WHEREAS, the estuaries and embayments of the Popponesset Bay system have experienced greatly increased anthropogenic loads of nitrogen delivered to the water through surface and groundwater sources from the increasingly developed watershed, and that this increase in nitrogen has increased the rate of eutrophication of the waters causing adverse aesthetic, water quality and habitat impacts that result in violation of state water quality standards, all as documented in the Massachusetts Estuary Project ("MEP") report entitled, "Popponesset Bay, Total Maximum Daily Loads for Total Nitrogen (Report #96-TMDL-4, Control #217.0), MADEP, April 10, 2006."; and

WHEREAS, Mashpee, Barnstable, and Sandwich recognize that increased nitrogen loads to the embayment come from surface and groundwater sources in the watershed shared by the Parties; and

WHEREAS, the Parties believe that it is in their mutual best interests to apply jointly for a Permit for the following reasons: (1) such a Permit will provide more flexibility to achieve TMDL compliance by authorizing additional nitrogen mitigation measures beyond a traditional groundwater discharge permit issued by MassDEP; (2) a Permit will authorize opportunities for achieving compliance with the Clean Water Act through non-traditional nitrogen management approaches; and (3) the Parties will have an opportunity to share resources to achieve the mutual goal of nitrogen reduction in Popponesset Bay ("Bay"); and

WHEREAS, the Massachusetts Department of Environmental Protection (MassDEP) has developed and the USEPA has approved the Total Maximum Daily Load (TMDL) limitations for nitrogen discharges to the Bay;

WHEREAS, the Parties agree that wastewater, fertilizer, and stormwater are the prime source of controllable nitrogen causing impairment of the embayment and that, as a result, a joint effort is required to restore and protect beneficial uses and aquatic resources of the Bay and its tributaries; and

WHEREAS, each of the Parties have, to varying degrees, established or are in the process of preparing a Comprehensive Wastewater Management Plan ("CWMP") or equivalent plan, pursuant to the requirements of the MassDEP; and

WHEREAS, Attachment A to this Agreement provides the current status of the CWMP planning process for each of the Parties to this Agreement; and

WHEREAS, Mashpee, Barnstable, and Sandwich believe that it is in their mutual best interests to work cooperatively in seeking a Permit for nitrogen discharge as recommended in the 208 Plan Update, and believe that this Agreement represents the best opportunity to establish a framework of cooperation to achieve that goal.

NOW, THEREFORE, in consideration of the promises and mutual benefits to be derived by the Parties hereto, the Parties agree as follows:

1. The Parties agree that the most cost-effective means in terms of total cost, of meeting the TMDL requirements and attaining water quality and beneficial use goals may be a regional, watershed-based approach to mitigate the nitrogen at locations within the watershed where the contributing loads are the greatest and the methods useful for nitrogen reduction are the most effective.

2. Each Party will continue to develop and/or implement its own MassDEP approved CWMP or Targeted Watershed Management Plan, but shall include in their respective plan, if appropriate, any joint efforts undertaken by the Parties pursuant to this Agreement.

3. The Parties agree to jointly apply for a Permit for the Bay pursuant to the 208 Plan Update and Chapter 259 of the Acts of 2014, and any future requirements for such Permits established by MassDEP pursuant to 315 C.M.R. 5.00. If necessary and feasible, the Parties shall be joint Permittees. The joint permit application will include provisions that Mashpee will implement its plan in 5 year blocks in accordance with its approved CWMP and that Sandwich and Barnstable agree to propose a schedule that enables them to respectively complete their respective CWMP's as set forth in Attachment A, and then incorporate their planning implementation schedule in the watershed permit.

4. As the Party having the largest allocated load of nitrogen, Town of Mashpee shall serve as the fiscal agent under this Agreement and, as such, shall receive, hold, and expend any funds appropriated by the Parties for joint actions required in the implementation of this Agreement as well as any grant funds awarded to the Parties for the purpose of pursuing, securing, and implementing a Permit. Unless otherwise provided in the watershed permit or an amendment to this Agreement is made, capital projects undertaken individually by any one of the Parties pursuant to an approved CWMP or Targeted Watershed Plan shall be the sole responsibility of that Party. On December 31st and June 30th of each Fiscal Year during the term of this Agreement, Mashpee shall provide an accounting of the expenditure of funds as the fiscal agent. Any Party to this Agreement may request that Mashpee include an audit of the funds held under this Agreement as part of Mashpee's regular annual audit.

5. The Parties hereby establish a Popponesset Bay Watershed Work Group ("Work Group"), comprised of three members from each Town. The three members from each Town shall consist of the Town Manager from each Town, a member of the Town Council from Barnstable and a member of the Board of Selectmen from Mashpee and Sandwich, and a technical representative appointed by the Town Manager in each Town. Appointments shall be made in accordance with any applicable local Charter and bylaw provisions. The purposes of the Work Group will be to:

a. Administer the day-to-day joint activities of the Parties under this Agreement;

b. Coordinate with the various departments and boards of their respective towns to apply for and implement a Permit for the Bay, subject to approval by each of the Parties prior to filing;

c. Share or develop engineering and economic studies and evaluations to define means of meeting the Parties' respective nitrogen reduction targets and to develop cost-performance relationships that define most cost-effective technologies and practices for the removal of nitrogen;

d. Develop and propose for adoption amendments to this IMA, if necessary, or other forms of agreement that will define and require the action of each Party to implement agreed-upon plans to apply for and implement, a Permit;

e. The Work Group has no authority to bind one or more of the Parties. Its role shall be solely administrative in nature and to make recommendations to the Parties for actions required to implement such recommendations. The incurrence of any obligation under this Agreement by any Party shall be subject to the approval of the chief executive officer of each Party and the legislative body, if required, to implement such recommendations.

The Work Group shall be considered a public body subject to the Open Meeting Law. As the fiscal agent, Mashpee shall be responsible for posting meetings as well as preparing and distributing meeting minutes.

6. The Parties have determined that it is in their mutual best interests to establish a nitrogen allocation formula for the purpose of allocating certain costs in a fair and reasonable manner. The parties believe that the watershed permitting responsibilities should be allocated on the basis of unattenuated and attenuated nitrogen loadings. Unattenuated loads consist of the nitrogen load from the watershed contributed by septic systems, wastewater effluent, fertilizer application, storm water runoff, golf course operations, landfill activities, and natural sources. Attenuated loads are the nitrogen loadings that reach Popponesset Bay after natural attenuation in wetlands, ponds or streams, as measured at the Sentinel Testing Station. The Technical Memorandum, attached hereto as Attachment B, sets forth the technical basis agreed to by the parties for establishing the nitrogen loading allocation formulas for both unattenuated and attenuated loads as follows:

	Unattenuated	Attenuated
Barnstable	12.6%	16.0%
Mashpee	65.4%	74.5%
Sandwich	22.0%	9.5%
Total	100%	100%

The unattenuated load percentages will be used to calculate each Party's responsibility for TMDL compliance and for the tracking and accounting of implementation measures. The attenuated load percentages will be used to calculate watershed-based shared expenses including administrative costs, sentinel station monitoring costs, watershed permit application costs, watershed permit compliance costs and updates, and MEP confirmatory model runs, and such other watershed-based costs that the Parties may agree to in the future.

The allocation formula shall be reviewed every five years and will be adjusted based on any revisions to the TMDL or in accordance with a revised formula that the Towns mutually determine to be appropriate.

7. The Parties agree to adopt a fair and practical methodology for implementing the most cost-effective watershed-wide approach, in order to comply with any permits issued by MassDEP, and to share on a fair and equitable basis the capital, operating, administrative, legal, operational, and other ancillary costs associated with a regional, watershed-based wastewater and/or nutrient management system. The Towns further agree to individually fund those measures expected to achieve control of their respective share of the load identified in Paragraph 6 above unless they mutually agree to joint efforts to mitigate nitrogen.

8. The Parties agree to develop, if deemed mutually beneficial based on comparison of other wastewater management options of each Town, a fair and practical methodology for a reasonable nitrogen trading mechanism, including metrics for determining a nitrogen credit trading "currency" in terms of dollars per pound or other trading metric, as a means to implement a watershed-based plan.

9. The Parties agree to adopt, as a fair and practical methodology for monitoring the water quality of the watershed following the implementation of regional, watershed-based wastewater and/or nutrient management approaches, and the allocation of costs as agreed to in Paragraph 6 above.

10. Each Party shall cooperate with the other Parties and other entities as appropriate to identify, apply for, secure, manage and fairly allocate federal, state and other funding sources, as such may become available, to finance the planning and implementation of multi-town or regional nutrient management plans resulting from the cooperative efforts of the Parties under this Agreement.

11. Effective Date of Agreement – The effective date of this Agreement shall be the date upon which this Agreement is entered into as first written above.

12. Term of Agreement – Pursuant to G.L. c. 40, §4A, the maximum term of this Agreement shall be 25 years, recognizing, however, that any permit issued by MassDEP will likely be for a term of twenty years in 4 five year increments. Notwithstanding the foregoing, this Agreement will be reassessed at intervals of five years, or, if more stringent, in accordance with any permit renewal requirements established by the MassDEP and may be modified by mutual agreement of the Parties through an amendment of this Agreement, if necessary, to achieve permit renewal and compliance.

13. Termination – This Agreement may be terminated by any one Party upon sixty (60) days notice to the other Parties, provided, however, that any obligations created by a joint Permit issued by the MassDEP shall continue for each of the Parties unless the Permit is modified pursuant to a joint application filed by all of the Parties.

14. Dispute Resolution – In the event of a dispute arising out of or in relation to the terms of this Agreement, representatives of the Parties shall meet and endeavor to settle the dispute in an amicable manner through mutual consultation. If such persons are unable to resolve the dispute in a satisfactory manner within thirty (30) calendar days, either party may seek assistance of an independent third party, mutually-agreeable to both or all Parties.

15. Assignment - Any Party may assign to another governmental entity established for the purpose of addressing wastewater issues in the Town the responsibility in whole or in part for implementing the watershed permitting activities contemplated in the Agreement.

16. Amendment of this Agreement – This Agreement may be changed or modified through a mutually agreed upon written Amendment executed by each and all of the Parties to this Agreement. Any Amendment shall be attached to and shall become part of this Agreement.

17. Mutual Indemnification – Each party to this Agreement shall indemnify and hold harmless each and all other Parties to this Agreement, their officers, agents, consultants, employees and assigns for all liability arising out of the activities under this Agreement.

18. Subject to Appropriation – The obligations of each of the Parties shall be subject to appropriation and the availability of funds.

19. No Remuneration – Parties to this Agreement shall be solely responsible for any and all costs incurred by themselves, their agents, their employees, committee members, consultants or other persons or entities resulting from activities undertaken pursuant to this Agreement.

20. Governance – This Agreement shall be governed by, construed under and enforced in accordance with the laws of the Commonwealth of Massachusetts.

21. Severability – If any provision of this Agreement is determined to be illegal, unenforceable, or void, then all Parties shall be relieved of their obligations under that provision, provided, however, that the remainder of the Agreement shall remain in full effect.

22. Entire Agreement - This Agreement constitutes the entire agreement between the Parties.

IN WITNESS THEREOF, the Parties hereto have executed this Agreement as of the first date written above.

ATTACHMENT A

Attachment A
Town of Barnstable
CWMP Status

The Town of Barnstable has been implementing its CWMP under MEPA certificates issued on May 18, 2007, and July 20, 2012.

With the advent, in 2013, of an update of the Section 208 Water Quality Plan under the Cape Cod Commission, the Barnstable Town Council established a Water Resources Advisory Committee (WRAC) to advise the Council regarding compliance with Section 208 of the Clean Water Act relative to the Town's CWMP.

The WRAC has developed a watershed-based plan that not only addresses nutrient issues related to coastal estuaries, but the entirety of wastewater management issues throughout the Town. The Town's plan includes developing relationships with neighboring Town's with which we have shared watersheds, which include Mashpee, Sandwich, and Yarmouth.

The WRAC Plan was presented to the Town Council in July 2017.

The schedule for implementation of the plan is under advisement and discussion among Town staff and officials. Attachment A will be amended as additional information becomes available.

Memorandum

October 24, 2017

To:	Town of Mashpee, MA	Ref. No.:	11110988
From:	J. Jefferson Gregg, P.E., BCEE	Tel:	774-470-1640
cc:	File		
Subject:	**IMA – DRAFT Attachment B – Mashpee Planning Status**		

1. BACKGROUND

The Town of Mashpee, MA (Town) initiated its formal Watershed Nitrogen Management Planning (WNMP) effort in 1999 to address the Town's need for reducing nitrogen impacts to its coastal embayments and to evaluate options for restoring their water quality. At that time, the Town, through its Sewer Commission, hired GHD Inc (formerly Stearns & Wheler, LLC) to perform this planning work.

The following documents were generated as part of the planning process:

1. **Needs Assessment Report** (NAR)—issued in April 2007
2. **Technology Screening Report**—issued in November 2007
3. **Draft Alternative Scenarios Analysis and Site Evaluation Report**—issued in March 2008
4. **Two (2) Notices of Project Change**—the first issued in 2007 and the second in 2012
5. **Alternatives Screening Analysis Report** (ASAR)—issued in August 2013
6. **Draft Recommended Plan/Draft Environmental Impact Report** (DRP/DEIR)—issued in June 2014
7. **Final Recommended Plan/Final Environmental Impact Report** (FRP/FEIR)—issued May 2015

2. APPROVALS AND STATUS

Subsequent to the submittal of the above referenced documents through the Massachusetts Environmental Policy Act / Cape Cod Commission Development of Regional Impact (MEPA/DRI) review process (a joint review by State and local regulatory agencies), the following most recent approvals were received:

1. Certificate of the Secretary of Energy and Environmental Affairs on the Final Environmental Impact Report – Comprehensive Watershed Nitrogen Management Plan – EEA # 12615 – Dated July 31, 2015. This document stated that the above submitted documents: "adequately and properly complies with the Massachusetts Environmental Policy Act (MEPA) (M.G.L. c. 30, ss.61-62I) and its implementing regulations (301 CMR 11.00). No further MEPA review is required."
2. Cape Cod Commission Consistency Letter for Phase 1 of the CWNMP dated October 16, 2015. This letter states the activities proposed in Phase 1 of this document "are consistent with the 208 Plan Update and should be implemented for the benefit of the town and the region." The letter states that a formal 208 Consistency document will be forthcoming as the Cape Cod Commission (CCC) had yet

to issue formal guidance setting forth the requirements for a town to obtain 208 Plan Update consistency determination.

3. CURRENT STATUS AS OF OCTOBER 2017

The CCC has extended its DRI Public Hearing Period in anticipation of the development of a Draft Watershed Permit.

The Town of Mashpee has initiated Phase 1 of its plan as follows:

1. Initiated IMA / Watershed Permit Discussions with the neighboring communities of Barnstable and Sandwich regarding the Popponesset Bay Watershed: June 2016 to Present.
2. Initiated Feasibility Studies:
    a. Quashnet / Moonakis River Evaluation—flushing and shellfish/fin fish habitat restoration: June 2016 to Present.
    b. Mashpee Commons and Wampanoag Private WWTF evaluations: March 2016 to Present.
3. Shellfish aquaculture/propagation/restoration—Phase 1 expansion: 2016 to present.
    a. Mashpee River / Shoestring Bay—oysters.
    b. Great River / Jehu Pond / Little River / Hamblin Pond—quahogs.
    c. Department reconfiguration and expansion of personnel.
    d. Monitoring per MEP protocols with additional water quality meters deployed.

ATTACHMENT A

POPPONESSET BAY INTER-MUNICIPAL AGREEMENT
STATUS OF WASTEWATER-RELATED PLANNING FOR TOWN OF SANDWICH
25 October 2017

Sandwich has been developing its Comprehensive Water Resources Management Plan (CWRMP) since October 2012. Sandwich completed its CWRMP Needs Assessment (draft March 2012, updated draft October 2016) and its CWRMP Alternatives Analysis (draft April 2013, updated draft October 2016). Sandwich has submitted the Draft CWRMP to the Massachusetts Department of Environmental Protection for technical review and to the Cape Cod Commission for a "208 Plan Update Consistency Review". These reviews are on-going. The CWRMP will be updated to address review comments and finalized in December 2017. The CWRMP is funded by a grant received from the Commonwealth Natural Resources Damages Assessment fund and this grant expires December 31, 2017.

The Town received town meeting approval in May 2017 for an initial appropriation of $150,000 for continued planning efforts, including items such as pre-design activities, Massachusetts Environmental Policy Act (MEPA) review, Development of Regional Impact (DRI) review (if applicable). Sandwich has been, and will continue to be, involved in discussions with Joint Base Cape Cod (JBCC) and other municipal and quasi-municipal entities regarding sewer treatment capacity at the existing JBCC wastewater collection, treatment and disposal facilities.

EXHIBIT A TO INTER-MUNICIPAL AGREEMENT
TECHNICAL BASIS FOR NITROGEN LOADING ALLOCATION
Towns of Barnstable MA, Mashpee MA and Sandwich MA

Date: March 1, 2017; rev. March 14, 2017; rev. May 2, 2017
Prepared by: J. Jefferson Gregg, PE,BCEE – GHD Inc; Edward J. Leonard, PE, Wright-Pierce

BACKGROUND AND PURPOSE

Watershed nitrogen loadings to Popponesset Bay have been studied and reported on numerous times by various authors since 2000, including the studies identified below:

- MEP "Technical Report" (and associated "data disk") [Linked Watershed-Embayment Model to Determine Critical Nitrogen Loading Thresholds for Popponesset Bay, Mashpee and Barnstable, Massachusetts, Commonwealth of Massachusetts, Department of Environmental Protection, Massachusetts Estuaries Project, Final Report – September 2004]

- DEP "Revised TMDL" [Popponesset Bay Total Maximum Daily Loads for Total Nitrogen, Report #96-TMDL-4, Control #217.0, Department of Environmental Protection, December 5, 2006]

- DEP "Pilot Project Report" [Inter-Municipal Watershed Planning and TMDL Implementation to Restore Embayment Water Quality on Cape Cod, Massachusetts Department of Environmental Protection, Massachusetts Estuaries Project, Nov 2008]

- MEP "Unified Database" Memorandum [MEP Technical Memorandum, Report on Unified Database and Requested MEP Scenarios for the (a) Popponesset Bay Estuary and (b) Eastern Basins of the Waquoit Bay System, December 15, 2009]

- Mashpee "Watershed Nitrogen Management Plan (WNMP)" [Watershed Nitrogen Management Plan, Final Recommended Plan/Environmental Impact Report, GHD, May 2015]

- CCC "208 Plan Update" [208 Plan, Cape Cod Area Wide Water Quality Management Plan Update, Cape Cod Commission, June 2015]

- GHD "Allocation Memo" ["Popponesset Bay Load Allocation Approach", GHD Memorandum, May 19, 2016]

- Sandwich "CWRMP Needs Assessment" [Updated Draft Report, Wright-Pierce, October 2016]

- Sandwich "CWRMP Alternatives Analysis" [Updated Draft Report, Wright-Pierce, October 2016]

Each of these reports contributes to the body of data available for planning and implementation of watershed solutions for the Popponesset Bay system. The purpose of this memorandum is to summarize the watershed nitrogen loadings that will serve as the basis for an inter-municipal agreement (IMA) between the Towns of Barnstable, Mashpee and Sandwich.

INTRODUCTION

On June 16, 2016, representatives from the Towns of Barnstable, Mashpee and Sandwich held a kickoff meeting at the Mashpee Town Hall to discuss the development of an Inter-municipal Agreement (IMA) and the potential development of an application for a Watershed Permit as part of the effort of all three communities to address Total Nitrogen (TN) Total Maximum Daily Loads (TMDLs) for Popponesset Bay. These TMDLs were established by MassDEP and the USEPA based on the efforts of the ongoing Massachusetts Estuaries Project (MEP).

EXHIBIT A TO INTER-MUNICIPAL AGREEMENT
TECHNICAL BASIS FOR NITROGEN LOADING ALLOCATION
Towns of Barnstable MA, Mashpee MA and Sandwich MA

Date: March 1, 2017; rev. March 14, 2017; rev. May 2, 2017
Prepared by: J. Jefferson Gregg, PE,BCEE – GHD Inc; Edward J. Leonard, PE, Wright-Pierce

The key component in establishing the IMA is the agreement of each community on their share of the nitrogen load migrating to Popponesset Bay estuary through the watersheds that feed this system and include portions of each of the three communities. Following the Town of Mashpee's completion of their Comprehensive Planning efforts and the completion of the Cape Cod Commission's (CCC) recent 208 Planning efforts, GHD Inc was retained to compare three nitrogen load allocation approaches and propose an allocation that could be used in an IMA.

GHD prepared a memorandum dated May 19, 2016 entitled "Popponesset Bay Load Allocation Approach" presenting the analysis and recommendations for further discussion among the communities. This information was presented to each of the three communities and discussed during several joint meetings held on June 16, 2016, June 30, 2016, August 11, 2016 and February 15, 2017. The memorandum reviewed some previously presented allocations of nitrogen load under unattenuated and attenuated conditions and both "existing" or "baseline" conditions (considered the condition established in the MEP technical reports) and "future" conditions (build-out conditions). The Memorandum then summarized an approach of averaging such values.

During the February 15, 2017 and April 27, 2017 meetings, that included representatives of each community, the following items were agreed upon:

- CCC wMVP values would not be utilized because existing, watershed-specific information is already available (i.e., MEP original data disk and MEP "unified database").
- MEP approach (i.e., land use, water use, unattenuated loads, natural attenuation, attenuated loads and hydrodynamic assessments) is a reasonable approach.
- Allocation of responsibility would use average percent allocations based on the percent allocations established as part of the DEP Pilot Project and those established by the WNMP under the "existing" conditions. The difference between these values ranged from 0.1% to 1.0%, depending on the condition (attenuated or unattenuated) and on the community.
- Underlying data for the MEP approach will be re-evaluated in the future in the context of a watershed permit.
- Both unattenuated and attenuated loads should be presented in the IMA.
    - The purpose of presenting unattenuated loads is to provide a benchmark to allow for tracking and accounting of nitrogen reductions which result from implemented measures.
    - The purpose of presenting attenuated loads is to provide a benchmark for comparison of improvements to water quality based on implemented measures. Attenuated load is what is 'received in the estuary'.
- The allocation of responsibility for existing loads should be considered the baseline year identified in the MEP/DEP work projects (i.e., 2000/2001).
- The average values of the comparable results of the DEP Pilot Project and the Mashpee WNMP/Unified Database would be used to establish the baseline loads for the IMA.
- The parcels which have been developed or redeveloped since the baseline year represent "future conditions" in terms of TMDL compliance (i.e., there has been at least 16 years of growth since the baseline year).
- The allocation of responsibility for development or redevelopment that has occurred since the baseline year will be the responsibility of the municipality that the growth occurred in.

