADEP has recently permitted a wick facility. Low land area is a benefit, however, MADEP is currently requiring 100% capacity reserve area for conventional system.
Wetland Restoration	Would make use of an existing extensive land area. The restoration efforts would occur in specific flow control and infiltration areas.	Minimal.	Could be favorable due to understanding that the technology/ concept is a restoration effort and the project could restore proper hydraulic balance to the watershed.	Relatively low due to minimal excavation, and minimal need to reshape the land.	Moderate due to pumping requirements. And maintenance needs.	Yes. There is much interest at MADEP with this concept to take an integrated approach to watershed management. This could be cost effective and provide secondary benefits.

Table from Task 8 Report, *"Candidate Site Evaluation and Comparison, Stearns & Wheler, 2004."*
Capital costs are based on an Engineering News-Record (ENR) Index of 6,800 for 2003 costs.
Present-worth cost based on n = 20, I = 7.625%, P/A = 10.1.
All costs rounded to two significant digits.

4.3 Next Steps And Ongoing Efforts

The Town is proceeding with the legal considerations and decision making needed to move forward with the two highest-ranked sites: the McManus site and Cape Cod Community College. These sites have constraints related to state ownership, conservation restrictions, and questions of infiltration capacity due to their location in a moraine area of Cape Cod. The Town has begun a hydraulic loading test at the McManus site to develop better infiltration capacity information. At the same time, the Town is exploring possible agreements with the involved state agencies.

As of early 2005, the Town is evaluating an additional effluent discharge/reuse concept that would utilize the following components:

1. Installation of an effluent supply pipe through the central portion of Hyannis that would facilitate lawn irrigation at Town properties.

2. Discharge upgradient of the abandoned cranberry bog located near the border of Barnstable and Yarmouth to remediate groundwater withdrawals in that area.

3. Additional treatment at the Hyannis WPCF to provide additional water purification and allow the effluent to be used for irrigation on public parks and discharge at the impacted wetland (abandoned cranberry bog).

This concept is very innovative and would be coupled with a wetland restoration at the cranberry bog. The feasilbity study for this scenario is planned to be completed in June 2005.

4.4 Conclusions

The siting of new effluent discharge and reuse facilities has been a long and detailed process in Barnstable. The Town has proceeded proactively and carefully to site these facilities in a cost-effective manner. We have worked closely with the regulatory agencies to consider innovative solutions and find a management scenario that is cost effective. The Town has considered all alternatives.

The final recommendations of this siting project have not yet been determined.

They must await the decision making process that has to weigh the politics with the solid science, engineering, and cost estimating we have completed to date.

The Town appreciates the opportunity to share this experience with other towns on Cape Cod and with other municipalities off Cape. The Town plans to identify the final recommendations on the Town website as part of the Comprehensive Wastewater Management Plan.

SECTION 1 – INTRODUCTION

1.1 PURPOSE OF REPORT

The Town of Barnstable is undertaking comprehensive Wastewater Management Planning to develop strategies for collecting, treating and disposing of wastewater. A key element of that planning process is identifying a site in the Town where treated wastewater can be applied to recharge groundwater. This report describes the testing that was completed at one candidate site to determine its suitability for receiving and infiltrating treated wastewater.

1.2 BACKGROUND

In the course of completing comprehensive wastewater management planning, the Town of Barnstable determined that additional wastewater collection and treatment at the existing water pollution control facility (WPCF) was an appropriate remedy to water quality concerns in the Town.

To accommodate an increase in treated effluent from the treatment plant, the Town has been seeking remote locations for the recharge of highly treated effluent. The Town undertook an extensive screening process to identify areas of Town that would be most suitable for wastewater recharge. They then identified four specific sites that were considered favorable for recharge. Preliminary investigations, including completion of soils borings, observation wells, test pits, and percolation tests, were completed at each of the four sites. At the culmination of that testing, the Town determined that the site referred to as the McManus site, located just southeast of Exit 6 on Route 6 (see Figure 1, Site Location Map) would be the Town's priority candidate site. This decision was based on a number of factors, including location, distance to the WPCF, surrounding land use, proximity of sensitive receptors, size, and hydrogeologic properties.