EXHIBIT A TO INTER-MUNICIPAL AGREEMENT
TECHNICAL BASIS FOR NITROGEN LOADING ALLOCATION
Towns of Barnstable MA, Mashpee MA and Sandwich MA

Date: March 1, 2017; rev. March 14, 2017; rev. May 2, 2017
Prepared by: J. Jefferson Gregg, PE,BCEE – GHD Inc; Edward J. Leonard, PE, Wright-Pierce

BRIEF DESCRIPTION OF NITROGEN LOADING MODELS

The tables below include the average "existing" (i.e., baseline) TN load based on the loads presented in the "rainbow"[1] spreadsheets used in the MEP analysis and those estimated based on the "unified"[2] database used in the Mashpee WNMP analysis. The primary differences in the loading estimates using the "unified" database are associated with build-out, which was the focus of the WNMP analysis in achieving TMDL compliance. However, as part of the development of the IMA, GHD was requested to generate existing loadings related to allocation estimates. In generating those numbers, two primary differences were identified in the GHD analysis when comparing to the original MEP analysis, which may have contributed to the slight increase in nitrogen load values under existing conditions:

- GHD analysis of assigning parcels to watersheds were based on the "centroid" method in GIS (where the centroid is the geometrical center of a parcel) vs. the MEP analysis where parcels were "split" and the location of septic system leaching areas relative to watershed lines were used.
- GHD used conservative average performance concentrations (for planning purposes) at the existing WWTFs in the watershed. Concentrations of either 5 mg/L or 10 mg/L TN were applied depending on the size of the facility. Estimated wastewater generation from parcels connected to each WWTF were used to estimate flows, whereas the MEP analysis used flows and concentration values for WWTFs based on "Town of Mashpee Board of Health/Planning Dept." records (per the notes provide on the "factors" worksheet in the "rainbow" spreadsheet data).

NITROGEN LOAD ALLOCATION

As part of the DEP Pilot Project, an approach was presented that if each community removed 49.2% of their share of the load, the TN TMDL could be achieved in Popponesset Bay at the sentinel station. Table 1 presents this approach, however since the Pilot Project only estimated the maximum total unattenuated load to "sustain" the threshold concentration at the sentinel station (as presented in Figure 2.15 of the Pilot Project Report), an attenuated load had to be estimated as part of this effort. This attenuated value was estimated by calculating the average attenuation by Town using the results of the analysis performed by Brian Dudley of MassDEP during the Pilot Project study. During the MassDEP effort, each Town's contribution according to the MEP dataset was divided out such that an estimated contribution by Town could be established (as that was not done as part of the original MEP efforts).

It should be noted that the Pilot Project like the WNMP and MEP technical reports all present different ways to achieve TMDL compliance by targeting different amounts of nitrogen in different subwatersheds. The Pilot Project simply attempted to streamline the process for communities using the approximately 50% reduction across the board. Therefore, it is understood that this approach may be conservative and the ultimate effectiveness of any approach will only be realized during the periodic monitoring and modeling necessary to demonstrate compliance and that will need to be defined in the Watershed Permit.

The following tables have been prepared to summarize the pertinent data from the MEP Technical Report and the DEP Pilot Project (Table 1), the WNMP/MEP Unified Database (Table 2) and the Basis for the IMA (Table 3).

Each table uses the TMDL value of 40.3 kg/day (14,710 kg/year) as the maximum attenuated load which can remain in the watershed and which would be expected to achieve the Massachusetts Water Quality Criteria, based on Table 2-5 of the TMDL Report dated December 10, 2006.

Feasibility Analysis of Shared Wastewater Treatment and Effluent Recharge between Barnstable, MA and Yarmouth, MA

Memorandum

To: *Town of Yarmouth*

From: *Kara M. Johnston, P.E.*
Hannah C. Sullivan
David F. Young, P.E.

Date: *July 2, 2019 (updated)*

Subject: *Feasibility Analysis of Shared Wastewater Treatment and Effluent Recharge between Barnstable, MA and Yarmouth, MA*

Funded by the Massachusetts Efficiency and Regionalization Grant Program and the Massachusetts Best Practices Grant Program

The Town of Yarmouth was awarded in 2018 an Efficiency and Regionalization Grant from the State's Community Compact Program. A portion of this grant was used to analyze the feasibility of shared wastewater treatment and effluent recharge between the Towns of Barnstable and Yarmouth. The Town of Harwich was awarded a Best Practices Grant in 2019 on behalf of the towns of Dennis, Harwich, Yarmouth, and Barnstable. A portion of this grant was allocated for continued analysis of wastewater treatment and effluent recharge between Barnstable and Yarmouth. The two towns share the Lewis Bay watershed and have taken the initiative to assess reducing nitrogen loading to embayments through shared commitment.

Both towns are at different phases in their Comprehensive Wastewater Management Plans. The Town of Barnstable has an existing Water Pollution Control Program which manages a collection, treatment, and recharge system, including the operation and maintenance of a secondary Water Pollution Control Facility (WPCF), 30 sewage pumping stations, and 55 miles of sewer lines. The Town is currently planning their next phases of their wastewater management plan to meet Total Maximum Daily Loads (TMDLs) for nitrogen throughout watersheds in Barnstable.

The Town of Yarmouth has been working to update their Comprehensive Wastewater Management Plan (CWMP). In 2011, the Town received state approval of their CWMP. The Town is now incorporating the Bass River Watershed into the plan and is evaluating partnership options with neighboring communities. The Town's goal is to identify a recommended program that meets the unique wastewater management challenges and economic growth goals of Yarmouth. The Town's Water Resources Advisory Committee (WRAC) is updating the CWMP and the Town plans to file a Notice of Project Change (NPC) with the Massachusetts Environmental Policy Act (MEPA) Office and the Cape Cod Commission (CCC) for regulatory review in 2019.

The purpose of this memorandum is to present the various alternatives that have been developed for the towns to coordinate shared wastewater treatment and effluent recharge. There are numerous potential routes to convey Yarmouth's wastewater from the Lewis Bay Watershed to Barnstable's Water Pollution Control Facility. Upon treatment at the existing WPCF, the effluent could be conveyed to a town-owned site on Buck Island Road in Yarmouth where it would be recharged into the ground. Two potential routes were evaluated from the WPCF to the Buck Island Road Recharge Site. The towns developed 8 alternatives with varying factors that include:

- The locations where redundant force mains could be installed;
- The wastewater conveyance routes from the Lewis Bay Watershed in Yarmouth to the WPCF in Barnstable; and
- The treated effluent conveyance routes from the Barnstable WPCF to the Buck Island Road Recharge Site in Yarmouth.

The majority of these alternatives account for 365,000 gpd of flow from the Lewis Bay Watershed in West Yarmouth and 100,000 gpd of flow from a potential new sewer area in Barnstable off of Yarmouth Road.

The Barnstable WPCF has a current treatment capacity of 4.2 million gallons per day (MGD) maximum day and effluent discharge capacity of 2.7 MGD maximum day. It is estimated based on transient groundwater modeling that the Buck Island Road Recharge Site has a capacity of 870,000 gpd to 1.2 MGD, depending on the concentration of total nitrogen (TN) in the effluent to be discharged. It is assumed in the alternatives below that Barnstable could purchase the remaining capacity not used by Yarmouth at the Buck Island Road Recharge Site.

1.0 Pipe Conveyance Redundancy Scenarios

When evaluating pipe conveyance routes between the communities, the towns discussed the need for force main redundancy for both the wastewater force main and the effluent force main. The Town of Barnstable prefers that a redundant pipe be installed alongside all force mains within the town. Barnstable has expressed concern that the Town would not be able to recharge the Barnstable/Yarmouth effluent in town in the event of an effluent pipe force main break on its way to the Yarmouth Buck Island Road Recharge Site. An effluent force main repair carrying treated effluent would be similar to a water main repair and CDM Smith anticipates that the line could be fixed fairly quickly. In accordance with this discussion between the communities, two redundancy scenarios have been analyzed for each route option that is discussed in Sections 2 and 3. The communities would need to discuss the redundancy impacts on costs and future operations.

Redundancy Scenario 1: All force mains installed in both Barnstable and Yarmouth include a redundant pipe installed in the same trench. This includes both the force main conveying wastewater to the Barnstable WPCF, as well as the force main conveying treated effluent to the Buck Island Road Recharge Site.

Redundancy Scenario 2: Only the force main that conveys wastewater to the Barnstable WPCF in Barnstable and Yarmouth includes a redundant pipe installed in the same trench. Force main conveying treated effluent to the Buck Island Road Recharge Site include a single pipe in both towns.

2.0 Wastewater Conveyance Routes from Yarmouth to Barnstable

In order to convey a portion of Yarmouth's wastewater from the Lewis Bay watershed to the Barnstable WPCF for treatment, various potential routes have been analyzed for cost and efficiency. Routes were developed in discussions between Barnstable and Yarmouth representatives. All four of the routes begin by collecting 365,000 from the Yarmouth Pumping Station on Route 28 in the Lewis Bay Watershed and end at the Barnstable WPCF on Bearses Way in Barnstable. Options 2A and 3 collect an additional 100,000 gpd of buildout flow from the area of Barnstable that is north of Route 28 and east of Yarmouth Road. Attachment A includes figures for the conveyance options that are described in more detail below, along with a summary figure showing all the wastewater and effluent conveyance options.

2.1 Wastewater Conveyance Option 1 - Direct Route

Conveyance Option 1 is to convey the wastewater along the most direct route within Route 28, a state-owned roadway. The wastewater would be pumped via a 6" force main from the Yarmouth Pumping Station west along Route 28 and up Bearses Way to the Barnstable WPCF for treatment. The total length of force main installed would be approximately 2.5 miles, with 2.3 miles of that on a state road. The cost to install force main along a state roadway is significantly higher than on a local road due to the necessity of additional police detail, state backfill and paving requirements, permitting, and potential required nightwork. The potential flow proportion between Barnstable and Yarmouth was developed based on the percentage of flow that each town would contribute to each pipe segment. Figure 1 in Attachment A shows this wastewater conveyance route.

2.2 Wastewater Conveyance Option 2A – via Existing Gravity Sewer System and Old Colony Pumping Station with Barnstable Flow

The second option for conveying wastewater to the Barnstable WPCF makes use of Barnstable's existing gravity sewer system. The wastewater would be pumped from the Yarmouth Pumping Station, west along Route 28, up Camp Street, and down Mill Pond Village to the shared B/Y Pumping Station facility via a 6" force main. From there, the wastewater would be pumped down Yarmouth Road via a 6" force main where it would then tie into Barnstable's existing 8" gravity sewer at the intersection of Yarmouth Road and Camp Street. The wastewater would then flow by gravity through the existing collection system to Barnstable's Old Colony Pumping Station at the corner of South Street and Old Colony Road. From there, the wastewater would be pumped through a new 10" force main down South Street, up High School Road, and up Bearses Way to the WPCF for treatment. The additional flow from the two towns of approximately 465,000 gpd into Barnstable's existing collection and conveyance system would likely require some necessary pipe size upgrades. Figure 2 in Attachment A shows this wastewater conveyance route.

2.3 Wastewater Conveyance Option 2B – via Existing Gravity Sewer System and Old Colony Pumping Station without Barnstable Flow

Similar to Conveyance Option 2A, this alternative incorporates Barnstable's existing gravity sewer system into the shared wastewater conveyance plan. However, instead of installing a force main up to Ferndoc Street to the proposed shared pumping station, a force main would be installed from the Yarmouth Pumping Station, west along Route 28 to Main Street in Barnstable where it would tie into Barnstable's existing 8" gravity sewer. In this Option 2B, the shared pumping station on Ferndoc Street would not be installed and the new collection system in the area of Barnstable north of Route 28 and east of Yarmouth Road would be conveyed separately through Barnstable's sewer system. Therefore, the only additional wastewater conveyed to the Barnstable WPCF would be the 365,000 gpd of buildout flow from Yarmouth.

Once tying into the existing collection system, the wastewater would flow by gravity to the Old Colony Pumping Station where it would then be pumped through the existing 10" force main down South Street, up High School Road, and up Bearses Way to the WPCF. To accommodate the additional 365,000 gpd of buildout flow in the collection and conveyance system, some upgrades to the gravity sewers and force main would likely be necessary. Figure 3 in Attachment A shows this wastewater conveyance route.

2.4 Wastewater Conveyance Option 3 – via Municipally Owned Roads (through Airport and Shopping Center)

Option 3 was developed with the intent of avoiding the additional permitting and costs associated with installing new pipe on the state-owned Route 28. The Town of Barnstable owns the Hyannis Airport property and the adjacent shopping center. The Town of Barnstable proposed that the airport access road and adjacent shopping center parking lot be used in place of Route 28 between Yarmouth Road and Airport Road. In this case, wastewater would be pumped from the Yarmouth Pumping Station, west along Route 28, up Camp Street and down Mill Pond Village to the proposed shared B/Y Pumping Station on Ferndoc Street. The wastewater would flow down Yarmouth Road for a short distance until turning west at 326 Yarmouth Road and continue along a cross country route through the municipally owned airport land to the airport service road. It would then follow the service road until reaching Barnstable Road which connects the airport to the municipal owned shopping plaza parking lot. Upon crossing through the parking lot, the force main would turn down Airport Road to Route 132 where it would then follow the state road for approximately a tenth of a mile. Next, it would turn down Independence Drive to Enterprise Road until reaching Bearses Way where the Barnstable WPCF is located. Although this route is approximately 1.3 miles longer than the direct route, there would be no work on Route 28 in Barnstable. Figure 4 in Attachment A shows this wastewater conveyance route.

2.5 Wastewater Conveyance Route Options Summary

All conveyance route options were analyzed under both redundancy scenarios. However, since both scenarios require redundant wastewater force main, the total wastewater conveyance cost remains the same under both scenarios for each of the route options discussed in this section. A cost estimate for each of the four wastewater conveyance route options has been developed and is

presented in Table 1. All costs are projected to Year 2022 with an estimated Engineering News Record (ENR) Construction Cost Index of 12,400. The ENR Index is an industry standard index for tracking costs over time. Force main cost estimates include temporary trench width paving followed by mill and overlay, costs for jack and boring beneath railroad crossing where applicable, and consider additional costs for work on a state road where applicable. The potential flow proportion split between Barnstable and Yarmouth was developed based on the percentage of flow that each town would contribute to each pipe segment. Flow proportions are just one potential cost sharing method for discussion; other potential methods would be further discussed and negotiated between the communities.

Table 1 - Wastewater Conveyance Options Opinion of Probable Cost (For Redundancy Scenarios 1 and 2)

	Total Cost[1]	Potential Flow Proportions		Potential Flow Proportion Percentages for Shared Infrastructure	
		Barnstable	Yarmouth	Barnstable	Yarmouth
OPTION 1 - DIRECT ROUTE VIA ROUTE 28	$7.87 Million	0 gpd	365,000 gpd	0%	100%
OPTION 2A – VIA OLD COLONY PUMPING STATION W/ BARNSTABLE FLOW	$14.44 Million	100,000 gpd	365,000 gpd	22%	78%
OPTION 2B – VIA OLD COLONY PUMPING STATION W/O BARNSTABLE FLOW	$10.26 Million	0 gpd	365,000 gpd	0%	100%
OPTION 3 – VIA MUNICIPALLY OWNED ROADS THROUGH AIRPORT AND SHOPPING CENTER	$11.50 Million	100,000 gpd	365,000 gpd	22%	78%

[1]The cost of the Yarmouth Mill Creek Pumping Station and associated force main is included in the total costs in Table 1, but is not assumed to be shared infrastructure with Barnstable.

3.0 Treated Effluent Conveyance Routes from Barnstable to Yarmouth

Similar to wastewater conveyance, there are multiple potential routes for the treated effluent conveyance from the Barnstable WPCF to the Buck Island Road Recharge Site in Yarmouth. The figures in Attachment A depict the two routes developed for the conveyance of the treated effluent. Both of these effluent conveyance options were analyzed under each of the redundancy scenarios. Scenario 1 includes effluent force main redundancy whereas Scenario 2 includes a single effluent force main. As discussed in Section 1, the communities will need to discuss the redundancy impacts on costs and future operations.

3.1 Effluent Conveyance Option 1 - Direct Route

Effluent Conveyance Option 1 is to convey the effluent along the most direct route. This is essentially the reverse of the wastewater conveyance Option 1 route; however, the force main continues to the Buck Island Road Recharge Site. The effluent force main would travel from the Barnstable WPCF, east on Route 28. From there, the effluent force main would turn up Town Brook Road and follow Buck Island Road to the Buck Island Road Recharge Site. The total cost and the

potential flow proportion percentages between the two towns for sending the effluent to the Buck Island Road Recharge Site is shown in Table 2.

Table 2 - Treated Effluent Conveyance Option 1 (Direct Route via Route 28) Opinion of Probable Cost

	Total Cost	Potential Flow Proportions[1]		Potential Flow Proportion Percentages	
		Barnstable	Yarmouth	Barnstable	Yarmouth
Redundancy Scenario 1 *(Redundant sewer and effluent force main in Barnstable and Yarmouth)*	$12.87 Million	835,000 gpd	365,000 gpd	70%	30%
Redundancy Scenario 2 *(Redundant sewer force main in Barnstable and Yarmouth only)*	$6.77 Million	835,000 gpd	365,000 gpd	70%	30%

[1]Effluent Conveyance Option assumes nitrogen upgrade to Barnstable WPCF to TN discharge of 3 mg/L.

If either wastewater conveyance Option 2A or 2B is selected in conjunction with effluent conveyance Option 1, then an additional cost would be included for pipe jacking at the railroad crossing.

3.2 Effluent Conveyance Option 2- via Municipally Owned Roads (through Airport and Shopping Center)

Similar to wastewater conveyance Option 3, this route was developed to avoid work on state owned Route 28 by way of the municipally owned airport service road and shopping plaza parking lot. The route is the reverse of the wastewater Option 3 route until reaching Camp Street where it would then follow Buck Island Road to the Buck Island Road Recharge Site. Table 3 shows the total cost under each redundancy scenario for this effluent conveyance route option as well as the potential flow proportion percentages based on the amount of additional flow in each pipe segment.

Table 3 - Treated Effluent Conveyance Option 2 (via Municipally Owned Roads) Opinion of Probable Cost

	Total Cost	Potential Flow Proportions[1]		Potential Flow Proportion Percentages	
		Barnstable	Yarmouth	Barnstable	Yarmouth
Redundancy Scenario 1 *(Redundant sewer and effluent force main in Barnstable and Yarmouth)*	$14.77 Million	835,000 gpd	365,000 gpd	70%	30%
Redundancy Scenario 2 *(Redundant sewer force main in Barnstable and Yarmouth only)*	$7.78 Million	835,000 gpd	365,000 gpd	70%	30%

[1]Effluent Conveyance Option assumes nitrogen upgrade to Barnstable WPCF to TN discharge of 3 mg/L.

4.0 Barnstable Water Pollution Control Facility (WPCF)

The Barnstable WPCF has a current average daily flow of 1.57 million gallons per day (MGD). The Town has hired a consultant to create a BioWin model of the plant to evaluate its treatment capacities and is awaiting the results of the study. The current estimates are that the town has about 1.0-2.0 MGD of treatment capacity available, and about 1.0 MGD of disposal capacity available, some of which is currently allocated for future sewer phases in Barnstable. Additionally, Barnstable is currently evaluating its pumping stations throughout town to estimate the capacity, condition, and needs assessment for each station.

The Town of Barnstable has plans for future phases to meet their nitrogen TMDL goals. It is not anticipated that the wastewater flow from Yarmouth would significantly impact future Barnstable flows at the WPCF. The Town of Barnstable's permitted flow from their November 5, 2018 issued discharge permit is 2.7 MGD, with the an associated mass loading limit based on an annual average of 6 mg/L Total Nitrogen. The maximum daily limit of Total Nitrogen permitted is 10 mg/L.

Because of the studies underway, the costs for upgrades at the Barnstable WPCF are unknown at this time and are not included in the cost estimates in this memorandum. The need for pumps and wet well storage to pump effluent to the Buck Island Road Recharge Site are also unknown at this time and are not included in the cost estimates in this memorandum.

5.0 Buck Island Road Recharge Site in Yarmouth

Once the wastewater has been treated and conveyed to the Buck Island Road Recharge Site, the highly treated effluent would be recharged into the ground via infiltration basins. The Buck Island Road Site was selected as a potential recharge site for a variety of reasons:

- Site is outside of any Zone II areas, meaning the aquifer at this site does not contribute to a drinking water well;
- Site is owned by the Town of Yarmouth;
- Subsurface soil characteristics are desirable for infiltration of the recharge into the groundwater as prior investigations have shown the subsurface is predominately sandy soil and not dense clay.

The Town of Yarmouth has assessed the nitrogen balance of the Parkers River watershed in their sewer plan, including the widening of the Parkers River Bridge on Route 28 which will provide increased flushing. Under the Town's current plan, the Upper Parkers River subwatershed where the Buck Island Road Effluent Recharge Site is located is planned to be fully sewered to meet the watershed's TMDL. If Barnstable and Yarmouth recharge effluent at the Buck Island Road Recharge Site, additional nitrogen from the effluent will enter the groundwater in the Parkers River Watershed and will need to be removed to meet the watershed's TMDL.

The Buck Island Road Recharge Site was previously analyzed to quantify the recharge capacity of the site. The 10-acre site is estimated to be able to hydraulically recharge a total of 1.2 MGD of

effluent at a WPCF nitrogen discharge of 3 mg/L. A permeable reactive barrier (PRB) has been proposed to achieve additional nitrogen removal surrounding the Buck Island Road Recharge Site after treatment, reducing the nitrogen discharge of 3 mg/L to 1 mg/L. The Cape Cod Commission's Section 208 Plan provides an estimate nitrogen removal for PRBs at 75-90% removal. CDM Smith performed a PRB analysis in Falmouth, MA where an 80% nitrogen removal rate was found to be anticipate through a PRB based on literature citations. For the Buck Island Road Recharge Site, an 80% nitrogen removal rate is expected to be achieved through a PRB, meaning a WPCF TN discharge of 3 mg/L would be lowered to approximately 1 mg/L. Based off the site capacity of 1.2 MGD, the barrier would stretch approximately 2,600 linear feet.

Per the Individual Groundwater Discharge Permit issued to the Barnstable WPCF on November 5, 2018, the treatment facility has a current nitrogen maximum daily effluent discharge limit of 10 mg/l and is not to exceed 49,315 pounds per calendar year based on a maximum daily flow of 2.7 MGD and an annual average Total Nitrogen concentration of 6 mg/l. It is assumed that a PRB could remove 80% of additional nitrogen from the effluent discharge. If there were no nitrogen upgrades at the Barnstable WPCF and the effluent is treated to the annual average TN concentration of 6 mg/l, the 10-acre Buck Island Site has a recharge capacity of approximately 870,000 gpd. Approximately 365,000 gpd of the flow under this option with a TN discharge of 6 mg/L would be contributed from the Town of Yarmouth, and the remaining 505,000 gpd of the flow could be contributed from the Town of Barnstable.

The Barnstable WPCF would need to be upgraded to meet an effluent limit of 3 mg/L Total Nitrogen in order to discharge 1.2 MGD of effluent in the Upper Parkers River subwatershed. Because the costs to upgrade the Barnstable WPCF are unknown at this time, the costs associated with meeting an effluent limit of 3 mg/L TN are also unknown and are not included in the cost estimates in this memorandum.

All alternatives have been analyzed with 365,000 gpd of flow from Yarmouth being sent to the WPCF and ultimately to the Buck Island Road Recharge Site for recharge. Under the current WPCF's average TN discharge of 6 mg/L, Barnstable could contribute 505,000 gpd of effluent recharge at the Buck Island Road Recharge Site. If the WPCF is upgraded to a TN discharge of 3 mg/L the Town of Barnstable could contribute up to 875,000 gpd.

The costs for the lease of the Yarmouth Buck Island Road Recharge Site are unknown at this time and are not included in the estimates below or in this memorandum. Table 4 shows the total cost and the potential flow proportion percentages for the effluent recharge site based on the 1.2 MGD site capacity if the Barnstable WPCF upgraded to treat to 3 mg/L TN.

Table 4 - Effluent Recharge Site Opinion of Probable Cost

Item	Total Cost	Potential Flow Proportions		Potential Flow Proportion Percentages	
		Barnstable	Yarmouth	Barnstable	Yarmouth
Buck Island Road Recharge Site	$6.05 Million	835,000 gpd	365,000 gpd	70%	30%
PRB	$8.10 Million	835,000 gpd	365,000 gpd	70%	30%

6.0 Operation and Maintenance Costs

In addition to the capital cost, the operations and maintenance costs have been estimated for all the alternatives. The unit costs to operate and maintain each component of the wastewater management plan are shown in Table 5.

Table 5 - Unit O&M Costs

Item	Unit	Unit Cost
Gravity Main	linear foot	$2.00
Sewer Force Main	linear foot	$1.00
Effluent Force Main	linear foot	$1.00
Pumping Station	each	$62,500.00
Effluent Recharge O&M	square foot	$0.17
PRB O&M	each	$55,000.00

Because the costs to upgrade the Barnstable WPCF are unknown at this time, the O&M costs associated with these upgrades are also unknown and are not included in the cost estimates in this memorandum.

7.0 Summary & Recommendation

The various alternatives for treatment and recharge of Barnstable and Yarmouth flow each provide various advantages and disadvantages. A summary table of the total cost and potential flow proportion percentages for both Barnstable and Yarmouth in each scenario and conveyance option is shown in Table 6.

Table 6 - Overall Cost Summary Table

		Scenario 1 - Redundant Sewer Force Main and Effluent Force Main	Scenario 2 - Redundant Sewer Force Main
OPTION 1 - DIRECT ROUTE VIA ROUTE 28	Capital Cost	$34.9 Mil	$28.8 Mil
	O & M Cost	$297,550	$270,750
	Barnstable Wastewater Flow Proportion	0%	0%
	Yarmouth Wastewater Flow Proportion	100%	100%
OPTION 2A - VIA EXISTING GRAVITY SEWER SYSTEM, W/ BARNSTABLE FLOW	Capital Cost	$41.6 Mil	$35.5 Mil
	O & M Cost	$411,100	$332,200
	Barnstable Wastewater Flow Proportion	22%	22%
	Yarmouth Wastewater Flow Proportion	78%	78%
OPTION 2B - VIA EXISTING GRAVITY SEWER SYSTEM NO BARNSTABLE FLOW	Capital Cost	$37.4 Mil	$31.4 Mil
	O & M Cost	$334,800	$310,800
	Barnstable Wastewater Flow Proportion	0%	0%
	Yarmouth Wastewater Flow Proportion	100%	100%
OPTION 3 - VIA MUNICIPALLY OWNED ROADS THROUGH AIRPORT AND SHOPPING CENTER	Capital Cost	$40.4 Mil	$33.4 Mil
	O & M Cost	$350,850	$322,550
	Barnstable Wastewater Flow Proportion	78%	78%
	Yarmouth Wastewater Flow Proportion	22%	22%

After further evaluation of the current flows at the Old Colony Pumping Station, the Town of Barnstable's preference is to not convey additional flow to the Old Colony Pumping Station. Therefore, the wastewater conveyance options 2A and 2B are not recommended at this time.

Conveyance and Effluent Recharge Option 1 provides the most direct and cost-effective route, but includes work on Route 28 in both communities. Conveyance Option 3 (with Effluent Recharge Conveyance Option 2) takes advantage of Barnstable-owned property to avoid work on Route 28, but is more costly due to the longer pipe distance, and the inclusion of a shared Barnstable/Yarmouth pumping station to accommodate an additional 100,000 gpd of wastewater flow from the Town of Barnstable.

If Barnstable and Yarmouth choose to move forward with a partnership, community leaders will need to discuss the implications of both of these options. Considerations will need to review:

- Capital costs;
- Operations;
- Force main redundancy;
- Impacts to state/town roads;

- Impacts to the Barnstable WPCF;
- Nitrogen impacts in the Parker's River Watershed.

An intermunicipal agreement (IMA) could be considered to formalize the partnership. The costs associated with nitrogen upgrades at the WPCF, costs for the effluent pumping station at the WPCF and for utilizing the Buck Island Road recharge site would all need to be further discussed.

As part of this grant, a series of meetings were held between Barnstable and Yarmouth to discuss the alternatives described above. Minutes from these meetings are included in Attachment B.

Barnstable - Yarmouth Wastewater Meeting Minutes

Date: 05/31/2018
Time: 2:00 PM
Location: Barnstable DPW
Attendees: Griffin Beaudoin, Andy Boule, Elizabeth Jenkins, Amanda Ruggerio, Dan Santos, Rob Stein (Barnstable)

Rich Bienvenue, Jeff Colby, Kelly Grant, Karl von Hone (Yarmouth)

Kara Johnston, Dave Young (CDM Smith)

1. Grant Overview: Barnstable – Yarmouth Subtasks ($50,000)
2. Wastewater Discussions
    a. Barnstable - Current WWTP and Effluent Recharge Capacity
        i. Current and future flows
        ii. Collection system/pump station capacity for potential Yarmouth tie-in location: embarking on a comprehensive evaluation of pump stations. The will be kicked off next month and the final evaluation report will be issued in the Spring of 2019.
        iii. Flows that would trigger a treatment plant expansion + associated costs of component expansions/upgrades. Barnstable hired a consultant to create a BioWin model of the plant to estimate its treatment capacities. This model is expected to be completed in October 2018. Additionally, Barnstable is working with DEP on a new Permit for the facility which may have bearing on the issue.
    b. Yarmouth – Buck Island Road Effluent Recharge Capacity
    c. Barnstable – Current and Future Flows
    d. West Yarmouth – Anticipated Buildout Flows

MEETING MINUTES

Barnstable – Yarmouth Wastewater

Date: July 16, 2018
Time: 1:30 PM
Location: Town of Barnstable Department of Public Works

Attendees: Griffin Beaudoin, Andy Boule– Town of Barnstable

Jeff Colby – Town of Yarmouth

Kara M. Johnston, David F. Young – CDM Smith

Meeting Summary:

- Buck Island Road Effluent Recharge Site Capacity: 1.2 – 2.0 MGD (Additional testing will be required to reach higher range)
- Hospital ties into Old Colony Pumping Station. Barnstable currently evaluating the station's upgrades needs.
- Mill Pond Affordable Housing in Yarmouth owned by a private developer. Potential to discuss easement on this site with owner for a shared pumping station. Developer wants to add more units.
- Potential Routes between Yarmouth and Barnstable (for wastewater treatment and effluent recharge):
  - Option 1: Route 28 (straight shot)
  - Option 2: Tying into existing collection system and Old Colony Pumping Station (collection system and pumping station would both require upgrades)
  - Option 3: Through Airport and Kmart Plaza (town owned), Route 132, Enterprise Road
- Barnstable to review force main redundancy policy
- Barnstable to review town policy for access at airport for O&M
- CDM Smith to confirm flows from Yarmouth / Lewis Bay area
- Barnstable WWTP:
  - 2 MGD current
  - 2.7 MGD with all of Phase 1
  - Nitrogen: 6-10 ppm
  - Aeration train upgrade may be needed with additional flow from Yarmouth
  - Upgrading solids handling in approximately 5 years. Yarmouth evaluating anaerobic digester at septage facility.
- Triangle Sewer Area – approx. 0.3 MGD at full buildout
- Buck Island – may need a reserve capacity for Yarmouth septage plant + Yarmouth Flow from Yarmouth to Barnstable + Remaining portion of site capacity would be available for Barnstable

- Need to check nitrogen balance if additional sewering would be required in Parkers River for effluent recharge added at Buck Island

Assigned To	Action Item
CDM Smith	Send PDF of Ongoing/Future MassDOT Projects
Barnstable	Send PDF of Barnstable System Map - "Figure 5-2"
Barnstable	Review Town Policy for force main/redundancy
Barnstable	Review Town Policy for airport access/future O&M – any restrictions?
Barnstable	Confirm flow from "triangle sewer area" (current and buildout)
Barnstable	Provide Old Colony Pumping Station capacity information and pipe sizes for collection system requiring upgrades between Yarmouth and WWTP through Old Colony Pumping Station

MEETING MINUTES

Barnstable – Yarmouth Wastewater

Date: November 2, 2018
Location: CDM Smith – Yarmouth Office

Attendees: Jeff Colby – Town of Yarmouth

Kara M. Johnston, David F. Young – CDM Smith

Meeting Summary:

- Review of Scenarios and Options for Barnstable/Yarmouth Wastewater:
  - Option 1 – Direct via Route 28
  - Option 2 – Via Old Colony PS
  - Option 3 – Via Airport Road
  - Scenario 1 – Redundant Sewer Force Main and Effluent Force Main in Barnstable and Yarmouth
  - Scenario 2 – Redundant Sewer Force Main in Barnstable and Yarmouth
  - Scenario 3 – Redundant Sewer Force Main in Barnstable Only

- Timing of Barnstable triangle sewer area?
- P.S. on Route 28 in Barnstable? East Main Street?
- Discussion of sleeves under railroad line
- Schedule meeting with Barnstable to review scenarios and options

MEETING MINUTES

Barnstable – Yarmouth Wastewater

Date: November 8, 2018
Location: Town of Barnstable Department of Public Works

Attendees: Griffin Beaudoin, Andy Boule– Town of Barnstable

Jeff Colby – Town of Yarmouth

Kara M. Johnston, David F. Young – CDM Smith

Meeting Summary:

- Review of Scenarios and Options
  - Option 1 – Direct via Route 28
  - Option 2 – Via Old Colony PS
  - Option 3 – Via Airport Road
  - Scenario 1 – Redundant Sewer Force Main and Effluent Force Main in Barnstable and Yarmouth
  - Scenario 2 – Redundant Sewer Force Main in Barnstable and Yarmouth
  - Scenario 3 – Redundant Sewer Force Main in Barnstable Only

- Discussion of new "Option 2B" where Yarmouth would tie into Barnstable sewer system off of Main Street

Assigned To	Action Item
CDM Smith	Add "Option 2B"

MEETING MINUTES

Barnstable – Yarmouth Wastewater

Date: June 21, 2019

Location: Town of Barnstable Department of Public Works

Attendees: Griffin Beaudoin, Andy Boule, Rob Steen– Town of Barnstable
Jeff Colby – Town of Yarmouth
Kara Johnston, David Young – CDM Smith

Meeting Summary:

- Discussion of comments from Town of Barnstable:
  - Remove potential cost allocations from tables– to be discussed by community leaders at a later date.
  - Effluent pipe redundancy is important for Barnstable since effluent that would be sent to Yarmouth could not be recharged at other sites in Barnstable in the event of a force main break. However, CDM Smith suggested that like a water main repair effluent force main could be fixed fairly quickly.
  - The draft memo will be updated to reflect these comments, and others discussed during 6/21/2019 meeting.
- Grant Update:
  - The Efficiency and Regionalization Grant previously obtained by the Town of Yarmouth has been closed out. A draft of the Barnstable-Yarmouth Memo was sent to the agency, but memo is still a working document and has not been finalized.
  - The Town of Harwich obtained an additional grant on behalf of the four towns through the MA Best Practices Grant Program. $40,000 for DHY and $10,000 for Barnstable-Yarmouth.
- Review of Route Options:
  - Option 1: Revised "direct route" along Route 28.
  - Option 2A: Old Colony Pumping Station is no longer a preferred route for Barnstable. CDM Smith will add language in memo to further explain. High flows to the station currently, and potential for future hospital expansion.
  - Option 2B: Old Colony Pumping Station is no longer a preferred route for Barnstable. CDM Smith will add language in memo to further explain. High flows to the station currently, and potential for future hospital expansion.
  - Option 3: Revise to avoid Route 28 altogether. Griffin will send preferred route to Airport Road (received 6-26-19).
- Cost Allocation Discussion:
  - Remove reference to cost allocation between communities in the tables. Change to percentage flow proportions instead.
  - Future cost allocations would be discussed and negotiated at a later date.

- Redundancy Scenarios Discussion:
  - Scenario 1 includes full redundancy of sewer and effluent force mains.
  - Scenario 2 includes redundancy of sewer force mains, and not of effluent force main.
  - Scenario 3 will be removed from the memo (effluent force main redundant in Barnstable, and not in Yarmouth).
  - Additional language will be added to memo to describe Barnstable's preference for redundancy of effluent force main. In the event of a force main break, Barnstable expressed concern they would not be able to recharge the Barnstable/Yarmouth effluent in town. However, CDM Smith suggested that like a water main repair effluent force main could be fixed fairly quickly.
- Discussion of recharge at the Buck Island Road Recharge Site and nitrogen loading in the Parkers River Watershed:
  - At Total Nitrogen level of 3 mg/l WPCF discharge, the Buck Island Road Recharge Site can accept 1.2 MGD.
  - The potential capacity at the Buck Island Road Recharge Site at 6 mg/l of Total Nitrogen at WPCF discharge was further evaluated by CDM Smith after the meeting on 06/21/2019. With the assumption of additional nitrogen removal by a permeable reactive barrier (PRB), the Buck Island Road Recharge capacity at 6mg/l Total Nitrogen is estimated to be 870,000 gpd. Revisions will be made to the memo to reflect the assumptions associated with this calculation. The recharge at 3mg/l Total Nitrogen is 1.2 mgd.
  - CDM Smith will revise memo to discuss Barnstable's current max day permit level of 10 mg/l Total Nitrogenas.
  - Barnstable has discussed denitrification filters at the WPCF, but is still evaluating.
- Review of Griffin's comment email from 5/29/2019:
  - *Barnstable Question 1:* "As noted, WPCF cannot currently treat to 3 mg/L. The average daily TN from WPCF is 6 mg/L. At 6 mg/L, what is the disposal capacity of the Buck Island disposal site?"
  - *Response 1:* A paragraph has been added to Section 5 of the Memo to discuss this in more detail. Further edits will be made in the memo to discuss the potential capacity at the Buck Island Road Recharge Site with additional nitrogen removal from a PRB.
  - *Barnstable Question 2:* "Cost allocation assumptions should be removed. Total project costs should be presented. Cost allocation is an item that would be negotiated at a later date."
  - *Response 2:* Cost allocations will be removed from the memo. A percent of "flow proportion" will be shown in its place.
  - *Barnstable Question 3:* "The Route 28 scenario ("straight shot") discussed at the 7/16/18 meeting is not reflected as a wastewater conveyance scenario. This scenario should be included in the analysis."
  - *Response 3:* Route Option 1 has been revised to include this scenario.
  - *Barnstable Question 4:* "Redundancy Scenario 3: A redundant force main in one town only is an operational issue. Suggest removing this scenario and replacing with a redundancy scenario analyzing redundant effluent force mains only instead. If a single effluent force main were to be damaged, there would be no option for disposal above the permitted capacity of the WPCF beds."

- *Response 4:* Redundancy Scenario 3 will be removed from the memo. Scenario 1 includes sewer and effluent force main redundancy. As discussed at previous meetings, the costs will be shown for redundant sewer and single effluent force main. Additional language will be added to the memo to describe Barnstable's desire for redundant force main to the effluent recharge site since there is no other available recharge locations within Barnstable for that flow if the pipe couldn't be fixed quickly.
- *Barnstable Question 5:* "Is the cost of the proposed Barnstable / Yarmouth Pumping Station included in the cost estimates?"
- *Response 5:* Yes
- *Barnstable Question 6:* "Utilizing Old Colony Pump Station is not our preferred scenario at this time."
- *Response 6:* Further language has been added to the memo Summary Section 7 to describe this.
- Barnstable Question 7: "The wastewater and effluent force mains should follow the same routes under the recommended scenario."
- *Response 7:* Route Option 3 will be revised to avoid Route 28.
- *Barnstable Question 8:* "WPCF's nitrogen permit level is not 6 mg/L as suggested. The permit level is 10 mg/L. The nitrogen mass load is based upon an average of 6 mg/L at 2.7 MGD."
- *Response 8:* Language revised to match Barnstable's permit. 10 mg/L max day permit level for Total Nitrogen to be added to the memo as well.
- *Barnstable Question 9:* Recommend modifying the Potential Routes figure as it is difficult to follow.
- *Response 9:* Separate figures created for each route option.

▪ CDM Smith will revise memo and send to the group for further comments.

Assigned To	Action Item
CDM Smith	Remove reference to potential cost allocations and show flow proportions as percentages
Griffin Beaudoin	Send preferred route through Airport Road
CDM Smith	Revise Route Option 3 with revised Airport Road access (text and figures)
CDM Smith	Remove Redundancy Scenario 3
CDM Smith	Add "10 mg/l max day Total Nitrogen Permit Level" to memo
CDM Smith	Add language on Old Colony Pumping Station as no longer being a feasible route
CDM Smith	Revise memo and send to group for further comments
CDM Smith	Send 6/21/2019 meeting minutes to the group for comment

1 EXECUTIVE SUMMARY

1.1 BACKGROUND

Joint Base Cape Cod (JBCC) has a wastewater collection, treatment and disposal system which provides service to the cantonment area on the base. The JBCC wastewater system is owned by the United States Air Force (USAF) and is operated by the Massachusetts Air National Guard (ANG) and serves approximately 3,500 users.

The JBCC collection system includes 11 pumping stations and approximately 36 miles of sewers. The collection system was constructed between the 1940s and the present. The current wastewater treatment facility (WWTF) is an extended aeration activated sludge facility with biological nitrogen removal and disinfection. The WWTF was constructed in 1996 and is located at the southeast edge of JBCC. WWTF effluent is pumped approximately 11 miles to a rapid infiltration basin (RIB) disposal system located at the northwest edge of JBCC. The locations of the wastewater system components are shown on **Figure ES-1**.

WWTF effluent must meet standards set forth in state water quality regulations. The WWTF effluent quality requirements are contained in a Groundwater Discharge Permit (GWDP) which is issued by the Massachusetts Department of Environmental Protection (DEP). The JBCC wastewater system is permitted to discharge an annual average flow of 360,000 gpd to the rapid infiltration basins. Current effluent flows are approximately 130,000 gpd and, therefore, unused treatment and disposal capacity is available.

JBCC also has a water production, treatment and distribution system which is owned by the USAF and operated by the ANG. The JBCC water system consists of two elevated water storage tanks and approximately 49 miles of buried water distribution mains. Water is supplied to the system from two sources: a gravel-packed well owned and operated by the JBCC (referred to as the "J-Well"); and a metered interconnection from the Upper Cape Regional Water Supply Cooperative (UCRWSC). The locations of the water system components are shown on **Figure ES-2**.