1.3 PRELIMINARY SITE CHARACTERIZATION

The McManus site is comprised of four separate parcels, all owned by the Town. The site is trapezoidal in shape, occupies approximately 28 acres, and is comprised of wooded, rolling terrain. The preliminary investigation completed in the spring of 2003 indicated generally favorable conditions for treated wastewater recharge. Test pits revealed the surficial material was comprised of fine to medium sand. Percolation test rates were all under 5 minutes per inch. The soil boring indicated fine to medium, tightly packed sands to a depth of 85 feet.

Because the site is located on the Sandwich Moraine, soil types can be quite variable and the presence of clay layers or boulders is a possibility, but the preliminary evaluation revealed conditions that suggested the site was generally acceptable.

1.4 RECOMMENDATIONS BASED ON PRELIMINARY SITE CHARACTERIZATION

After the initial screening process and the preliminary site evaluations, the Town selected the McManus site as the priority candidate site. However, because the site is on the moraine where geology can be variable, and because the subsurface, although comprised of fine to medium sand, was tightly compacted, the Town determined that additional testing was warranted to verify the site's hydrogeologic suitability. Larger-scale loading tests were proposed to further evaluate the infiltration capacity of the site soils. The proposed loading test would evaluate the site soils' infiltration capacity using thousands of gallons of water rather than a few gallons of water, as are used for percolation tests, plus the loading tests would allow an evaluation of potential water table mounding impacts.

SECTION 2 - FIELD INVESTIGATION

2.1 LOADING TESTS

Loading tests are essentially large-scale percolation tests. They are accomplished by applying large quantities of water to basins with a specific surface area to allow the calculation of an infiltration rate in minutes per inch and in gallons per day per square foot. The general protocol for completing loading tests is described in the USEPA *Process Design Manual–Land Treatment of Municipal Wastewater (1981)*. A work plan was developed describing the proposed loading test and was submitted to the Massachusetts Department of Environmental Protection (MADEP) for review and approval.

2.2 TEST PREPARATION

Six locations were chosen as test sites. The test sites were spaced throughout the entire McManus site to obtain a comprehensive idea of the site's potential for infiltrating treated effluent. Figure 2 is a site map showing the location of the test basins on the site. One 10-foot diameter basin and two observation wells were installed at each test site (except for Basin 2, where only one well was installed). The basins served as the infiltration sites for the loading tests and the observation wells were installed for monitoring the water table response to the infiltration tests.

Test site preparation included sufficient clearing and grading to allow access to drilling equipment and construction equipment to install the test basins. The drilling contractor and the excavation/construction contractor worked concurrently to construct the wells and basins. The driller installed two wells at each basin, one adjacent to the test basin and one 50 feet away from the basin. At Test Basin 1, the original well installed in the 2003 preliminary investigation served as one of the two wells. At Test Basin 2, a significant clay layer was encountered in the interval from 42 to 82 feet in one of the borings. No well was installed in that boring, and the test at Test Basin 2 was conducted with only the immediately adjacent observation well. The soil conditions were observed and noted during the drilling process. Boring logs are provided in Appendix A. Drilling continued until groundwater was reached and then continued approximately 10 feet below the water table. Once the final depth was reached, observation wells were installed in each boring. Wells were constructed with 2-inch PVC pipe, including 10 feet of

PVC screen at the bottom of the well. Wells were finished with a cast iron protective casing and a locking cap.