FIGURE ES-1
JBCC WASTEWATER SYSTEM

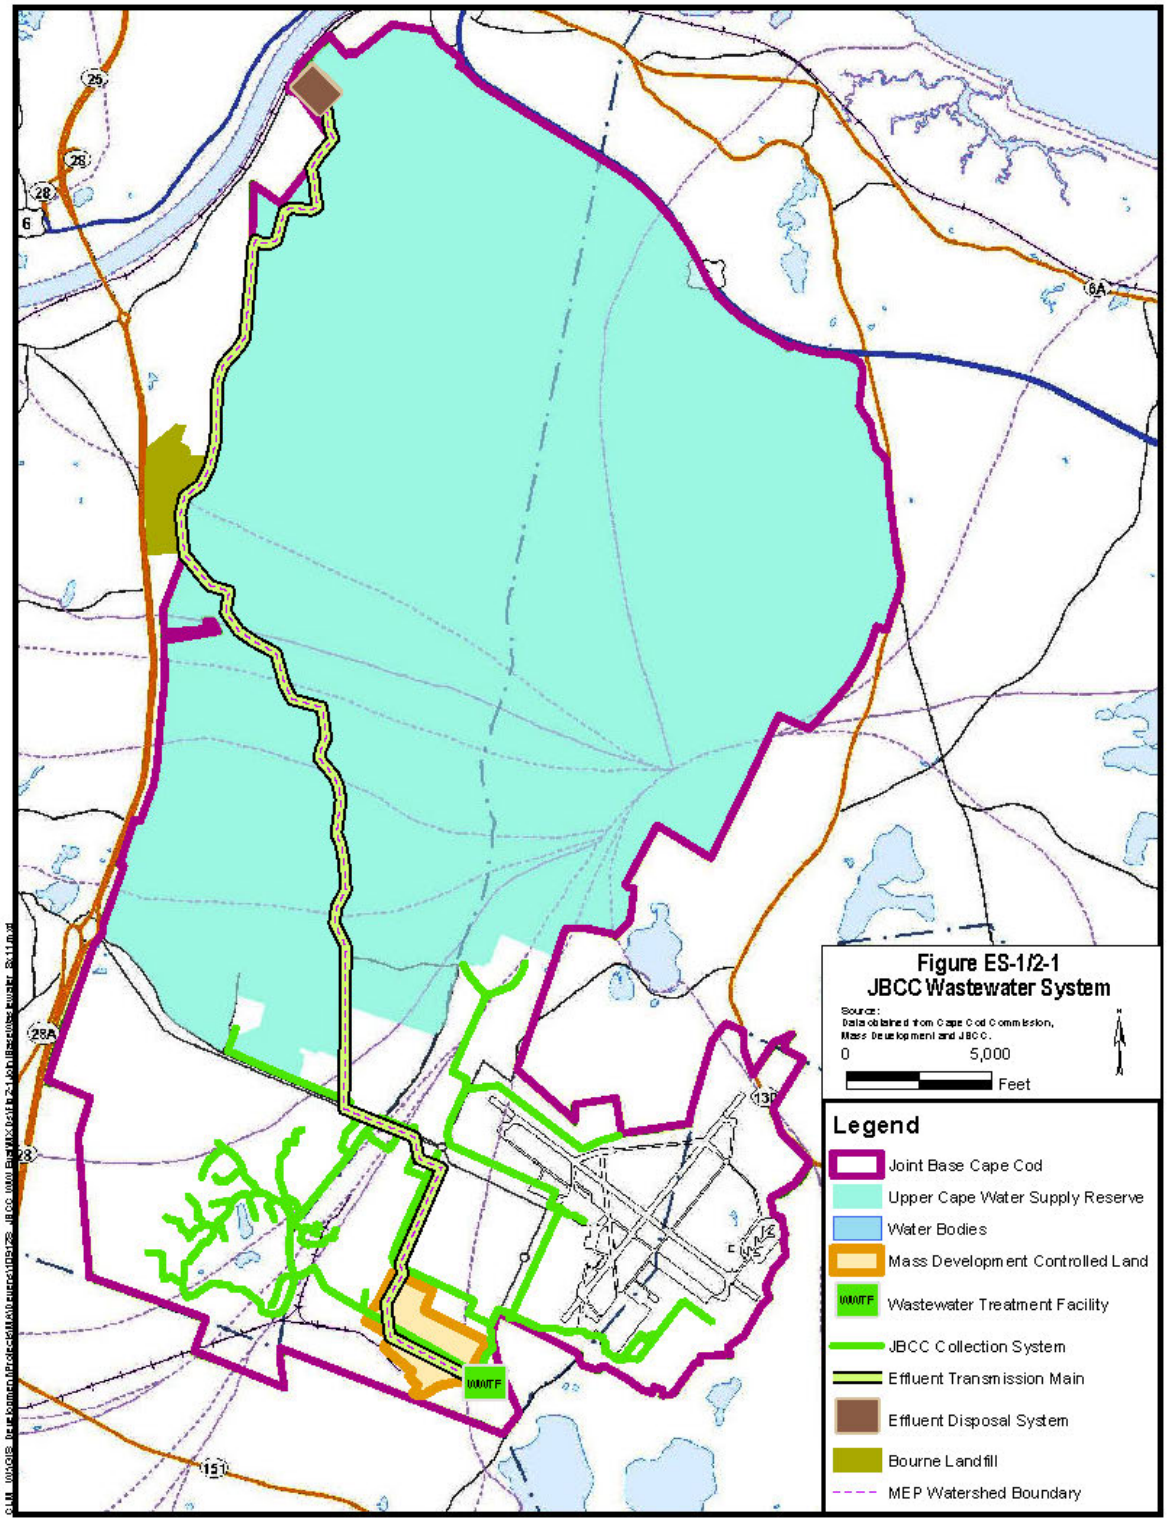

FIGURE ES-2
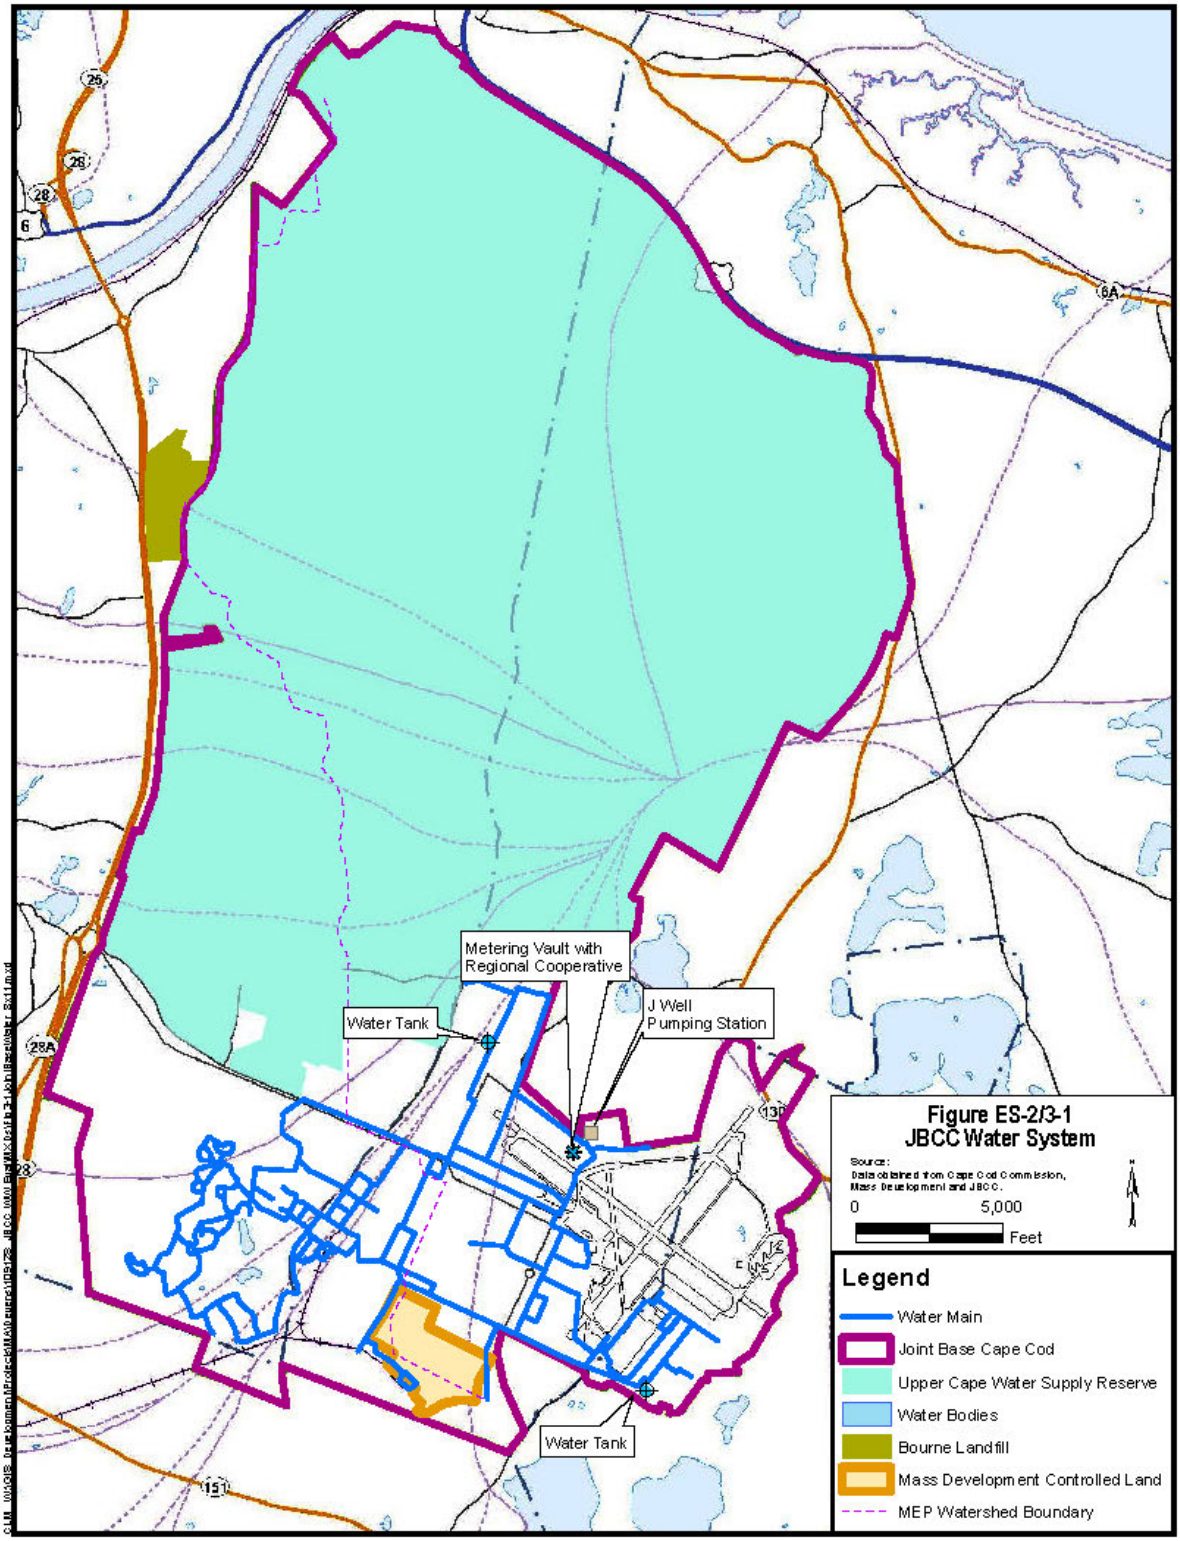
JBCC WATER SYSTEM



The Massachusetts Development Finance Agency (MassDevelopment) has been asked by the USAF and ANG to consider taking over the ownership and operation of the JBCC wastewater and water systems. Accordingly, MassDevelopment is interested in developing a full understanding of the financial implications and feasibility of ownership and management of the wastewater facilities and in developing a preliminary business case that evaluates the full range of cost and revenue options.

1.2 PROJECT PREMISE

1.2.1. Wastewater System

The primary purposes of this evaluation are to: develop an understanding of existing conditions; determine the financial implications of take-over; and position MassDevelopment for negotiations with the USAF and ANG. If MassDevelopment were to take over the wastewater system, it has two stated goals: provide for "military preservation" through rate stabilization; and provide service for other regional users. The JBCC is ideally suited for a potential regional use of the wastewater system by neighboring towns that could benefit the business case evaluation in a positive manner. We have identified the following potential alternatives for the wastewater system which should be evaluated:

1. **Existing WWTF with Minimal Capital Upgrades**

   This alternative will consist of utilizing the existing capacity to increase revenues and customer base by adding users for sewage (i.e., sanitary wastewater received by way of dedicated sanitary sewers), septage (i.e., trucked waste removed from residential and commercial septic tanks) and/or effluent disposal (i.e., treated wastewater from a separate wastewater treatment facility conveyed to the existing JBCC effluent disposal system). This alternative will explore "minimal capital upgrades".

2. **Existing WWTF with Moderate Capital Upgrades to Expand Capacity**

   This alternative will consist of a 50% capacity expansion to WWTF and RIBs while remaining in the existing fence lines. This alternative will involve more significant capital upgrades than Alternative 1 but will allow for greater revenues.

3. **New Regional WWTF**

   This alternative would consist of an "order of magnitude expansion" (i.e., 12 times the existing capacity) or replacement of the WWTF as outlined in the 2012 CH2M-Hill report.

4. **New Regional WWTF with Energy and/or Nutrient Recovery Capabilities**

   This alternative would expand upon Alternative 3 to include regional biosolids composting, regional energy recovery related to regional food waste (source separated organics) and/or regional nutrient recovery related to regional urine collection. These enhancements are consistent with the opportunities identified in the Cape Cod Commission's 2013 Joint Land Use Study Update report and 2014 Draft 208 Cape Cod Area-Wide Water Quality Management Plan.

The scope of our current project for the wastewater system (Delivery Order #12) includes only Alternative 1 and Alternative 2, as described above. We have structured our work so it can be expanded to address Alternatives 3 and 4 later.

1.2.2. Water System

If MassDevelopment were to take over the water system, it has one primary goal – provide for military preservation through rate stabilization. The JBCC water system could also represent a regional use opportunity; however, this is perhaps less likely than for the wastewater system. The scope of our current project for the water system (Delivery Order #11) includes evaluation of the system under a "status quo" arrangement (i.e., take ownership and operate the system as it is today, including the storage tanks, the J-well and the UCRWSC interconnection).

1.3 REPORT ORGANIZATION

This report is divided into the following sections: 1) Executive Summary; 2) Wastewater System; 3) Business Case Analysis for Wastewater Alternatives; 4) Assessment and Management of Risks; 5) Water System; 6) Conclusions and Recommendations; and 7) References. A list of commonly used acronyms and abbreviations is provided in **Table ES-1**.

TABLE ES-1
LIST OF COMMONLY USED ACRONYMS AND ABBREVIATIONS

ACEC	Area of Critical Environmental Concern
ANG	Air National Guard, Massachusetts (102nd Intelligence Wing)
BOD_5	Biochemical Oxygen Demand
CCC	Cape Cod Commission
Current	Covering the dates 2009 to 2013, applied to population, wastewater flow or nitrogen load conditions
CWMP	Comprehensive Wastewater Management Plan
D/B/O	Design/Build/Operate contract delivery method
DEIR	Draft Environmental Impact Report
DEP	Department of Environmental Protection (Massachusetts)
DRI	Developments of Regional Impact
EIR	Environmental Impact Report
EENF	Expanded Environmental Notification Form
EOEEA	Executive Office of Energy and Environmental Affairs (Massachusetts)
ESA	Environmentally Sensitive Area
FEIR	Final Environmental Impact Report
Future	Referring to population, wastewater flows or nitrogen loads, expected in the future
GIS	Geographic Information System
gpd	Gallons Per Day
gpd/sf	Gallons Per Day Per Square Foot
I/I	Infiltration and Inflow
ISO	Insurance Services Organization
HCF	Hundred Cubic Feet
Hp	Horsepower
JBCC	Joint Base Cape Cod (aka Massachusetts Military Reservations, Otis Air Force Base)
kg/day	Kilograms Per Day
kgal	Thousand Gallons
lb/yr	Pounds Per Year
MEP	Massachusetts Estuaries Project
MCL	Maximum Contaminant Level
MEPA	Massachusetts Environmental Policy Act
Mgal	Million gallons
Mgal/yr	Million gallons per year
mgd	Million gallons per day
mg/l	Milligrams per liter
MOU	Memorandum of Understanding
NHESP	Natural Heritage and Endangered Species Program
NPV	Net Present Value
O&M	Operations and Maintenance
RIB	Rapid Infiltration Basins
SCADA	Supervisory Control and Data Acquisition system (computer control system)
SEIR	Single Environmental Impact Report
SMAST	School of Marine Science and Technology, University of Massachusetts at Dartmouth
SRF	State Revolving Fund (administered by Massachusetts Department of Environmental Protection)
TKN	Total Kjeldahl Nitrogen
TMDL	Total Maximum Daily Load
TN	Total Nitrogen
TSS	Total Suspended Solids
USAF	United States Air Force
USEPA	United States Environmental Protection Agency
USGS	United States Geologic Survey
VFD	Variable Frequency Drive
VOC	Volatile Organic Compound
WWTF	Wastewater Treatment Facility

2 WASTEWATER SYSTEM

2.1 INTRODUCTION

This section of the report describes the existing wastewater system and summarizes current wastewater flows and loadings, compliance history, staffing levels, and condition assessment for the JBCC wastewater system. This section of the report also summarizes potential future flows and loadings, as well as the alternatives analysis and costs for potential wastewater system upgrades.

2.2 CURRENT CONDITIONS

2.2.1. Wastewater Flows and Loads

The wastewater flows and loads for the period 2008 to 2012 are summarized in **Table 2-1** (CH2M-Hill, 2012). We also requested and received data for the period January 2012 to April 2014. These data are also summarized in **Table 2-1**. Based on this information, the WWTF is operating at just under 50% of its design capacity. **Figure 2-1** and **Figure 2-2** show daily effluent flows and daily effluent nitrogen concentrations, respectively.

2.2.2. Overall System

The existing JBCC wastewater system provides service for on-base facilities. It is currently owned by the United States Air Force (USAF) and is currently operated and maintained by the Massachusetts Air National Guard 102nd Intelligence Wing (ANG). The major components of the existing wastewater treatment system are summarized in **Table 2-2**. A detailed listing of the system components is provided in Appendix A of the 2012 CH2M-Hill report.

The WWTF and all of the collection system are located within the Cantonment Area, which comprises 25% of JBCC. Most of the effluent forcemain and the entire effluent disposal system are located in the Upper Cape Water Supply Reserve, which comprises the northerly 75% of JBCC. The existing JBCC wastewater system is shown on **Figure ES-1**.

TABLE 2-1
CURRENT WWTF FLOWS AND LOADINGS

Parameter	Condition	Design Rating	Permit Value	Current 2008 to 2012	Current 2012 to 2014
Flow (gpd)	Annual Average	300,000	360,000 (1)	143,000	131,000
	Maximum Month	430,000	-	248,500	210,000
	Maximum Day	800,000	840,000	555,600	390,000
	Peak Hourly	1,380,000	-	-	-
BOD Load (lb/day)	Annual Average	690	-	337	-
	Maximum Month	990	-	548	-
	Maximum Week	1840	-	948	-
TSS Load (lb/day)	Annual Average	550	-	272	-
	Maximum Month	790	-	453	-
	Maximum Week	1470	-	884	-
TKN Load (lb/day)	Annual Average	125	-	60	-
	Maximum Month	180	-	104	-
	Maximum Week	335	-	233	-
Ammonia Load (lb/day)	Annual Average	90	-	43	-
	Maximum Month	125	-	76	-
	Maximum Week	235	-	163	-

Note: 1) 12-month rolling average daily flow.

TABLE 2-2
WASTEWATER SYSTEM COMPONENTS

Component	Quantity
Collection & Conveyance	161,000 linear feet sewers, 595 manholes
Pump Stations	11
Wastewater Treatment Facility	300,000 gpd (design); 360,000 gpd (permit)
Effluent Forcemain	55,280 linear feet
Rapid Infiltration Disposal Beds (RIBs)	4 cells, 6 acres
Monitoring Wells (for RIBs):	7
Composting Facilities (abandoned)	25,290 square feet

FIGURE 2-1
JBCC WWTF EFFLUENT FLOW

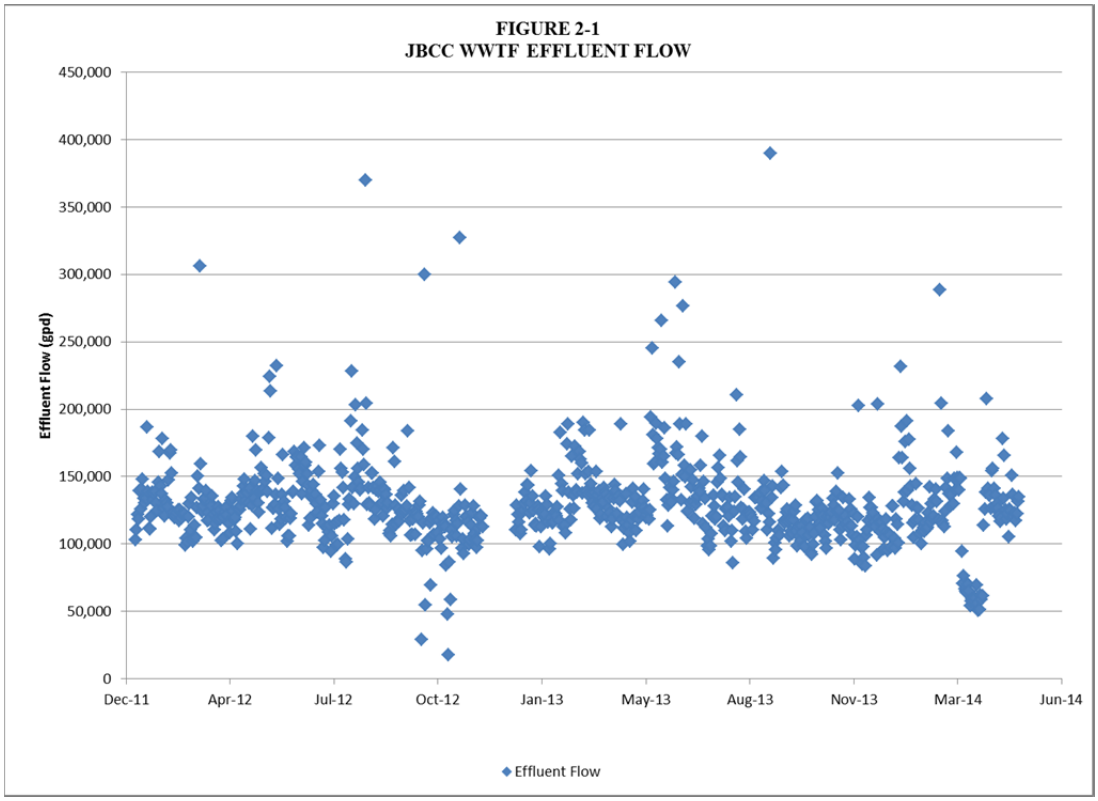


FIGURE 2-2
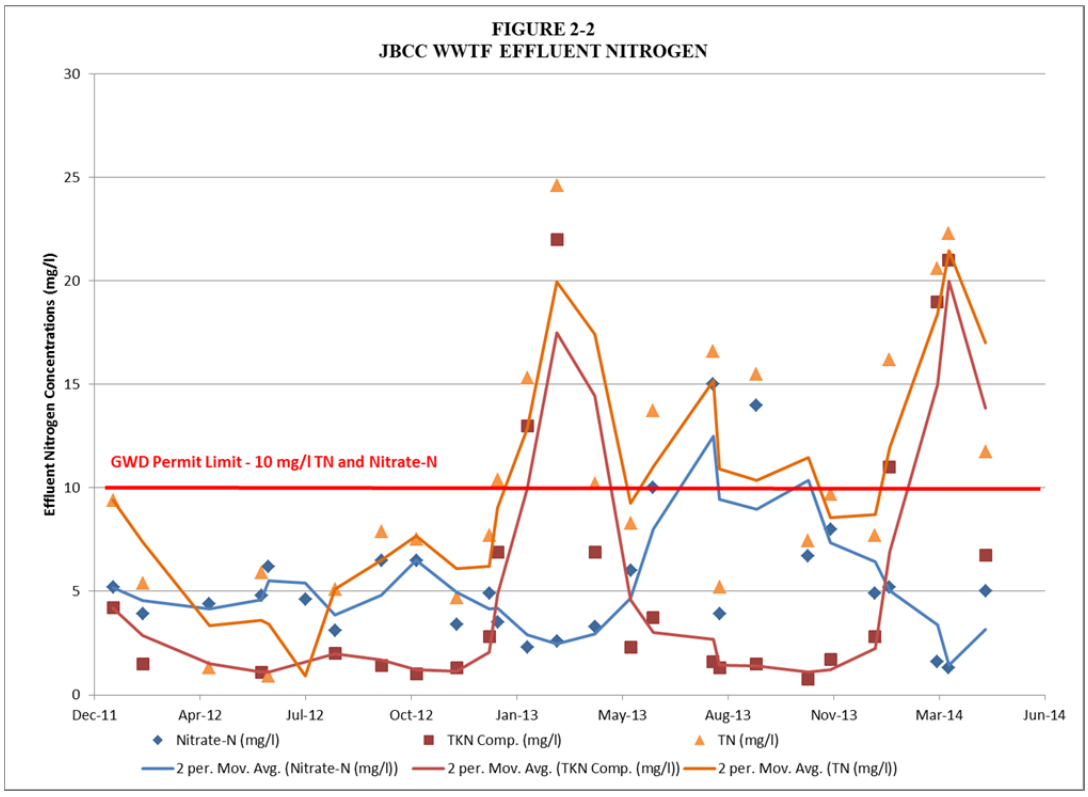
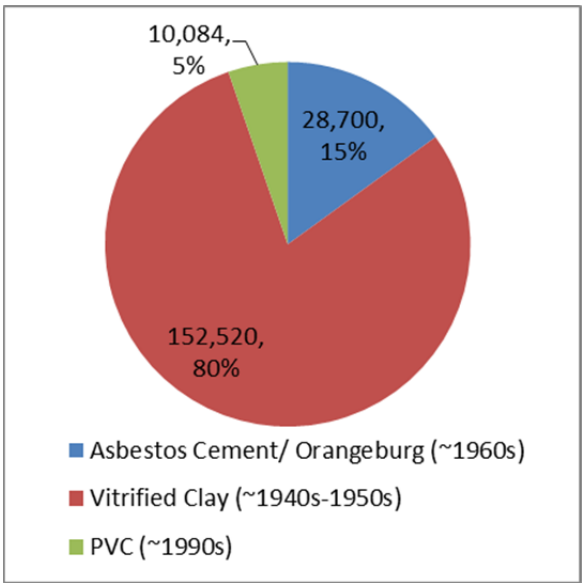
JBCC WWTF EFFLUENT NITROGEN



2.2.3. Collection System

The collection system was built when there were 70,000 users on-site; whereas, there are currently approximately 3,500 users (JBCC Base Population Survey, 2009). The collection system includes approximately 36 miles of sewers ranging in size from 6-inch to 24-inch diameter including several pipe materials. The asbestos cement and orangeburg pipe materials will exceed their design lives in the next 10 years. A summary of the pipe types and lengths is provided in the inset figure.