Basin installation was completed after the wells were installed. The basin sites were excavated to a depth sufficient to clear top soil and roots. The soils below the top soil were primarily medium and coarse sands. The contractor provided prefabricated 10-foot diameter, 30-inch tall, 3/16-inch thick, aluminum "rings" which served as the walls of the basin. The rings were put in place and pushed into the soils approximately 6 inches below the excavated depth. This served to seal the basin walls into the ground to promote the vertical flow of water out of the basins rather than lateral flow. The basin walls were secured in place by backfilling the outside of the walls up to the original grade. A schematic of a completed test basin is shown in Figure 3. Photographs of basin construction are provided in Appendix B.

A 21,000-gallon storage tank was brought to the site and was supplied by a Barnstable Fire District fire hydrant located a few hundred feet north of the storage tank. A pump and approximately 3,500 feet of pipe and hose were provided to supply water for the testing. A valve for controlling flow was located at each test basin.

Pressure transducers were placed in each of the wells located immediately adjacent to the basins four days before the testing began. The transducers were installed early to provide background water table levels before any loading took place. The transducers were left in place for the duration of the loading tests to observe any effects the loading tests had on the groundwater levels.

2.3 CONSTANT HEAD AND FALLING HEAD TESTS

A series of tests were conducted at the basins over an eight-day period. Appendix B includes selected photographs taken during the testing. There was adequate water supply to test two basins at a time and each round of tests took three days. The testing was completed on the schedule displayed on Table 1.

The basin testing included three phases, as indicated on the schedule: saturation, constant head testing, and falling head testing. Each phase is described below.

A. **Saturation.** The soils at each basin were saturated before testing began. This was done by supplying water to the basin for a 24-hour period. Flow into each basin was sustained at a rate that would keep a generally constant level of water in the test basin, although the exact level was not a factor. As saturation progressed, the infiltration rate of the underlying soils declined. By the end of the day, it was possible to adjust the flow into the basins to a rate that would keep water in the basins overnight without flooding them.

B. **Constant Head Test.** The constant head tests were started after the basins had been saturated for 24 hours. The constant head test was performed by noting the water level in the basin and supplying enough flow to maintain this level over the course of an eight hour test period. In the early stages of the test, the flow rate had to be adjusted periodically to keep the water level in the basin constant. The water level was noted, the flow rate was measured, and the observation well water levels were measured throughout the testing. In the constant head tests, the infiltration capacity is measured in gallons per minute (gpm) as water is added to the 10-foot infiltration basin at the same rate that the water infiltrates out of the basin. Flow rate was measured at the spigots using containers of known volume and a stop watch. By dividing the amount of flow in a day by the square foot area of the basin, an infiltration capacity in gallons per day per square foot is calculated.

At the end of the day of constant head testing, the basins were again supplied with a constant flow overnight to maintain saturated conditions.

C. **Falling Head Test.** The falling head tests were started the day after the constant head tests. These tests were performed by filling the basin to a specific level and then cutting off the water supply and observing the rate at which the water level in the basin dropped. The falling head tests were repeated three times by refilling the basin after the water level had dropped a minimum of 6 inches for each test. In the falling head tests, infiltration is measured in inches per hour. This result is converted to cubic feet per hour and subsequently to gallons per day per square foot. Water levels in the monitoring wells were observed throughout the falling head tests.

SECTION 3 - FINDINGS AND CONCLUSIONS

3.1 SUBSURFACE CONDITIONS

Additional information regarding subsurface conditions at the site was obtained through the installation of the 11 new soil borings. Conditions are generally homogeneous across the site. The entire section penetrated is comprised primarily of fine to coarse sand. A layer of gravel and evidence of cobbles were encountered in many of the borings at a depth of about 15 feet. Isolated silt layers were also encountered in some of the borings. In Boring 2B, a significant stiff gray silt layer was encountered at a depth of 42 feet. The silt layer was penetrated to a depth of 82 feet, but the bottom of the silt layer was never encountered. The silt layer was limited to the northeast corner of the site and was not encountered in the other borings, not even the other boring installed at Test Basin 2. Because the silt layer did not extend further into the McManus site, it was determined that it would not adversely impact the performance of the site, as a whole. A well was not installed in the 2B boring, but a well was installed in the 2A boring and a loading test was completed at Test Basin 2.