Length of Pipe (feet)

2.2.4. Wastewater Treatment Facility

The WWTF is an extended aeration activated sludge facility (biological nitrogen removal) with disinfection that was constructed in 1996. The WWTF design capacity is 300,000 gpd (annual average) with a design maximum day flow of 800,000 gpd.

Major unit processes at the WWTF include:

- Preliminary Treatment (screening and grit removal)
- Advanced secondary treatment (biological nutrient removal)
- Disinfection
- Effluent Pumping
- Sludge Holding and Aeration
- Sludge Decanting
- Biosolids hauling (for off-site processing and disposal)

The WWTF equipment is in good condition; however, upgrades will be needed to address regulatory compliance issues as well as to maintain existing reliability.

2.2.5. Effluent Forcemain

The existing effluent forcemain is a 12-inch diameter ductile iron pipe that runs from the WWTF, through the Reserve, to the Rapid Infiltration Basins. The forcemain is shown on the design drawings entitled "Effluent Forcemain and Infiltration Basins" (CDM/SAIC, 1993). The forcemain is hydraulically complex and has approximately 20 air and/or vacuum relief valves. The operators reported capacity limitations when more than one effluent pump is running (i.e., overflow at the static head manhole located at Frank Perkins Road, near pipeline station 245+00, about 45% of the way from the WWTF to the RIBs). This situation requires further evaluation.

2.2.6. Rapid Infiltration Basins

The existing effluent disposal facility consists of four rapid infiltration basins (RIBs), with a total surface area of 259,160 square feet. The RIBs were constructed on the basis of design drawings entitled "Effluent Forcemain and Infiltration Basins" (CDM/SAIC, 1993) as well as a *Hydrogeologic Investigation and Design Effluent Infiltration Basins* technical memorandum (CDM/SAIC, 1993). The operators reported that the RIBs work very well and the only significant concern is the vegetation growth with the RIBs. As described later in this section, inflow in the collection system limits the available effluent disposal capacity. This situation warrants further evaluation and potentially re-rating of the RIBs.

2.2.7. Groundwater Discharge Permit Requirements

The WWTF effluent quality requirements are contained in a Groundwater Discharge Permit (GWDP) which is issued by the Massachusetts Department of Environmental Protection (DEP). The GWDP (Application/Permit No. 41-3) allows for disposal of suitable quality effluent up to 360,000 gpd on a 12-month rolling average basis and up to a maximum of 840,000 gpd on any given day (so-called "maximum day flow"). It is important to note that disposal capacity provided under the GWDP is greater than the design capacity indicated in WWTF design documentation. The GWDP is included in Appendix A and its requirements for the WWTF effluent are summarized in **Table 2-3**. The GWDP requirements for groundwater monitoring at the RIB site are summarized in **Table 2-4**.

TABLE 2-3
WWTF EFFLUENT LIMITS AND MONITORING REQUIREMENTS

Parameter	Discharge Limitation	Minimum Frequency
Flow, 12-month moving average	360,000 gpd	Daily
Flow, maximum day	840,000 gpd	Daily
Oil and grease	15 mg/l	Monthly
Total Suspended Solids (TSS)	30 mg/l	Monthly
Total Nitrogen (NO2-N + NO3-N + TKN)	10 mg/l	Monthly
Nitrate-Nitrogen (NO3-N)	10 mg/l	Monthly
Biochemical Oxygen Demand, 5-day at 20°C (BOD_5)	30 mg/l	Monthly
Fecal Coliform	200 colonies/ 100 ml	Monthly
pH	6.5 to 8.5	Daily
Total Solids	Report	Monthly
Total Phosphorus (as P)	Report	Monthly
Orthophosphate (as P)	Report	Monthly
Volatile Organic Compounds	Report	Monthly

TABLE 2-4
GROUNDWATER MONITORING REQUIREMENTS

Parameter	Discharge Limitation	Minimum Frequency
Static Water Level	Report	Monthly
Specific Conductance	Report	Monthly
pH	Report	Monthly
Total Nitrogen (NO2-N + NO3-N + TKN)	Report	Quarterly
Nitrate-Nitrogen (NO3-N)	Report	Quarterly
Total Phosphorus (as P)	Report	Quarterly
Orthophosphate (as P)	Report	Quarterly
Volatile Organic Compounds	Report	Quarterly

2.2.8. Compliance History

During our site tour on June 4, 2014, the WWTF operators identified some operational concerns related to highly variable influent flows (due to base activities), inflow-related wet weather peak flows, and winter denitrification. A review of the current data provided by JBCC indicates that GWDP limits for nitrate and/or total nitrogen were exceeded in 11 of the last 27 months between January 2012 and April 2014. Capital improvements are warranted to improve performance.

2.2.9. Staffing

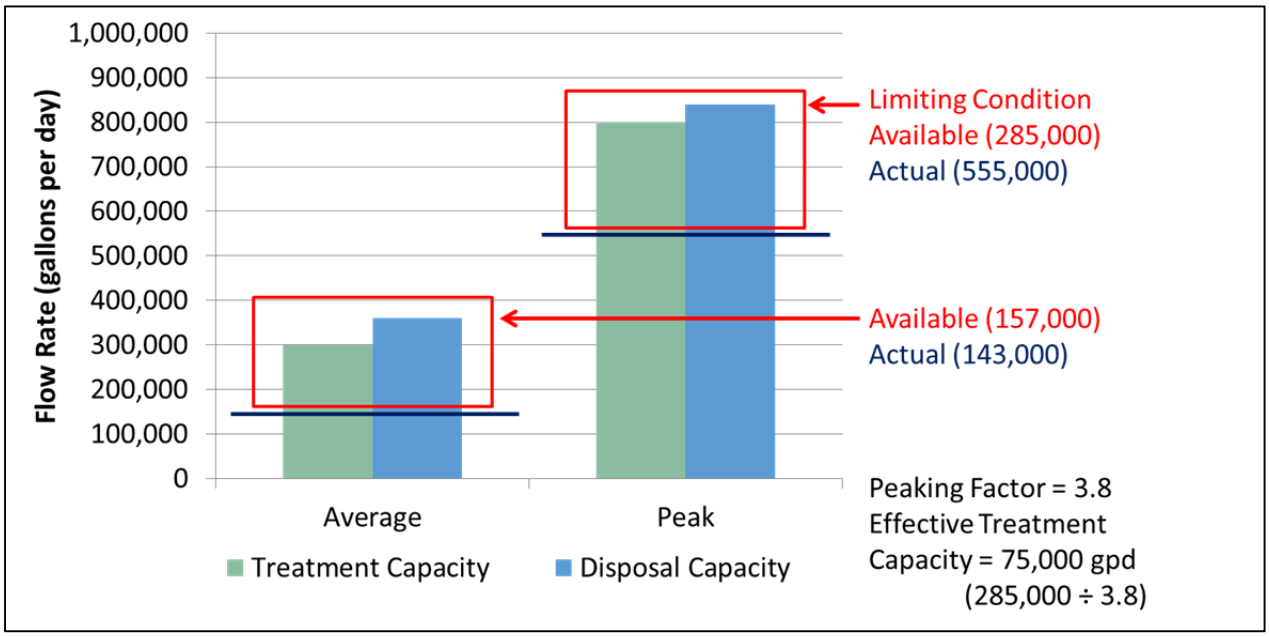
The GWDP permit rates the WWTF as a Grade 5 facility in accordance with 257 CMR 2.00 and requires that the existing WWTF be overseen by a Grade 5 (or higher) operator with a backup Grade 5 operator available. JBCC reported that there are 5 operators that are shared between the water and wastewater systems. Based on our initial assessment, this appears appropriate for the WWTF and the water wells but appears to be understaffed for the wastewater collection system and the water distribution system.

2.2.10. Estimate of Existing Available Capacity

Based on the WWTF design capacity and the 2008 to 2012 flows and loads, the WWTF has approximately **157,000 gpd (annual average)** of residual capacity which can be made available to neighboring communities or users on the base.

On an annual average basis, the effluent disposal system has approximately 157,000 gpd of additional capacity. On a peak day basis (due to the impacts of inflow), the effluent disposal system has approximately 285,000 gpd of additional capacity. Given that the existing peaking factor for peak to average flows is 3.8:1 (again, due primarily to the impacts of inflow), the *effective capacity* is approximately **75,000 gpd (annual average basis)**. It is important to note this *effective capacity* is less than that available at the WWTF. Without inflow control, available treatment capacity will go unused due to the limitations inherent in the GWDP. The capacity and effective capacity is illustrated on **Figure 2-3**.

FIGURE 2-3
ESTIMATE OF EXISTING AVAILABLE CAPACITY



This existing available capacity can be made available to neighboring communities or to new users which may be located on JBCC. From a potential revenue perspective, it is very important to maximize the available capacity. This available capacity can be maximized by one or more of the following methods:

- Aggressively investigating and removing collection system inflow sources;
- Securing customers with low wastewater flow "peaking factors" (i.e., customers with a peak flow that is similar to the average flow);
- Providing influent flow equalization at the WWTF;
- Addressing the effluent forcemain capacity limitation; and/or
- Increasing the capacity of the RIBs by re-rating the site and revising the GWDP with DEP review and approval.

2.3 FUTURE CONDITIONS

The 2012 CH2M-Hill report identified future flows from various military users as well as adjacent municipalities. This section summarizes the future flows used in this analysis.

2.3.1. Future Flows for Existing Users (Sewage)

There are 10 military and non-military users on the existing system with an estimated wastewater flow of 140,000 gpd (CH2M-Hill, 2012). Future flow from military and non-military users was estimated to be 7,000 gpd (CH2M-Hill, 2012). This future flow was utilized herein.

2.3.2. Future Flows for MassDevelopment (Sewage)

MassDevelopment indicated that it has the ability to develop up to 250 acres of land at the southern end of JBCC (in the vicinity of the WWTF) and has provided development goals for this land as follows: Warehousing/Storage Facility – estimated 24 employees (daytime only), located near the WWTF; and Cape Cod Community College Extension Facility – estimated 35 students and faculty (daytime only), located near the airfield and fire station. Based on Title 5 (310 CMR 15.203), this amounts to approximately 880 gpd (i.e., 15 gpd/person for Warehouse/ Dry Storage Space without Cafeteria as well as 15 gpd/person for Secondary/Middle School with cafeteria but no gymnasium or showers). It was agreed that an allowance of 5,000 gpd for MassDevelopment would be used in the analysis moving forward.

2.3.3. Future Flows for Neighboring Municipalities (Sewage)

Neighboring municipalities identified the following wastewater management needs (annual average flows) which could potentially be served by JBCC (CH2M-Hill, 2012):

- Bourne: If capacity were available, potential future flows to JBCC – 1,836,000 gpd.
- Sandwich: If capacity were available, potential future flows to JBCC – 1,080,000 gpd.
- Mashpee: If capacity were available, potential future flows to JBCC – 816,000 gpd.

Bourne and Sandwich have not completed additional wastewater management planning since 2012; however, Mashpee has refined its wastewater management planning. Mashpee is currently projecting potential future flows to JBCC at 200,000 gpd (GHD, 2014). Wastewater flows from

Mashpee should be considered in the near-term future of the JBCC wastewater system; whereas, wastewater flows from Bourne and Sandwich should be considered in the longer-term future given the status of their respectively planning efforts.

2.3.4. Future Flows for Regional Septage

Septage is trucked waste which is periodically removed from residential and commercial septic tanks. There have been several previous estimates of septage volumes produced on Cape Cod, both at present and in the future. As a part of this evaluation, we updated estimates of current and future septage volumes. These prior and current estimates are summarized in **Table 2-5**.

Currently about 8 Mgal/yr is received at the Falmouth WWTF, and perhaps 5 to 10 Mgal/yr is hauled off-Cape. Falmouth may benefit from sending its septage to JBCC, because it would reduce the effluent nitrogen loading to West Falmouth Harbor (by the equivalent of 20,000 gpd at the typical effluent nitrogen concentration of 3 to 4 mg/l) and make capacity available for influent flows from areas of Falmouth needing sewers.

Based on this evaluation, we recommend that the financial planning for JBCC wastewater facilities consider the potential receipt of up to 20 to 25 Mgal/yr of septage (as well as sludge from small-scale, satellite wastewater treatment plants with current revenue of up to $2.0 to $2.5 million per year.

TABLE 2-5
ESTIMATES OF REGIONAL SEPTAGE VOLUMES

Study	Estimate of Current Annual Septage Volumes	Estimate of Future Annual Septage Volumes
Tri-Town Facility Evaluation Wright-Pierce, 2005	59 Mgal	87 to 89 Mgal
Orleans CWMP Wright-Pierce, 2010	54 Mgal	-
Regional Wastewater Mgmt Plan Cape Cod Commission, 2012	-	53 to 78 Mgal
JBCC Evaluation, Wright-Pierce, 2014 Total (See Note 1) Less than 10 miles to JBCC Less than 15 miles to JBCC	 50 to 65 Mgal 14 to 18 Mgal (28%) 18 to 23 Mgal (36%)	 30 to 40 Mgal 8 to 12 Mgal (28%) 10 to 14 Mgal (36%)

Notes:
1) Estimates exclude the 1 to 2 Mgal/year from the 50 satellite WWTFs on Cape Cod, 22 of which are in Bourne, Falmouth, Sandwich and Mashpee. Estimates exclude grease volumes.

2.3.5. Future Flows for Effluent Disposal

Two municipalities have expressed interest in discharging effluent to the JBCC disposal system (i.e., connecting to the effluent forcemain and not to the WWTF). Each is summarized below.

- Bourne has expressed interest in discharging treated landfill leachate. Currently Bourne collects the leachate in a holding tank and trucks it off-Cape for treatment and disposal. Published reports indicate that the annual volume hauled by Bourne has varied from 6.0 to 16.0 Mgal/year (Joyce Engineering, 2009; Commonwealth Resource Management Corporation, 2011). The preliminary proposal is for Bourne to construct a treatment facility and connect to the JBCC effluent forcemain at an average daily flow rate of 40,000 gpd (14.6 Mgal/year) (CH2M-Hill, 2012).
- Falmouth has expressed interest in discharging treated municipal wastewater. Currently Falmouth discharges effluent to rapid infiltration beds located in the West Falmouth Harbor watershed. This watershed currently exceeds its nitrogen threshold and, therefore, nitrogen must be removed from the watershed. The preliminary proposal is for Falmouth to construct an effluent forcemain and connect to the JBCC effluent forcemain at an average daily flow rate of 200,000 gpd (CH2M-Hill, 2012).

2.3.6. Future Permit Limits

The current GWDP is focused primarily on addressing conventional parameters (BOD, TSS, bacteria) as well as nutrients (nitrogen, phosphorus). Over time, additional parameter or more stringent effluent limits may be imposed.

- Nitrogen – DEP has not indicated any intention to revise the JBCC nitrogen limits at this time. There is no Total Maximum Daily Load (TMDL) Study completed or planned because the effluent disposal site is not located in a nitrogen sensitive watershed. Given the location of the discharge, the imposition of a more stringent nitrogen limit is unlikely.
- Phosphorus – DEP has not indicated any intention to add a phosphorus limit at this time. Given the location of the discharge, the imposition of a phosphorus limit is very unlikely.
- Compounds of emerging concern (CECs) – CECs encompass a wide variety of compounds including endocrine disrupting compounds, pharmaceuticals, flame

retardants, hormones, industrial solvents and surfactants, metals, pesticides, and personal care products. CECs have been found in wastewater for decades; however, they have recently reached the forefront of regulatory and public concern, and there is currently a great deal of research on CECs. One of the difficulties associated with addressing this topic is the large number and wide array of substances that can be classified as CECs. EPA and DEP have not established effluent standards for CECs to date, and have not indicated any intention to regulate CECs in the near term. Given that the location of the discharge is outside water supply recharge areas, the imposition of CEC limits is very unlikely.

While capital upgrades would be required if the GWDP requirements were made more stringent, this eventuality appears unlikely within a 10 to 20 year timeframe.

2.4 ALTERNATIVES ANALYSIS

Recalling the Project Premise described in Section 1, the purpose of this evaluation is to estimate the costs and revenues associated with Alternative 1 (use of existing capacity) and Alternative 2 (50% capacity expansion). Based on the estimated future flows available from each wastewater category (i.e., sewage, septage, effluent), it is apparent that the future wastewater management needs in the Upper Cape region easily exceed the capacity available at the existing JBCC wastewater system and may also exceed the capacity available with a 50% expansion.

In order to provide a framework for the business case analysis (**Section 3**), we have developed eight upgrade alternatives for the JBCC wastewater facilities, as follows:

- Alternative 1A – Baseline Improvements
- Alternative 1B – Baseline Improvements plus Septage Receiving
- Alternative 1C – Baseline Improvements plus Effluent Disposal
- Alternative 1D – Baseline Improvements plus Septage and Effluent Disposal
- Alternative 2A – Expansion
- Alternative 2B – Expansion plus Septage Receiving
- Alternative 2C – Expansion plus Effluent Disposal

- Alternative 2D – Expansion plus Septage and Effluent Disposal

We have utilized the future flows, organized by alternative and by wastewater category, indicated on **Table 2-6**. Each of the alternatives is described below.

TABLE 2-6
FUTURE FLOWS FOR ALTERNATIVES ANALYSIS

	Existing	Additional			Future
	Sewage (gpd)	Sewage (gpd)	Septage (gpd)	Effluent (gpd)	Total (gpd)
Alternative 1A	140,000	160,000	0	0	300,000
Alternative 1B	140,000	12,000	20,000	0	172,000
Alternative 1C	140,000	160,000	0	40,000	340,000
Alternative 1D	140,000	12,000	20,000	40,000	212,000
Alternative 2A	140,000	310,000	0	0	450,000
Alternative 2B	140,000	160,000	20,000	0	320,000
Alternative 2C	140,000	310,000	0	40,000	490,000
Alternative 2D	140,000	160,000	20,000	40,000	360,000

Notes:
1. Growth allowance for existing military and non-military users is from CH2M-Hill, 2012.
2. Growth allowance for MassDevelopment is described herein.
3. Septage allowance is based on treatment and GWDP. Septage revenues are based on 15,000 gpd annual average (5.5Mgal/year).
4. Effluent allowance is based on Bourne landfill leachate effluent (14.6Mgal/year).

2.4.1.1 Alternative 1A – Baseline Improvements (Sewage Only)

This alternative consists of constructing minimal upgrades to address permit compliance, increase peak flow capacity and reduce O&M costs related to liquid sludge disposal. These upgrades include:

- Add an off-line influent equalization tank and a pump station to help with peak flow management. Set equalization volume at 100,000 gallons (note: this is approximately the same size as each anoxic basin).
- Add a small supplemental carbon system including 500-gallon storage tank, one chemical feed pump, instrumentation interface with SCADA and electrical feeds.

- Add a rotary disc or drum thickener over the existing Sludge Storage Tanks and enclose it in a small building. Automate sludge wasting and polymer feed system to pre-thicken waste sludge prior to storage.
- Replace existing sludge feed pumps (progressing cavity) with higher rate sludge feed pumps (rotary lobe) to convey thickened sludge to a tanker truck at high rate (say 200 gpm) to allow for shorter truck fill times. Add new truck fill piping with quick-connect to building exterior.
- Upgrade the effluent forcemain (i.e., increase the pipe from 8"-inch to 18-inch from Static Head Structure No. 1 to Hydraulic Distribution Structure, replace all existing air/vacuum release valves, add a surge tank at the Frank Perkins Road Static Head Structure).

This scenario would allow for approximately 160,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment as well as most of the needs identified by Mashpee.

2.4.1.2 Alternative 1B – Baseline Improvements (Sewage and Septage)

This alternative consists of constructing minimal upgrades to address permit compliance, increase peak flow capacity and reduce O&M costs. These upgrades include:

- All upgrades identified in Alternative 1A.
- Construct additional upgrades to allow for up to 20,000 gpd septage capacity, including: new mechanical septage screening unit (400-gpm, outdoor rated, insulated); new septage storage tank (40,000-gallon tank) with decant provisions; new septage aeration system (coarse bubble diffusers and 2 blowers); new piping to connect from septage storage tank to sludge feed pumps (to load a liquid tanker truck); and decant pump station (20,000-gallon storage volume) with force main to headworks.

This scenario would allow for approximately 12,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment. Additional treatment capacity would be used for septage treatment.

2.4.1.3 Alternative 1C – Baseline Improvements (Sewage and Effluent)

This alternative consists of constructing minimal upgrades to address permit compliance, increase peak flow capacity and reduce O&M costs. These upgrades include:

- All upgrades identified in Alternative 1A.
- Receive Bourne landfill leachate effluent via a forcemain connection to the existing effluent forcemain. It is assumed that there are no capital improvements required by MassDevelopment/JBCC for the physical connection.
- Re-rate the RIBs to allow for additional capacity.

This scenario would allow for approximately 160,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment as well as most of the needs identified by Mashpee. Additional disposal capacity would be used for the effluent disposal needs of Bourne.

2.4.1.4 Alternative 1D – Baseline Improvements (Sewage, Septage and Effluent)

This alternative consists of constructing minimal upgrades to address permit compliance, increase peak flow capacity and reduce O&M costs. These upgrades include:

- All upgrades identified in Alternative 1A.
- Construct additional upgrades to allow for up to 20,000 gpd septage capacity, including: new mechanical septage screening unit (400-gpm, outdoor rated, insulated); new septage storage tank (40,000-gallon tank) with decant provisions; new septage aeration system (coarse bubble diffusers and 2 blowers); new piping to connect from septage storage tank to sludge feed pumps (to load a liquid tanker truck); and decant pump station (20,000-gallon storage volume) with force main to headworks.
- Receive Bourne landfill leachate effluent via a forcemain connection to the existing effluent forcemain. It is assumed that there are no capital improvements required by MassDevelopment/JBCC for the physical connection.
- Re-rate the RIBs to allow for additional capacity.

This scenario would allow for approximately 12,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment. Additional disposal capacity would be used for the effluent disposal needs of Bourne.

2.4.1.5 Alternative 2A – Expansion (Sewage Only)

This alternative consists of comprehensive upgrades to address permit compliance, increase peak flow capacity, reduce O&M costs and expand the WWTF capacity. These upgrades include:

- All upgrades identified in Alternative 1A.
- Construct additional upgrades to allow for additional overall treatment capacity within the fencelines of the WWTF and Effluent Disposal sites, including: new third Carrousel oxidation ditch; new third secondary clarifier; and new fourth sludge storage tank.
- Upgrade the effluent forcemain (i.e., increase the pipe from 8"-inch to 18-inch from Static Head Structure No. 1 to Hydraulic Distribution Structure, replace all existing air/vacuum release valves, add a surge tank at the Frank Perkins Road Static Head Structure) and re-rate/upgrade the effluent disposal beds to gain additional capacity (i.e., Hydrogeologic testing to re-rate the RIBs, add segmentation of RIBs within the existing footprint, add wicks).

This scenario would allow for approximately 310,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military, MassDevelopment and Mashpee. Additional capacity could be utilized for other municipalities.

2.4.1.6 Alternative 2B – Expansion (Sewage and Septage)

This alternative consists of comprehensive upgrades to address permit compliance, increase peak flow capacity, reduce O&M costs and expand the WWTF capacity. These upgrades include:

- All upgrades identified in Alternative 2A and in Alternative 1B.

This scenario would allow for approximately 160,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment as well as

most of the needs identified by Mashpee. Additional treatment capacity would be used for septage treatment.

2.4.1.7 Alternative 2C – Expansion (Sewage and Effluent)

This alternative consists of comprehensive upgrades to address permit compliance, increase peak flow capacity, reduce O&M costs and expand the WWTF capacity. These upgrades include:

- All upgrades identified in Alternative 2A and in Alternative 1C.

This scenario would allow for approximately 310,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military, MassDevelopment and Mashpee. Additional capacity could be utilized for other municipalities. Additional disposal capacity would be used for the effluent disposal needs of Bourne.

2.4.1.8 Alternative 2D – Expansion (Sewage, Septage and Effluent)

This alternative consists of comprehensive upgrades to address permit compliance, increase peak flow capacity, reduce O&M costs and expand the WWTF capacity. These upgrades include:

- All upgrades identified in Alternative 2A and in Alternative 1D.

This scenario would allow for approximately 160,000 gpd from new sewer users to the WWTF. This would address the needs of JBCC military/non-military and MassDevelopment as well as most of the needs identified by Mashpee. Additional treatment capacity would be used for septage treatment and for the effluent disposal needs of Bourne.

2.5 EXISTING ANNUAL O&M COSTS

The existing wastewater O&M costs for the past 5 years are summarized in **Table 2-7**. This summary was prepared based on information provided by JBCC.

TABLE 2-7
EXISTING ANNUAL O&M BUDGETS

Budget Item	2009	2010	2011	2012	2013
Chemicals (Hypochlorite, Bisulfite)	$25,851	$6,710	$22,451	$20,719	$22,905
Enzymes	$6,495	$130	$856	$228	$571
Biosolids Disposal	$24,792	$26,830	$30,000	$38,480	$22,000
Collection System (Degreasers)	$129	$0	$0	$0	$0
Lab Testing and Supplies	$19,882	$1,644	$3,273	$1,301	$1,301
Supplies and Shop Stock	$10,632	$42,709	$40,845	$62,187	$55,598
Parts and Equipment	$64,961	$25,987	$13,105	$0	$26,393
Service Contracts	$0	$12,573	$24,597	$35,142	$32,769
Projects (Sustainment, Repair, Modernization)	$0	$33,832	$0	$0	$39,655
Natural Gas	$5,739	$6,514	$7,776	$5,830	$7,615
Electricity	$85,733	$101,315	$105,827	$102,050	$99,263
Total Annual Costs (excl. Labor)	**$244,213**	**$258,244**	**$248,729**	**$265,937**	**$308,070**
Annual Volume Treated (Mgal)	54.82	52.04	51.11	48.64	47.68
Unit Cost (excl. Labor)	$4.50	$4.96	$4.87	$5.47	$6.46
Annual Labor with Benefits	-	-	-	$342,300	$356,000
Est. Labor for Wastewater (66%)	-	-	-	$225,920	$234,960
Total Annual Costs (incl. Labor)	-	-	-	**$491,860**	**$543,030**
Est. Unit Cost (incl. Labor)	-	-	-	$10.11	$11.39
Charges to Typ. Military User	-	-	-	$5.47	$6.46
Charges to Typ. Non-Military User	-	-	-	$9.24	$10.57

Notes
1. Annual budget data provided by JBCC. Typical user service agreements provided by JBCC
2. Biosolids hauling and disposal cost is $0.11/gallon per current contract according to JBCC.
3. Annual labor with fringe benefits for 2013 was provided by JBCC.
4. Unit costs are per thousand gallons of wastewater.
5. Existing labor allocation between wastewater and water utilities was estimated at 66% and 34%, respectively.

2.6 ESTIMATED COSTS FOR UPGRADES

Regardless of which alternative is selected, MassDevelopment will be faced with costs in two categories. The first category is "capital cost", which include the cost to design and construct the needed facilities. The second category is "operation and maintenance costs", which include the on-going annual expenses to run the facilities.

2.6.1. Capital Costs

The planning-level costs were developed using standard cost estimating procedures consistent with industry standards utilizing conceptual layouts, unit cost information, and planning-level cost curves, as necessary. Total project capital costs include allowances of 40% of the estimated construction costs to account for construction contingency, design and construction engineering, permitting, as well as financing, administrative and legal expenses. Many factors arise during final design (e.g. foundation conditions, owner-selected features and amenities, code issues, etc.) that cannot be definitively identified and estimated at this time. These factors are typically covered by the allowances described above; however, this allowance may not be adequate for all circumstances. The project cost information presented herein is in current dollars and is based on ENR Construction Cost Index 9870 (October 2014). Planning-level project costs have been prepared for the various alternatives are presented in **Table 2-8**.

The costs presented herein do not include costs for new sewer users or new effluent disposal users to plan, design or construct infrastructure to convey their flows to the JBCC wastewater system. It is assumed that the new users will be responsible for these costs.

2.6.2. Annual Operating and Maintenance Costs

Annual O&M costs were prepared for each of the alternatives based on the estimated increase and decrease in the existing WWTF budget line items. The current budget and the current flows and loads were considered the baseline. Future staffing requirements have been estimated using criteria established by EPA Publication MO-1 ("Estimated Staffing for Municipal Wastewater Treatment Facilities"). The estimated annual O&M costs as well as the anticipated additional staff are presented in **Table 2-9**.

TABLE 2-8
ESTIMATED CAPITAL COSTS FOR ALTERNATIVES

	Construction Cost	Project Cost
Alternative 1A	$2,350,000	$3,290,000
Alternative 1B	$2,790,000	$3,910,000
Alternative 1C	$2,350,000	$3,290,000
Alternative 1D	$2,790,000	$3,910,000
Alternative 2A	$6,510,000	$9,110,000
Alternative 2B	$7,590,000	$10,630,000
Alternative 2C	$6,510,000	$9,110,000
Alternative 2D	$7,590,000	$10,630,000

Notes:
1. ENR CCI 9870 (October 2014)
2. Project costs include a planning-level allowance of 40% of construction cost to account for contingency, technical services, legal and administrative costs.

TABLE 2-9
ESTIMATED ANNUAL O&M COSTS FOR ALTERNATIVES

	Annual O&M Cost	New Staff
Alternative 1A	$680,000	1
Alternative 1B	$670,000	1
Alternative 1C	$690,000	1
Alternative 1D	$670,000	1
Alternative 2A	$930,000	2
Alternative 2B	$940,000	2
Alternative 2C	$930,000	2
Alternative 2D	$940,000	2

Notes:
1. ENR CCI 9870 (October 2014)
2. Annual O&M Costs exclude MassDevelopment administrative costs, contract operator overhead, reserve accounts and debt service.

These estimates are based on the following assumptions:

- Utility rates as well as chemical and biosolids disposal unit costs were held constant.
- Flows and loads were assumed to be at full design capacity.
- Additional staff were assumed to be added at current labor costs.
- The "Supplies and Stock", "Parts and Equipment" and "Projects-SRM" line items were reduced based on the future use of reserve accounts to fund repair and replacement (i.e., spare parts) and special projects.
- The "Service Contracts" line was also reduced slightly based on MassDevelopment in-house engineering capabilities and Contract Operations in-house engineering capabilities.

2.6.3. Areas of Uncertainty Related to Costs

Due to the time and scope constraints of this project, there are several areas that could not be explored in greater detail. These items represent areas of uncertainty related to the capital cost estimates. Specific areas of uncertainty consist of the following items:

- WWTF Operational factors – Limited operational data were provided; underlying factors may not have been discovered as a part of this preliminary evaluation.
- Effluent forcemain – Limited information was provided on the reasons for effluent forcemain capacity limitations. More extensive upgrades than those included herein may be required in order to obtain sufficient capacity.
- Rapid Infiltration Basin capacity – Additional capacity may not be approved by DEP.

These areas of uncertainty should be refined as soon as possible.

2.6.4. Additional Costs for Potential Customers

In addition to the costs related to obtaining service from the JBCC wastewater system, potential customers will also need to collect and transport wastewater (or in some cases treated wastewaters) to the JBCC system. This additional infrastructure is costly and may influence the likelihood of the connection materializing. The potential connection costs were estimated as a part of the 2012 CH2M-Hill effort and are summarized in **Table 2-10**. Beyond the connection cost, there may also be costs associated with wastewater collection and/or treatment in the

community served. For example, Bourne would need to construct a landfill leachate treatment facility and effluent forcemain to the JBCC forcemain. Falmouth already has collection, treatment and disposal facilities, so it would have no costs in addition to transport. Mashpee and Sandwich would need sewer systems in order to collect the wastewater volumes. We have estimated these costs "qualitatively" in terms of whether the additional costs are "none", "millions of dollars" or "tens of millions of dollars" to provide some perspective. These qualitative estimates are also summarized in **Table 2-10**. Each community would need to estimate its total costs to connect to JBCC and compare that option to other local options.

TABLE 2-10
ESTIMATED ADDITIONAL COSTS FOR POTENTIAL CUSTOMER COMMUNITIES

Community	Annual Average Flow (gpd) (1)	Cost for Transport to JBCC (1,2)	Cost for Collection (3)	Cost for Treatment (3)	Total Cost (3,4)
Bourne (effluent)	40,000	$	$	$$	$$
Falmouth (effluent)	200,000	$9.6M	n/a	n/a	$$
Mashpee (sewage)	158,000	$4.9M	$$$	n/a	$$$
Sandwich (sewage)	156,000	$8.0M	$$$	n/a	$$$

Notes:
1. Flows are from Section 4.3.2 (Option B) for Bourne and from Section 4.3.4 (Option D) for Falmouth, Mashpee and Sandwich. (CH2M-Hill, 2012)
2. Costs from 2012 CH2M-Hill, Table 4-3 (2012 dollars, say ENR CCI 9400)
3. $ - hundreds of thousands of dollars; $$ - millions of dollars; $$$ - tens of millions of dollars.
4. Total costs include cost for collection, treatment and transport to JBCC, as applicable.

2.7 REGULATORY CONSIDERATIONS

There are numerous potential regulatory issues that MassDevelopment may face in the take-over and upgrading of JBCC wastewater and water facilities. In general, the regulatory issues at JBCC are determined by the location on the base where activities will take place. As noted previously, in broad terms, JBCC has two major components: the Upper Cape Water Supply Reserve; and the Cantonment area. These two areas are shown on **Figure ES-1**.

The Upper Cape Water Supply Reserve consists of approximately 15,000 acres on the north side of the base. It was formally established by the Massachusetts Legislature through Chapter 42 of the Acts of 2002, enacted in March of 2002. The purpose of the Reserve is to protect water

supplies and preserve wildlife habitat. Activities in the Reserve are governed by a detailed set of performance standards that were established in a Memorandum of Agreement between the Commonwealth and the Army and National Guard in 2001. Some revisions in those performance standards were made in 2007. Activities within the Reserve are administered by the DEP Environmental Management Commission.

The Cantonment area includes about 5,000 acres of land on the south side of the base where most of the military activities take place. Activities within the Cantonment are administered by the military. The existing water and wastewater infrastructure is largely located within the Cantonment area, with the following notable exceptions: the wastewater effluent disposal system; the pipeline leading to the wastewater effluent disposal system; and the water pipeline between the three wells owned by the UCRWSC and the Cantonment area.

Beyond normal operations and maintenance activities, modifications to these facilities in the Reserve will require substantial coordination and environmental study in light of the water supply and wildlife habitat protection measures that have been put in place. Additional regulatory requirements from specific regulatory agencies are summarized below.

2.7.1.1 Federal Programs

Based on discussions with MassDevelopment, we are not aware of any federal program requirements for the activities identified in Alternatives 1 and 2. It is conceivable that Alternatives 3 or 4 could trigger a federal Environmental Impact Statement.

2.7.1.2 State – Article 97

The Reserve is considered "Article 97 land", conservation land established under Article 97 of the state constitution. Any attempt to put that land to use for other than conversation purposes requires a two-thirds vote of the state legislature, a very high hurdle. This would make expansion of the RIBs beyond the existing fenceline difficult.

2.7.1.3 State – Massachusetts Environmental Policy Act

The Massachusetts Environmental Policy Act (MEPA) requires that the project proponents study the environmental consequences of their actions, including permitting and financial assistance. It

also requires the proponent to take all feasible measures to avoid, minimize, and mitigate damage to the environment. MEPA review provides the mechanism through which this information collection and mitigation mandate is executed, and it empowers the Secretary of the Executive Office Energy & Environmental Affairs (EOEEA) to oversee the review process. The process is public and encourages comments from citizens and from state, regional and local agencies. MEPA review will be required if MEPA thresholds are exceeded. There have been MEPA reviews of recent military projects, both within and outside the Reserve. The Section 61 findings associated with the 2001 Environmental Impact Report establish more stringent MEPA thresholds for activities within the Reserve. Among other things, MEPA review is triggered by any new wastewater infrastructure there.

2.7.1.4 State – Massachusetts DEP

DEP would need to review and approve the transfer of the Groundwater Discharge Permit from the Air Force/Air National Guard to MassDevelopment. It is expected that the current GWDP would be transferred to Mass Development with few or no substantive changes, following the 30-day notice to DEP of the pending transfer of ownership. A few additional regulatory items are worth noting:

- Sewer Use Ordinance and Industrial Pretreatment Programs would be required by the permit based on MassDevelopment ownership. This would need to in place before ownership transfer.
- A Contract Operator would be required. The selected contract operator must execute an operational contract before the discharge permit can be transferred.
- Potential permit modifications would need to be reviewed and approved by DEP.
- MassDevelopment should request that the phosphorus monitoring requirement be eliminated.
- MassDevelopment should conduct investigation and request a re-rating of the RIB disposal system.
- With an Industrial Pretreatment Program in place, new development on the base could be connected to the wastewater system without the need for a sewer extension permit.

- Similarly, receipt of municipal wastewater from nearby towns would not require a sewer extension permit, assuming no new treatment or disposal capacity is needed;
- If septage receiving facilities were constructed at the treatment plant, DEP approval would be sought via a BRP WP 68 submittal and a request for GWD permit modification;
- Receipt of non-JBCC effluent at the existing rapid infiltration site would require a GWD permit modification, following detailed discussions among Mass Development, DEP and the entity seeking disposal capacity (for, say, effluent from the Falmouth wastewater treatment facility, or effluent from a leachate treatment system at the Bourne landfill).

2.7.1.5 State – Natural Heritage and Endangered Species Program

This program will apply to activities that disrupt wildlife habitat. This will not likely have much impact on Alternative 1 or 2 projects.

2.7.1.6 State – Historic/Archaeological

The requirements of the Massachusetts Historical Commission will apply to new construction, especially related to archeological resources. This will not likely have much impact on Alternative 1 or 2 projects.

2.7.1.7 County – Development of Regional Impact (DRI)

The Commission's DRI process does not apply to state agencies, so DRI review would not occur for Mass Development-initiated projects that exceed DRI thresholds. However, it appears that DRI approval could be needed for large-scale development on Mass Development-controlled land if that land were transferred to a private company.

2.7.1.8 County – 208 Plan

The Cape Cod Commission's Draft 208 Water Quality Plan requests that development at the base be "nitrogen neutral"; that is, new development should not add to the current nitrogen load in nitrogen-sensitive watersheds in a way that increases the cost burden of the towns in the watersheds that have TMDLs. The Cape Cod Commission's Draft 208 Plan also requests that un-used wastewater capacity be provided to satisfy exiting municipal needs and not be used to

promote economic development. MassDevelopment should consider the implications of these requirements and whether it can be compelled to meet the Commission goals.

2.7.1.9 Local Programs

It is unlikely that the Towns of Bourne, Falmouth, Mashpee and Sandwich have any jurisdiction, in a formal permitting sense, for activities to be conducted by Mass Development on the base.

2.8 ALLOCATION OF CAPACITY

The existing JBCC treatment and disposal capacity represents a significant asset on the Upper Cape. As a part of allocation this capacity, MassDevelopment should consider the following important factors:

1. On-Base Sewerage Needs: The existing infrastructure should serve JBCC military and non-military needs/missions.
2. Off-Base Sewerage Needs: Several Upper Cape municipalities have wastewater management needs based on the requirements of the Massachusetts Estuaries Project technical reports. We suggest that MassDevelopment prioritize the capacity allocated to the towns based on the following reasons for "off-site wastewater management", listed in suggested order of "most important" to "least important":
    a. Ensuring sanitary conditions
    b. Protecting public and private water supplies
    c. Protecting surface waters
    d. Allowing for targeted growth (e.g., industrial parks, etc.)
    e. Allowing for general growth
    f. Addressing convenience or aesthetics concerns

3. Trucked Wastes: The existing treatment and disposal capacity is very valuable because the disposal area is not located in a nitrogen-sensitive watershed. Trucked wastes should be used to generate supplemental revenue until such time as sewerage needs infill the remaining capacity. To the extent that a sewerage needs exists, trucked wastes should be encouraged to go "off-Cape" in the mid-term to longer-term.

4. Effluent Disposal: Due to the existing issues associated with I/I, effluent disposal users should be contractually required to "temporarily shut down" upon demand based on weather conditions and peak flows. The user(s) must be able to store or dispose of their flow elsewhere (i.e., to their existing disposal locations or to an alternative trucked waste location) for short-term durations with limited notice.

3 BUSINESS CASE ANALYSIS FOR WASTEWATER ALTERNATIVES

The primary purpose of this evaluation is to conduct a "business case analysis" of various scenarios to determine the risks, costs and revenues associated with MassDevelopment taking ownership of the JBCC wastewater system. The analysis was intended to answer the question *does it make business sense to acquire the JBCC wastewater system and to sell existing capacity to maintain sustainable user rates*? The analysis presented in this section does not include the JBCC water system.

3.1 STEADY STATE BALANCE SHEET ANALYSIS

In order to determine which of the various scenarios presented in Section 2 are most advantageous, Wright-Pierce developed a steady state "balance sheet analysis" for each scenario. On the cost side, the following items were included: current annual O&M costs, debt service associated with potential capital upgrades, new annual O&M associated with MassDevelopment take-over (administration and reserves), new annual O&M associated with the sale of reserve capacity. On the revenue side, the following items were included: existing revenues as well as new revenues from the sale of reserve capacity for sewage, septage and effluent disposal. This analysis is presented in current dollars and does not account for inflation. This analysis also assumes that there is no cost for the transfer of the capital assets from the USAF/ANG to MassDevelopment. The balance sheet analysis is presented in **Table 3-1**.