Also in the 2A boring, boulders or cobbles had a more significant presence in the 0-20 foot section than in other borings. In several other borings, cobbles were detected in the 15 to 20 foot interval, but did not appear to have a significant impact on the overall character of the stratigraphic profile. However, in boring 2A, in almost the entire section from the surface to 20 feet, boulders or cobbles were present. As part of final design of the site facility, this area of the site will be further characterized to verify suitability.

A silt layer was also encountered in Boring 5A in the interval between 51 and 60 feet below grade. Because a significant silt layer was not encountered in the other borings, it is unlikely that the silt layers encountered in Borings 2B and 5A were connected.

The surface elevations at the various test sites range from 61 to 90 feet. Depth to groundwater at the site ranges between 33 to 50 feet, depending on the surface elevation; and groundwater at the site is found in the elevation interval between 34.5 and 36 feet. Figure 4 illustrates two profiles across the site, based on surveyed elevations and groundwater depth measurements. Based on data obtained from the on-site wells, groundwater flows to the northeast. This conclusion is consistent with Town's town-wide water table mapping.

Overall, the subsurface conditions are generally homogeneous, comprised of fine to coarse sand with lenses of gravel or cobbles and silt. The predominance of the sand suggests suitable conditions for infiltration of treated wastewater.

3.2 CONSTANT HEAD TEST RESULTS

The first set of testing at each basin was constant head testing. As described above, the constant head testing entailed adding water to the basins at the same rate that water drained out of the basin. As expected, from the time saturation was initiated to the time the constant head tests were initiated, the infiltration rate decreased considerably as the soils became more saturated. However, during the constant head tests, the infiltration rates remained generally constant, with the exception of Basin 4, which had variable, but much faster infiltration rates. The infiltration rates for the six infiltration tests are illustrated on Figure 5.

The raw data from the constant head tests is presented on Table 2 and summarized on Table 3. With the exception of Basin 4, which accepted a flow rate of 10 to 17 gpm, the basins generally accepted a flow of approximately 5 gpm. Some were closer to 4 gpm and others were closer to 6 gpm, but for general discussion, a rate of 5 gpm is a reasonable generalization. Five gpm equates to 7,200 gallons per day (gpd). The discharge of 7,200 gpd in a 10-foot diameter basin (surface area 78 sq. ft.) equates to 92 gpd/sq ft. If, for the purposes of design, the most conservative recharge rate of 4 gpm is used to calculate infiltration rate, the calculated rate is 74 gpd/sq. ft.

USEPA protocols for conducting loading tests suggest that, although loading tests are probably the most accurate means of estimating loading rate, loading tests have a greater horizontal flow component than full-scale installations; therefore, loading tests overestimate full-scale capacity. Therefore, USEPA recommends design rates that are only 10 to 15 percent of observed rates in loading tests. The loading tests suggest an infiltration rate of approximately 74 gpd/sq ft, hence a design loading rate of up to 7 gpd/sq ft can be considered reasonable. MADEP establishes a maximum design loading rate of 5 gpd/sq ft, but allows proponents to make a demonstration for a greater loading rate, once full-scale facilities are constructed and operational.

Based on the results of the constant head testing, which indicated a infiltration rate of at least 74 gpd/sq ft, a design loading rate of up to 7 gpd/sq ft is reasonable. Hence, the MADEP-

recommended rate of 5 gpd/sq ft for rapid infiltration beds or 3.0 gpd/sq ft for leaching trenches is appropriate.

3.3 FALLING HEAD TEST RESULTS

To supplement the constant head test results, falling head tests were performed in each of the basins after the constant head tests were completed. Between the tests, water was continuously added to the basins to retain the saturated soil conditions.