For this analysis, the rates were set as follows:

- Military: $10/kgal
- Non-Military: $11 to $11.50/kgal
- Septage: $110/kgal
- Effluent: $7.50/kgal

TABLE 3-1
STEADY-STATE FINANCIAL ANALYSIS

	Now	Scenario 0	Scenario 1A	Scenario 1B	Scenario 1C	Scenario 1D	Scenario 2A	Scenario 2B	Scenario 2C	Scenario 2D
Sale of reserve capacity

Net Balance (Revenues minus Costs)	0	0	19	(0)	119	99	46	(75)	145	25
Amount to Subsidize Military Rate or to Supplement Reserves										

Based on this steady state analysis, we conclude that:

- Taking over the JBCC wastewater system will be a financial burden to MassDevelopment ("base case" or Scenario 0) unless capital investments are made and the user base is expanded (i.e., "selling reserve capacity" or Scenarios 1A/B/C/D and 2A/B/C/D). The added O&M costs associated with MassDevelopment take-over, as described above, would create a deficit of $200,000 per year or would require a 40% rate increase to existing customers in order to break even (i.e. from $10.00/kgal to $13.80/kgal).
- The capital investments identified herein allow for MassDevelopment to sell reserve capacity in order to generate revenues from up to four distinct sources: existing sewer users; new sewer users; septage sources; and effluent disposal sources. Scenarios 1A/B/C/D and 2A/B/C/D, which accept various combinations of flow and revenues from each source, are described in detail in **Section 2**.
- Existing sewer user rates charged by JBCC to the existing users do not appear to fully account for the labor associated with operations and maintenance of the wastewater system. Federal organizations at JBCC are not charged for labor because it is already included in the federal budget. Non-federal organizations are charged based on approximately 1 full-time equivalent worker. Moving forward, MassDevelopment should adjust user rates to appropriately account for labor costs since these are "real" costs currently being incurred by the government for provision of wastewater services. When the cost of WWTF operations labor is accounted for, the existing user rate is approximately $11.39/kgal).
- When the cost of WWTF operations labor is accounted for, the existing user rates (approximately $11/kgal) are higher than the "market rate" charged by nearby Cape Cod towns (approximately $5/kgal in Barnstable to approximately $8 to $9/kgal in Falmouth and Chatham). This is due, in part, to higher electrical utility costs as well as the fact that some of the costs for these municipal facilities were covered through grants or through contributions from general municipal taxation.
- The market rate for septage disposal on Cape Cod is between $100 and $110/kgal. We are not aware of any other local circumstances with "effluent disposal users", therefore,

we are not aware of a market rate for effluent disposal. We have established a preliminary effluent disposal rate of $7.50/kgal herein based on an assessment of the value of the effluent disposal capacity to others.

- Based on our steady-state financial analysis as summarized in **Table 3-1** most of the alternatives are expected to generate positive revenue based on the 10-year average of the baseline additional O&M costs associated with MassDevelopment ownership. It is important to note that all rates and costs are presented in current dollars (October 2014, ENR Construction Cost Index 9870).
- In Alternatives 1A through 1D, MassDevelopment take-over plus capital projects would add $620,000 to $660,000 per year in new debt service and O&M costs; however, sale of that reserve capacity would generate $640,000 to $760,000 in annual revenue (i.e., 3% to 15% greater than costs).
- Similarly, in Alternatives 2A through 2D, MassDevelopment take-over plus capital projects would add $1,050,000 to $1,160,000 per year in new debt service and O&M costs; however, sale of that reserve capacity would generate $1,100,000 to $1,180,000 in annual revenue (i.e., 2% to 4% greater than costs).
- Septage (Alternative 1D and 2D) and effluent disposal (Alternative 1C, 1D, 2C and 2D) represent the best opportunities to raise revenue from the sale of reserve capacity. Capacity dedicated to septage in the early years could be converted to additional sewage capacity if/when the neighboring municipalities construct wastewater collection systems under prior agreement with JBCC to receive flow from such facilities. Surplus revenues generated from the sale of reserve capacity should be used to create and fund reserve accounts necessary for asset management, I/I reduction and rate stabilization.
- The net revenue potential for Alternatives 1C/2C is higher than that for Alternatives 1D/2D. This is primarily due to the fact that there are additional capital costs associated with the septage receiving elements of Alternatives 1D/2D. That said, Alternatives 1D/2D provide service to more “categories of users” which MassDevelopment indicates is important. Alternatives 1D/2D represent a more reliable near-term revenue source that could be converted to Alternatives 1C/2C over time if desired. For this reason, Alternatives 1D/2D are carried forward as the recommended alternatives for this

evaluation. It makes financial sense to use or construct capacity that can be utilized for septage in the near term and then converted to wastewater use in the future.

- MassDevelopment should expect to provide significant subsidy to the operation in the early years, until such time as the revenues fully fund the operation by way of new users and "value pricing" of the service. Significant factors related to the subsidy in the early years are the need to establish appropriate reserve accounts, the need to carry fixed costs until new sewage users connect to the system and the need to fund professional services for technical, financial and legal input up to and during the transfer.
- It is important to note that the financial analysis is very sensitive to the rates charged and to whether rates are fixed with or without inflation. Committing to fixed user rates for the military for an extended period of time may require additional subsidy.
- If MassDevelopment can support the capital investments described herein, then then we recommend moving forward with take-over of the wastewater facilities.

3.2 DESCRIPTION OF BUSINESS CASE ANALYSIS

In order to generate the business case analysis, Water Resources Associates was retained to develop a time-variable analysis of costs and revenues for Scenario 1D and 2D. The time-variable business case analysis is described below.

3.2.1. Existing Rate System

The USAF and ANG are not able to fund reserve accounts due to the nature of the accounting system utilized by the federal government. Accordingly, emergency repairs, projects and spare parts must be funded in the "current year" budget. As shown in **Table 2-7**, there is substantial year-to-year variability in the budget. It is also important to note that ANG only charges military users for the "out-of-pocket" costs to run the utility and the labor to operate the facility is treated as a "sunk cost" that is not recouped from the other military sewer users. The ANG does charge a different (and higher) sewer user rate to the Barnstable County Sheriff's Office/Correctional Facility which includes a portion of the labor cost associated with operating the JBCC wastewater system.

3.2.2. Model Inputs and Assumptions

Numerous assumptions are needed to develop a model of this nature. Key assumptions are identified below.

- The assumed timing of the transfer and upgrade activities is:
  - 2015 – activities to transfer ownership of the wastewater system from USAF/ANG to MassDevelopment
  - 2016 – preparation of design plans and specifications for facility upgrades, start receiving sewage from MassDevelopment sources which are already connected to the sewer system
  - 2017 to 2018 – construction and start-up of WWTF upgrade, start receiving limited septage, start receiving effluent disposal
  - 2019 – start loan repayment, start connecting new sewer users
- User Rate assumptions:
  - The user rate paid by military entities will be $10.00/kgal. It is assumed that MassDevelopment's contract with the military will include an annual escalation clause to cover inflation. [Note that some of the scenarios described herein do not inflation of costs, rates or revenues.]
  - It is assumed that the Non-Military user rate will be fixed at $11.00 per 1000 gallons, with the same escalation clause in contracts as discussed above.
  - It is assumed that MassDevelopment and new users of the system (e.g. neighboring towns) would pay actual, annually escalated costs for system services used (e.g. treatment and disposal, treated effluent disposal only)
- Transfer price: to be determined, currently assumed to be "no cost"
- Reserve and operating account requirements:
  - Operating reserve – Two months operating cost, establish over 5 years
  - Debt service reserve – 115% of annual debt service, establish over 5 years
  - Working capital reserve – "single contingency failure" method
  - Pump Station/Collection System asset management reserves - $50,000 per year.
  - I/I Investigation reserves - $25,000

- Sewer Use Ordinance & Industrial Pretreatment Program management - $25,000 per year.

- Interest and inflation rates:
  - Inflation rate (CPI Boston) – 2.0%
  - Interest rate (on reserve accounts) – 0.5%
  - Interest rate on CWSRF Loan – 2.0% (20 year term)
- Costs associated with wastewater system transfer to MassDevelopment:
  - Legal – $30,000
  - Engineering – $400,000 (Includes Project Evaluation Form application, facilities planning, permitting and permit negotiation, program management and contract operations procurement)
  - MassDevelopment Administration – $50,000
  - Financial consulting - $5,000
  - Sewer Use Ordinance and Industrial Pre-treatment Program - Assumed developed by new contract operator of system
  - Engineering design - $472,000 (assuming Design-Bid-Build with contract operations, not Design-Build-Operate procurement)
  - Construction and construction management costs associated with the Baseline Alternative – estimated and financed as documented above.
- Costs associated with <u>future transfer</u> from MassDevelopment to other:
  - None, assumed to be covered out of operating reserves

3.2.3. Net Present Value

A present value analysis is a standard economic evaluation method that allows the calculation of a single "cost" to represent the combination of capital costs and annual expenses for operation and maintenance over an established period of time. In this analysis, the "net present value" (NPV) represents the current value or worth of the net revenue from potential MassDevelopment investments, considering all components of cost and revenues including purchase costs, initial capital costs for upgrade or expansion, capital repair and replacement costs (asset management), annual operating expenses, subsidies fulfill rate guarantees to users, revenues from sale of

capacity and services to system users and other costs and revenues over the 20-year planning period. For the purposes of this study, the NPV has been computed assuming a 2% discount rate for various planning periods (5-year, 10-year and 20-year). The higher the NPV, the greater the potential for generating net revenue from the given investment.

The following parameters were calculated using the business case model in order to provide MassDevelopment with a range of metrics that will be important in considering the financial implications of the decision to acquire the JBCC system:

- NPV to MassDevelopment: 1st five years
- NPV to MassDevelopment: 1st ten years
- NPV to MassDevelopment: 20 year planning period
- Amount of Subsidy by MassDevelopment to the Military Users: 1st five years
- Amount of Subsidy by MassDevelopment to the Military Users: 20 year average
- Amount of Subsidy by MassDevelopment to the Non-Military Users: 1st five years
- Amount of Subsidy by MassDevelopment to the Non-Military Users: 20 year average

A graphical depiction of the time-variable annual costs, annual revenues, reserve account values, WWTF flow rates and user rates are presented in **Figure 3-1** and **Figure 3-2**, respectively. **Table 3-2** presents a summary of these key financial metrics for Scenario 1D and 2D.

It is clear from the model output and this summary table, that the revenue from septage and treated effluent disposal, commencing in year 2018 under the current assumptions, are the factors that drive the intermediate and long-term financial benefit of the project. The NPV of the project would be negative $197,500 through the first 5 years of the project (that is, the costs of the investments will exceed the associated revenue); however, the NPV for the 10-year and 20-year horizons are positive $632,000 and $1,997,000, respectively (that is, the investment turns profitable in the later years to more than offset the "unprofitable" early years). Scenario 2D has a similar trend in the financial metrics, except that it is "more negative" in the first 5 years and "less positive" at the 10-year and 20-year horizons.

FIGURE 3-1: TIME-VARIABLE FINANCIAL ANALYSIS
ALTERNATIVE 1D (BASELINE)

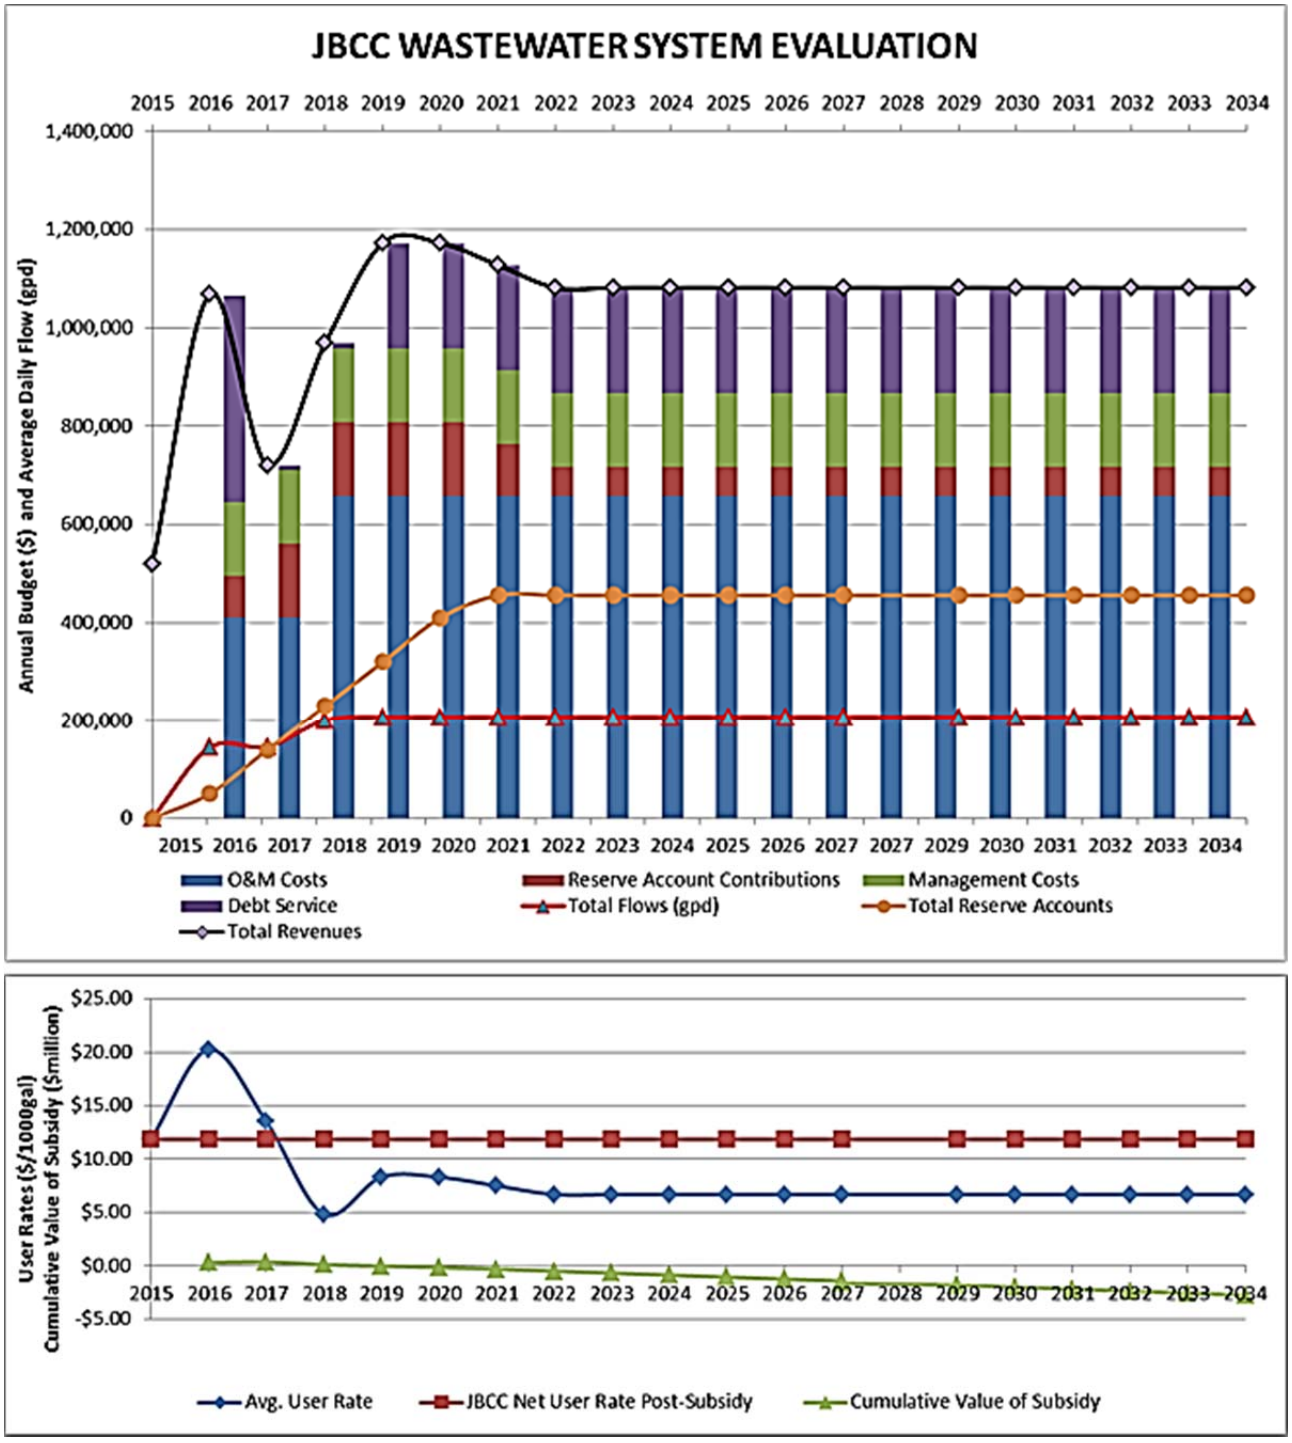

FIGURE 3-2: TIME-VARIABLE FINANCIAL ANALYSIS ALTERNATIVE 2D (EXPANSION)

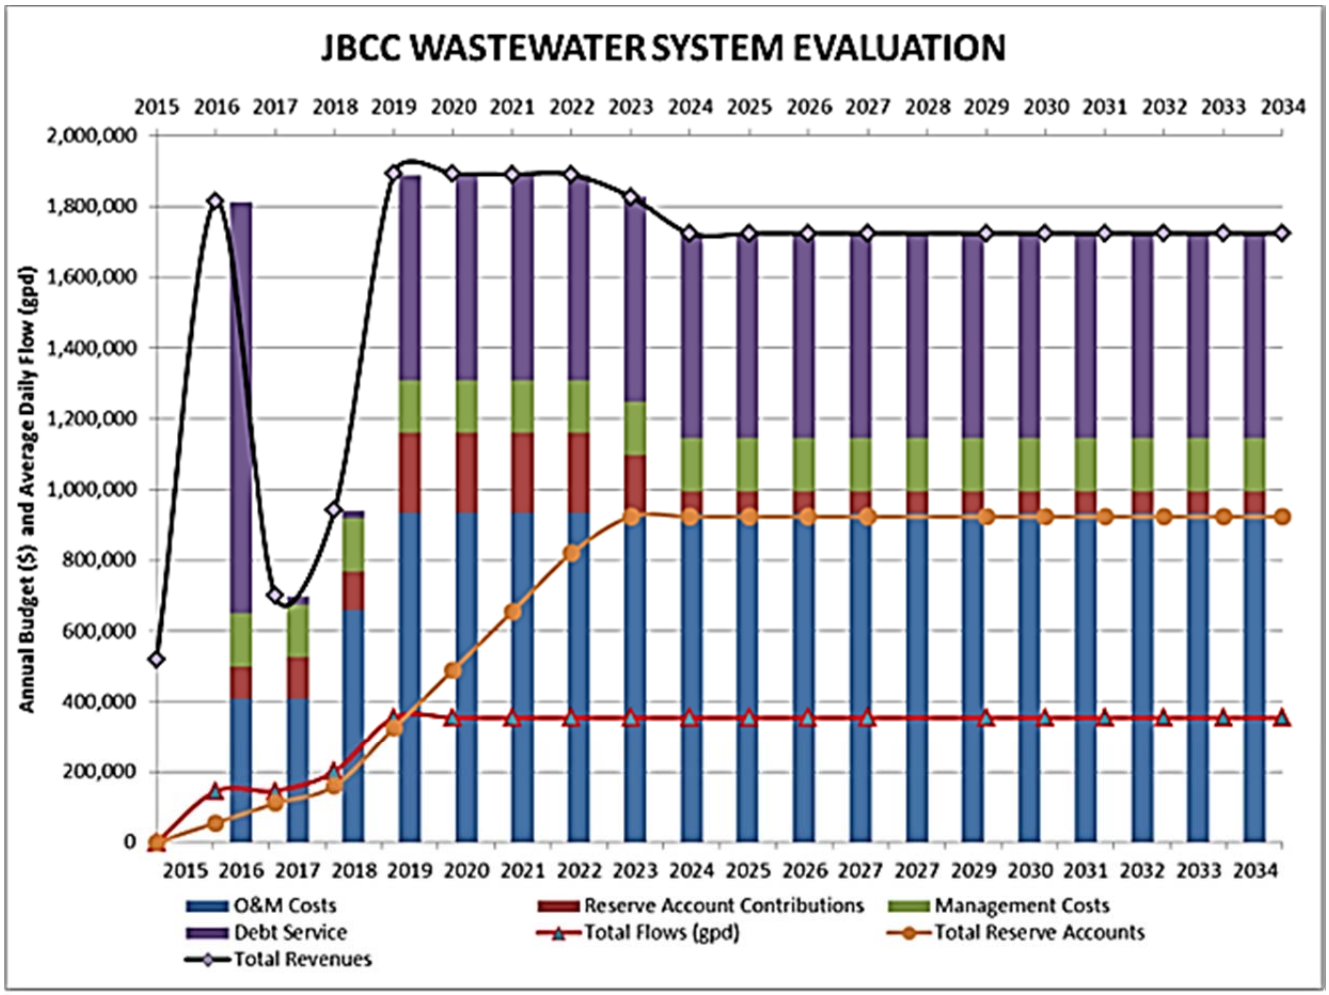

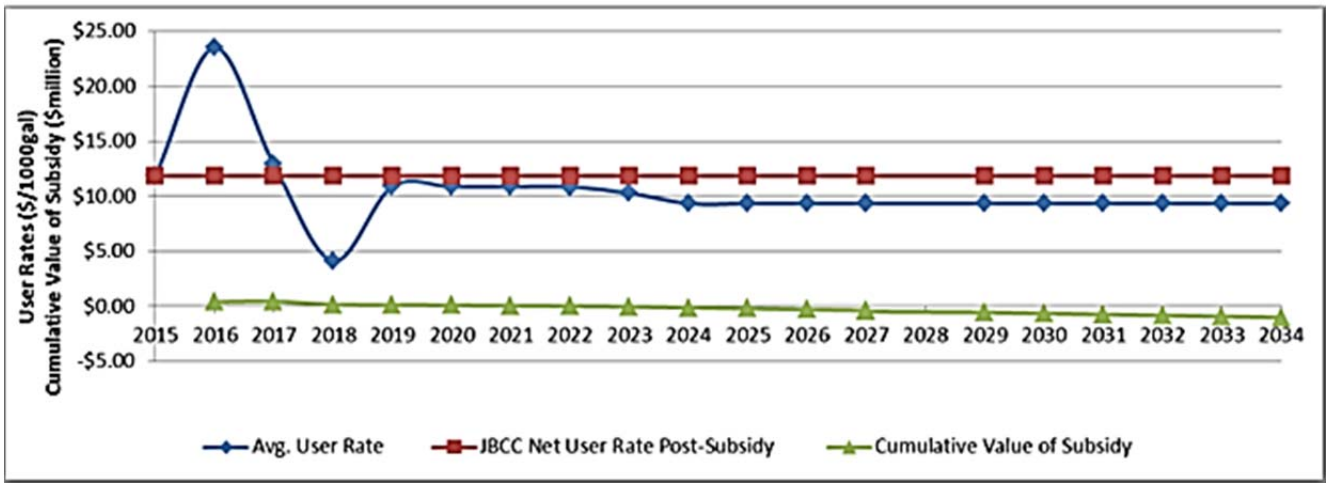

TABLE 3-2
FINANCIAL METRICS FROM TIME-VARIABLE BUSINESS CASE MODEL

Scenario Metrics	Scenario	1D	2D
	JBCC Wastewater	X	X
	Septage	X	X
	Landfill Leachate	X	X
	Regional Wastewater		X
MassDevelopment-Military Subsidy, 1st 5 years (Cumulative)		$ 171,500	$ 422,800
MassDevelopment-Military Subsidy, 20-yr Annual Average		$ (74,800)	$ 12,000
MassDevelopment-Non-Military Subsidy, 1st 5 years (Cumulative)		$ 8,700	$ 130,800
MassDevelopment- Non-Military Subsidy, 20-yr Annual Average		$ (50,600)	$ (9,100)
Net Present Value, 1st 5 Years - MassDevelopment (Cumulative)		$ (197,500)	$ (547,700)
Net Present Value, 1st 10 Years - MassDevelopment (Cumulative)		$ 632,000	$ (259,900)
Net Present Value, 20 year - MassDevelopment (Cumulative)		$ 1,997,200	$ 630,200
MilitaryProjected Rate/1st 10 years ($/kgal)		$ 10.00	$ 10.00
Military Current Projected Rate/No Subsidy/10 Years ($/kgal)		$ 11.85	$ 11.85
MilitaryProjected Rate/1st 10 years/Excess Revenue to Military Rate ($/kgal)		$ 8.66	$ 10.00
Non-Military Projected Rate/1st 10 years ($/kgal)		$ 11.00	$ 11.00

3.2.4. Sensitivity Analysis

The time-variable model was used to conduct a number of sensitivity analyses for Scenario 1D in order to compare the "baseline case" (i.e., no inflation) to several other conditions. These analyses are described below. The results of the sensitivity analyses are presented in **Table 3-3**.