To complete the falling head tests, basins were filled to a specific measured mark. The water supply was then turned off and the rate at which the water level in the basin dropped was recorded. The falling head tests were repeated three times in each basin, with the basin being refilled at the beginning of each test run. The results of the falling head tests are presented on Tables 4-1 through 4-6. Infiltration rate is presented in three different units on the tables: minutes per inch, inches per hour, and gallons per day per square foot (gpd/sq ft). Infiltration rates in minutes per inch (the units used in MADEP guidance) are illustrated on Figures 6 through 11. Infiltration rates in gpd/sq ft for all of the tests are summarized on Figure 12. The average infiltration rates in gpd/sq ft for each of the basins were 90 gpd/sq ft, 59 gpd/sq ft, 51 gpd/sq ft, 137gpd/sq ft 74 gpd/sq ft and 82 gpd/sq ft, respectively. The highest average was at Basin 4 (137 gpd/sq ft) and the lowest average was at Basin 3 (51 gpd/sq ft). The average result was 82 gpd/sq ft, but this average is affected by the results from Basin 4, which cannot be considered representative of site-wide conditions because of the anomalously high infiltration rates at that site. To be conservative, if the lowest average infiltration rate of 51 gpd/sq foot is used as the basis on design, and the EPA criteria of using 10 percent of the infiltration test rate is applied, a design loading rate of 5 gpd/sq ft is appropriate. This specified design loading rate is based on a number of conservative considerations. First, the USEPA's 10 percent factor has been applied, and second, it is based on the lowest average value across the site (51 gpd/sq ft) rather than the average rate (82 gpd/sq foot), which is more likely representative of overall site conditions.

3.4 MOUNDING IMPACTS

Two observation wells were installed at each basin with the exception of Basin 2, where subsurface conditions did not warrant the installation of a second well. Recording pressure transducers were placed in each of the "A" wells (i.e., the wells immediately adjacent to the

basins) four days prior to the startup of the testing to record background conditions. The transducers recorded water level in the wells every 15 minutes and were left in place throughout the tests and for a period of four days after testing was completed. Additionally, water levels were measured in the B wells during the course of the testing at the respective basin.

Water level data is depicted graphically on Figures 13 through 18. Figure 19 is a compilation of the six data sets so that the fluctuations in water levels in the six wells can be compared.

Although there are fluctuations in the water levels in the wells, they all track very similarly, independent of the fact that the testing took place in the wells during different times during the 10-day test period. The three-day period, during which the testing was undertaken at each well (one day saturation, one day constant head test, one day falling head test, with continuous saturation occurring during the night), is depicted on the graphs by the yellow block. The loading testing did not appear to have any noticeable impact on the water table at the site of each basin. The fluctuations observed on the graphs occurred at the same times in each of the six wells independent of whether the testing was occurring.

There was no precipitation during the testing or during the week prior to the testing, which was initiated on June 6. Between May 22 and May 29, there were eight days of rain. Daily totals ranged from 0.01 to 0.73 inches (May 24) for a total of 2.33 inches. Rainfall did not affect the interpretation of the loading test impacts, as variations from the common trend of all the wells would appear at the wells being tested. The one unexplained anomaly is the fact that the fluctuations in Well 5A, although similar to the other wells, are exaggerated.

Figure 20 is a graph of the Well B water levels as testing was completed at each well's respective basin (except Basin 2, which had no B well). No observable effects of the loading were seen, as would be expected, given the fact that there was no indication of impact in the more proximal A wells.

SECTION 4 - CONCLUSIONS

4.1 Test Conclusions

Loading tests were completed for treated wastewater recharge in the Town of Barnstable at a candidate site referred to as the McManus site. The McManus site is trapezoidal in shape and encompasses approximately 11 acres. The site is wooded, undeveloped, and has rolling topography. A preliminary site investigation was conducted in 2003, indicating general suitability for wastewater recharge.

Loading tests were completed between June 6 and June 15, 2005. Testing was performed at six 10-foot basins, distributed across the site. Testing was comprised of:

1. One day of saturating the soils beneath the basins for a 24-hour period by sustaining a water level in the basins as was infiltrating out of them.

2. One day of constant head testing, during which water was fed to the basin at the same rate that water drained from the basin, as indicated by a constant water level in the basin.

3. One day of falling head testing, recording the rate at which the water level in the basins dropped. This was repeated three times.

From the constant head and falling head tests, infiltration rate in gpd/sq ft was calculated. In the constant head testing, an average infiltration rate of 106 gpd/sq ft was calculated. If Basin 4 data is rejected as not being representative of the site because of its significantly higher rate, the average infiltration rate was 90 gpd/sq ft. Applying the USEPA design factor of 10 percent to that result, an appropriate design loading rate is 9 gpd/sq ft. MADEP limits initial design loading rate to 5 gpd/sq ft until the full-scale system can be used to demonstrate higher allowable rates.

In the falling head testing, an average infiltration rate of 82 gpd/sq ft was calculated. If Basin 4 data is rejected as not being representative of the site because of its significantly higher rate, the average infiltration rate was 72 gpd/sq ft. Applying the USEPA design factor of 10 percent to that result, an appropriate design loading rate is 7 gpd/sq ft.

4.2 Estimated Site Capacity

If the data from the slowest basin from either set of testing is used as the basis for design, that average infiltration rate was 59 gpd/sq ft. Again, applying the USEPA design factor of 10 percent to that result, an appropriate design loading rate is 6 gpd/sq ft. Even applying the most conservative interpretation, the design load rate is still above and supportive of the general MADEP policy maximum of 5 gpd/sq ft.

Because a significant factor of conservation is applied to the USEPA policy of a design rate of 10 percent of the test rate, because the testing provided significant demonstration through a number of tests at a number of locations across the site, and because the MADEP guidance is extremely conservative (5 gpd/sq ft equates to 181 min/inch), Stearns & Wheler concludes that the test results demonstrate the capability of the site to receive at least 5 gpd/sq ft via open sand beds or 3 gpd/sq ft using subsurface leaching trenches.

The Town of Barnstable is considering subsurface leaching trenches as a preferred recharge technology for this site. MADEP provides guidance on the design of subsurface leaching systems. Two of the MADEP criteria that need to be considered in estimating the capacity of the site are that laterals be limited to 100 foot lengths and manifold piping be limited to 200 foot lengths. If subsurface leaching trenches are laid out in 200 foot by 100 foot fields, there is room for approximately 35 leaching fields at the site. Based on 3 gpd/sq foot and 6 square feet of infiltration area per linear foot of trench, a preliminary estimate of the capacity of the McManus site is 1.6 mgd. If 25% of the fields are set aside at any one time to allow loading to the fields to be rotated, the capacity of the site can be estimated to be 1.2 mgd.

MADEP reviewed a draft of this report and indicated that, based on the results of the testing presented, it was feasible that a greater recharge rate than 3 gpd/sq foot could be approved. Specifically, MADEP indicated that a recharge rate of 4 gpd/sq foot could be considered for the site. If the recharge rate of leaching trenches is increased from 3 gpd/sq foot to 4 gpd/sq foot the capacity of the site could increase from the 1.2 mgd cited above to 1.6 mgd.

Although the Town presently believes that subsurface leaching will be the technology employed at the site, it is still possible that rapid infiltration beds may be selected as the most appropriate alternative in the final evaluation. If rapid infiltration beds are used, the capacity of the site increases to approximately 2.1 mgd based on facility layout and the needed buffer area for this

type of technology. Whether leaching trenches or rapid infiltration beds are employed, the opportunity will exist, when full scale facilities are constructed and operational, to demonstrate additional capacity, if appropriate.

4.3 Site Availability

The Town has reviewed the suitability of using this land for effluent recharge in the context of the fact that portions of the site were acquired with Land Bank funds. The Town's legal review has concluded that the proposed use is consistent with the purposes of the land bank legislation. Correspondence related to this determination is provided as Appendix C.