3.2.4.1 Analysis of Fixed Military User Rate – Current Full Rate

The assumed military user rate of $10.00/kgal has been used. As described previously, the current user rates do not appear to include the full labor cost associated with running the facility and the estimated user rate including labor is $11.39/kgal (in 2013 dollars). If this rate is escalated by 2% per year, the current rate would be $11.85/thousand gallon (in 2015 dollars). If this rate is used as the starting military rate, along with a similar increase in the non-military rate, the NPV improves significantly. This additional revenue can be used to fund system improvement such as I/I reduction and asset management.

TABLE 3-3
SENSITIVITY ANALYSIS FROM TIME-VARIABLE BUSINESS CASE MODEL

Scenario Modification	NPV 5 years	NPV 10 years	Military Rate 10 yr avg	Non-Military Rate 10 yr avg
Baseline: No inflation, Initial User Rates	$ (197,500)	$ 632,000	$ 10.00	$ 11.00
Military Rate at **Current Full Rate** ($11.85/kgal)	$ 256,800	$ 1,510,000	$ 11.85	$ 12.85
Military Rate - **Breakeven Subsidy**	$ 35,200	$ 1,081,000	$ 10.95	$ 11.95
Baseline: No inflation, Initial User Rates	$ (197,500)	$ 632,000	$ 10.00	$ 11.00
Baseline: Initial User Rates **2% annual inflation on all costs and revenues**	$ (87,500)	$ 1,019,000	$ 11.17	$ 12.29
Baseline: Initial User Rates **3% annual inflation on all costs and revenues**	$ (30,300)	$ 1,229,000	$ 11.81	$ 12.99
Baseline: No inflation, Initial User Rates **Septage Tipping Fee** = $110/kgal	$ (197,500)	$ 632,000	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates **Septage Tipping Fee** = $130/kgal	$ 106,000	$ 1,403,000	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates **Septage Tipping Fee** = $100/kgal	$ (349,300)	$ 246,500	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates **Effluent Disposal Fee** = $7.50/kgal	$ (197,500)	$ 632,000	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates **Effluent Disposal Fee** = $10.00/kgal	$ (96,353)	$ 889,053	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates **Effluent Disposal Fee** = $6.00/kgal	$ (258,200)	$ 477,900	$ 10.00	$ 11.00
Baseline: No inflation, Initial User Rates	$ (197,500)	$ 632,000	$ 10.00	$ 11.00
Baseline: Optimized Best Case Military Rate: Current Full Rate = $11.85/kgal Septage Rate = $120/kgal Effluent Disposal Fee = $8.50/kgal	$ 598,700	$ 2,540,000	$ 11.85	$ 12.85

3.2.4.2 Analysis of Fixed User Rate – Breakeven Subsidy

The baseline case assumes that the military and non-military rates are set at $10.00/kgal and $11.00/kgal, respectively, are "held constant" over the planning period. Positive net revenue will be retained by MassDevelopment and can be used to fund system improvements such as I/I reduction and asset management. The baseline case shows that Scenario 1D will have net

positive revenue approximately 7 years after MassDevelopment takes over. The implications of this point are that, in transfer negotiations in order to provide a more favorable financial internal balance sheet over the first 5 to 7 years, MassDevelopment could guarantee the military users the current rate, escalated as discussed above, but ***as averaged over the 20-year period***. This would provide higher Military rates during the first 10 years with reduced rates in subsequent years, providing the overall goal of constant rates. It would also allow MassDevelopment to "break-even" for the first few years, rendering the transfer more financially attractive to MassDevelopment. The business model was also run to determine the military and non-military rates at which the subsidy by MassDevelopment for the first five years would be zero. As shown on **Table 3-3**, the break-even subsidy rates are $10.95/kgal and $11.95/kgal for the military and non-military customers, respectively, only about 9% higher than the baseline rates.

3.2.4.3 Analysis of the Impact of Inflation

Table 3-3 shows the key financial metrics assuming 2% inflation per year and 3% inflation per year applied to all user fees, revenues and costs, including capital repair and replacement costs (starting with the initial user fees of $10.00/kgal and $11.00/kgal for military and non-military customers, respectively). The tests for inflation show that the NPV improves under both cases. The 10-year average user rate increases to $11.17/kgal and $12.29/kgal for military and non-military users, respectively, under the 2% inflation scenario. The 10-year average user rate increases to $11.81/kgal and $12.99/kgal for military and non-military users, respectively, under the 3% inflation scenario.

3.2.4.4 Analysis of Septage Tipping and Effluent Disposal Fees

Table 3-3 shows the key financial metrics at variable septage tipping fees and effluent disposal fees. An increase in the septage tipping fee from $110/kgal to $130/kgal (an 18% increase) improves the NPV by 122%; whereas a decrease in the septage tipping fee to $100/kgal (a 9% decrease) reduces the NPV by 61%. This analyses shows that the viability of the project is very sensitive to septage tipping fees. Similarly, an increase in the effluent disposal fee from $7.50/kgal to $10.00/kgal (a 33% increase) improves the NPV by 41%; whereas a decrease in the effluent disposal fee to $6.00/kgal (a 20% decrease) reduces the NPV by 21%. This analysis

shows that the NPV and subsidies are not as sensitive to effluent disposal fees as they are to septage disposal tipping fees, and illustrates the need to closely monitor the markets for disposal of these wastes.

3.2.4.5 Optimized Best Case

The results of these analyses show that the baseline case is conservative and that the net present worth improves (or does not worsen) if the user rates and operations costs are increased with inflation. We considered a scenario that is referred to as the "optimized best case": a combination of a modest increase in the initial full user rate to be charged to the military ($11.85/kgal vs $10/kgal) and non-military customers ($12.85/kgal), a small increase in the septage tipping fee ($120/kgal vs $110/kgal) and effluent disposal fee ($8.50/kgal vs $7.50/kgal). In summary, this produces a financially attractive project (NPV of $2.5 million) that would provide significant revenues for system management and risk resolution.

3.2.5. Summary and Recommendations

If MassDevelopment can support the capital investments described herein and if MassDevelopment can secure binding commitments from potential new users (commitment to connect, financially contribute, pay user rates and abide by the sewer use ordinance), then then we recommend implementing **Alternative 1D** (i.e., baseline improvements with upgrades to accept some new sewage as well as septage and effluent disposal). Alternative 1D has a higher net present value, has less risk and fewer regulatory, institutional and financial complexities. This could be expanded to **Alternative 2D** (i.e., 50% capacity expansion with upgrades to accept new sewage, septage and effluent disposal) if Mashpee can secure Town Meeting approval(s) to proceed with its CWMP. Key conclusions from this analysis are:

- Subsidy is required in the first 5 years, declining from the first to the fifth year.
- For Alternative 1D, the net present value is positive between Year 6 and 8.
- For Alternative 2D, the net present value is positive between Year 12 and 14.
- In order to minimize risk to MassDevelopment, it will be important to get formal commitments from potential users (i.e., municipalities) with regard to the capital costs for upgrades as well as to the proposed user rates. Potential customer municipalities will

need to compare the proposed user rates versus their other wastewater management alternatives.

3.2.6. Other Potential Revenue Sources

MassDevelopment may want to consider the following additional mechanisms to raise revenue as a means to further develop reserve accounts and to mitigate risk:

- Connection Fees – Develop connection fees based, in part, on the existing value of the system that was paid for by others.
- Host Fees – MassDevelopment could charge "host fees" to "customer towns". These fees could be a flat fee or a variable fee and would be in addition to the user fees associated with actual flows and loads discharged to the treatment system.
- Infiltration/Inflow Fees – I/I fees could be utilized as a cost-based incentive to have facility/building owners remove I/I sources from their facility/building (e.g., roof leaders, sump pumps, etc.). If the facility/building owner is unwilling or unable to remove the I/I source, then the fee would be charged.
- Industrial Pre-Treatment Program Fees – It is common for sewer users in the Industrial Pre-Treatment Program pay additional fees to cover the additional administrative and monitoring costs associated with this category of user.
- Loading Surcharges – It is common for sewer users that discharge high-strength wastewaters to pay loading surcharges to cover the additional processing costs associated with this type of wastewater.

Each of the above fee types has advantages, disadvantages and challenges (e.g., public acceptance, administrative complexity, etc.). Analysis of these factors is beyond the scope of this study but should be considered in greater detail prior to advancing towards implementation.

4 ASSESSMENT AND MANAGEMENT OF RISKS

There are numerous potential risks associated with the take-over of a wastewater utility such as the JBCC wastewater system; however, it is important to understand that these risks are inherent to sewerage infrastructure and are similar to those faced by many small municipal wastewater systems throughout New England. A summary of these risks is presented in **Table 4-1**. In general, these risks can be satisfactorily addressed through:

- Well-crafted transfer documents;
- Proactive utility management;
- Thorough Sewer Use Ordinances and Industrial Pre-treatment Programs;
- Dedicated reserve accounts;
- Clear delineation of ownership of building - specific pump stations and service laterals;
- On-going and intensive condition assessments in the collection system;
- Well-operated and maintained treatment and disposal facilities; and
- User rates and connection fees established to provide for sustainable revenues to adequately fund operations and reserve accounts.
- Service agreements with new users that set a minimum annual revenue value.

There are several JBCC-specific items which MassDevelopment should consider in its negotiations with USAF/ANG, including:

- Segregating liability related to legacy pollutants;
- Obtaining consent for “right of access to inspect” through the Sewer Use Ordinance and Industrial Pre-Treatment Program;
- Coordinating access and pipe routing issues associated with each potential “revenue source” (e.g., sewer connections to the WWTF, septage haulers to the WWTF, effluent disposal connection to the existing effluent forcemain).
- Coordinating with JBCC commanders to identify opportunities to reduce the extent of the collection system (i.e., abandon piping when consistent with the JBCC mission);

- Coordinating “ownership” of service laterals and small pumping stations with the existing sewer users and documenting in the Sewer Use Ordinance.
- JBCC is not able to fund reserve accounts due to the nature of the budgeting and accounting approach utilized by the federal government. Accordingly, planned maintenance, emergency repairs and special projects must be funded in the “current year budget”. This produces relatively large year-to-year variability in the budget. If MassDevelopment were to take-over the wastewater collection system, MassDevelopment would have to increase O&M costs in order to address administration costs and reserve account funding.

TABLE 4-1
IDENTIFICATION AND MANAGEMENT OF RISKS

Risk	Potential Cost	Likelihood Near-Term (0 to 5 yrs)	Likelihood Long-Term (10 to 20 yrs)	Management Strategy
Legacy pollutants are identified	Unknown	Medium	Medium	• Craft transfer documents to exclude liability for legacy pollutants related to easements and/or real property
Collection system piping failures and/or pump station failures	$$	Medium	High	• Conduct condition survey • Craft transfer documents to leave "service piping" and/or "private pump stations" with the existing owners. • Establish reserve accounts to fund asset management • Reduce extent of system
MassDevelopment expends costs to conduct studies and facilitate transfer but transfer does not happen	$ to $$	Medium	Low	• Execute MOU with interested towns to share in evaluation and implementation costs • Secure OEA funding.
Cost-effective I/I removal not found	$	Low	Medium	• Reduce extent of system, construct influent equalization
Increased RIB capacity not approved by DEP	$	Medium	Low	• Obtain DEP approval prior to committing to new customers
Military Users and/or Effluent Users do not comply with SUO/IPP	$	Low	Low	• Require acceptance certification as a part of transfer documents • Utilize escrow account in lieu of fines
Septage haulers don't use facility	$$	Low	Low	• Lower septage tipping fee to below market rate to increase use
New users don't agree to rates	$$	Medium	Low	• Require commitment prior to advancing acquisition
New users fail to connect	$$	Medium	Low	• Require IMA or MOU prior to constructing upgrades
Fixed user rates are not adequate	$	Medium	Low	• Establish rate stabilization reserves, raise rates if necessary
DEP imposes more stringent GWDP requirements	$$$	Low	Low	• Confirm GWDP requirements prior to expanding WWTF. • Raise revenue to construct upgrades

Notes: $ - tens of thousands of dollars; $$ - hundreds of thousands of dollars; $$$ - millions of dollars

5 WATER SYSTEM

5.1 INTRODUCTION

This section of the report describes the existing water works, water demands, and adequacy of supply. This section of the report also provides an alternatives analysis and costs for potential water system upgrades.

5.2 DESCRIPTION OF EXISTING WATER SYSTEM

A brief description of the waterworks facilities and how the system operates and is maintained is presented below. The facilities, distribution system and other features of the JBCC are shown in **Figure ES-2**.

5.2.1. JBCC Water Supply

The JBCC is supplied public drinking water from two supplies: 1) the J-Well located on the JBCC, and 2) wholesale interconnection with the Upper Cape Regional Water Supply Cooperative. The system also maintains an emergency interconnection with the Mashpee Water District. This interconnection is rarely used. A brief description of the limitations of the two primary sources of supply and operation of the system is presented below.

5.2.1.1 Interconnection with the Upper Cape Regional Water Supply Cooperative

The primary source of supply for the JBCC is the Upper Cape Regional Water Supply Cooperative (UCRWSC). The primary point of interconnection is located in a vault near the JBCC's other source of supply, the J-Well. The Upper Cape Regional Water Supply Cooperative (UCRWSC) was established in 2000 by the Massachusetts Legislature (Chapter 352 of the Acts of 2000). A copy of the enabling legislation is included in Appendix D. The UCRWSC is governed by a Board of Managers with representatives from the Bourne Water District, Town of Falmouth, Sandwich Water District and the Mashpee Water District.

The UCRWSC has three groundwater supplies referred to as Well No. 1, Well No. 2 and Well No. 3. The Water Management Act (WMA) permit and the enabling legislation allocates maximum daily volume reserves to each participating water system as well as a little over 500,000 gallons per day (gpd) reserved for use by the JBCC. Each well is restricted to a maximum daily withdrawal of 1.5 million gallons per day (mgd) and an average daily withdrawal of 1.0 mgd (3.0 mgd total). Each of the remaining participating water systems has a daily maximum allocation of 500,000 gpd, except Falmouth, which has a reserve allocation of 1.0 mgd.

The UCRWSC is the preferred supply for the JBCC because of its higher quality and lower cost. Presently, the JBCC uses far less water than the allocated reserve volume from the UCRWSC because of low demands. The pH of the UCRWSC supply is adjusted with potassium carbonate to match the finished water conditions of the J-Well as described below. The JBCC contract price for water from the UCRWSC is $1.0 per thousand gallons purchased.

5.2.1.2 J-Well Groundwater Supply (PWS ID #4096001)

The J-Well is an active gravel-packed well supply located in the JBCC service area. The well is operated in accordance with a Certificate of Registration issued by the Massachusetts DEP. A copy of the DEP Registration Statement is included in Appendix D. The registration statement allows a maximum annual withdrawal volume of 197.1 million gallons (Mgal) and an average daily withdrawal volume of 540,000 gpd. The single well is equipped with a 150 horsepower vertical turbine well pump powered by a variable frequency drive unit. The pump can produce approximately 1,400 gallons per minute. A new pump motor was installed in the 1990s.

The J-Well site contains four primary structures; the pumping station which houses the well pump and chemical feed equipment, a chemical injection vault, an inactive carbon contactor building constructed in 1998 and a generator building housing a gas-fired auxiliary generator.

The generator, chemical injection vault and carbon contactor building were installed in the 1990's. The pumping station is in relatively good condition for a building of this age. The

chemical systems are compact and situated in very close proximity to electrical and control equipment. Any major renovations of this space would likely trigger building and life safety codes and require repurposing this space. The well pump discharges through a basement level to an exterior chemical injection vault before entering the distribution system through two parallel 10-inch diameter water mains. Both locations are confined space areas.

The J-Well is much more costly to treat and pump to the distribution system than wholesale purchase of bulk water from the UCRWSC. The source is treated with three chemicals: sodium hypochlorite for disinfection; potassium carbonate for corrosion control and pH adjustment; and sodium fluoride for tooth decay prevention.

The natural low pH of the water and the depth to the water table are the two primary factors driving the cost of production at the J-Well. The chemical feed systems were overhauled in the late 1990's. The J-Well is normally only operated one day per week. The production cost for the J-Well is high because of the large pump horsepower of the well and substantial chemical feed requirements. The well is oversized for the demands and water-use patterns at JBCC. The present well capacity is approximately 2.0 mgd. Average-day demands ranged from 176,700 gallons/day to 189,100 gallons/day over the past three years. Operators also report that intermittent operation of the well improves water quality from stagnant water and accumulation of metals in the piping and well casing during downtimes. Operation of the well on an infrequent basis also reduces the risk of the MassDEP declaring the well inactive.

The future viability of the J-Well as a source of supply for the JBCC is discussed later in the assessment. In the 1990s, VOCs were detected in the J-Well. A granular activated carbon (GAC) adsorption system was constructed to remove the contaminant following issuance of an administrative consent order by the DEP. GAC contactors were constructed in a pre-engineered metal building located adjacent to the pumping station. This system is reported to be inactive.

5.2.1.3 Water Quality

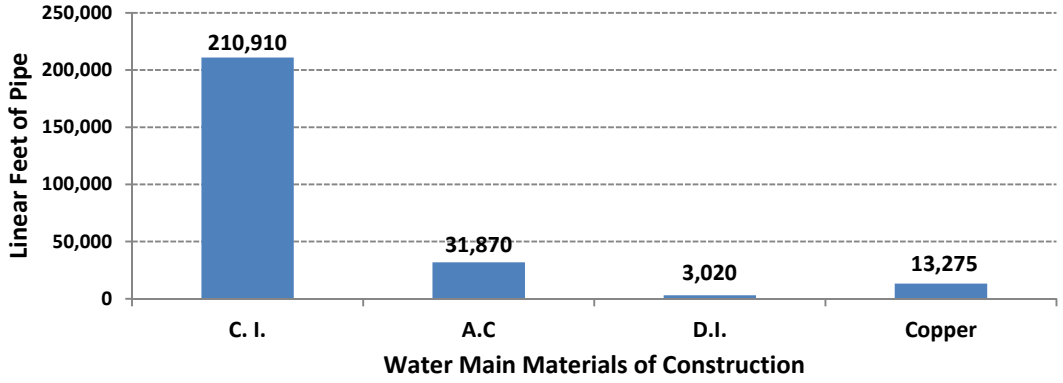
Maintaining high quality, delivered water to the customer's tap has been an issue in the system at certain times. Finished water meets all state and federal maximum contaminant levels (MCLs). Operators report that treated water has an apparent color range of 5 to 10 color units. Staining of bathroom fixtures is common is some facilities. Some service connections have installed cartridge filters to improve water quality and to reduce oxidized iron and manganese in the system. The change in water quality from the sources of supply to the customer's tap is likely a combination of unlined cast iron piping and a polyphosphate feed system that is not optimized to completely sequester the metals from the well supply. The water quality issues appear to be aesthetic in nature and not a concern for public health.

5.2.2. Water Distribution

The original water distribution system was constructed in 1940 to 1941. This original system consisted of about 144,000 lineal feet of unlined cast iron water main ranging in size from 2-inch to 12-inch in diameter. The next major expansion of the water distribution system occurred from 1955 to 1960 consisting of an additional 112,000 lineal feet of new mains, as the core system expanded outwardly to encompass the current Coast Guard Housing and Coast Guard Non-Housing areas. Most of this new main consisted of cement lined cast iron main plus the addition of approximately 32,900 feet of asbestos cement (transite) mains in the main base area. The asbestos cement water mains have been a source of repairs and maintenance issues in recent years. Operators report that much of the asbestos cement pipe is brittle and soft. Repairs to this older pipe are increasingly a problem in the system. The asbestos cement pipe does not have vinyl chloride linings and as such does not require bleeders to maintain water quality. Small amounts of modern copper and ductile iron pipe are present, but the quantities are small and limited. The distribution system has been virtually unchanged since the 1960's with the exception of pipe repairs, and replacement or addition of isolated valves and hydrants.

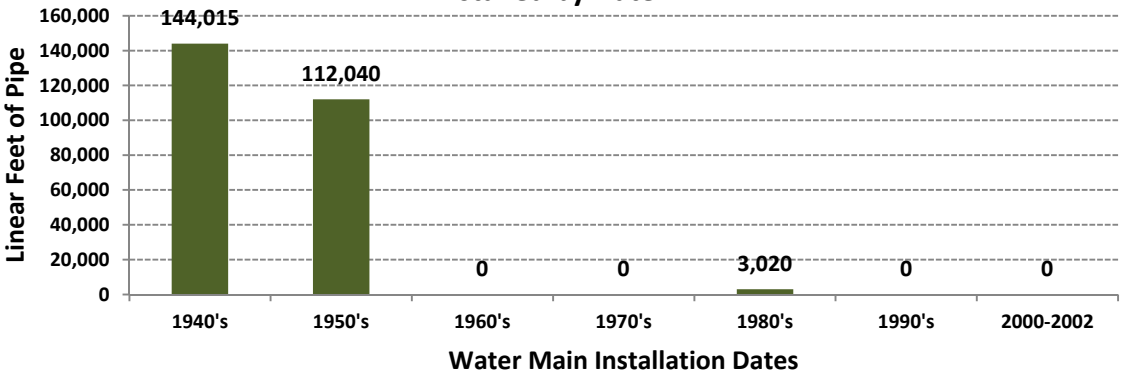
The total length of mains in the JBCC water distribution system is approximately 259,000 feet or 49 miles. The distribution of the water mains by pipe material type is presented in **Figure 5-1**.

Figure 5-1 - JBCC Water Distribution System - Linear Feet of Main by Material Type



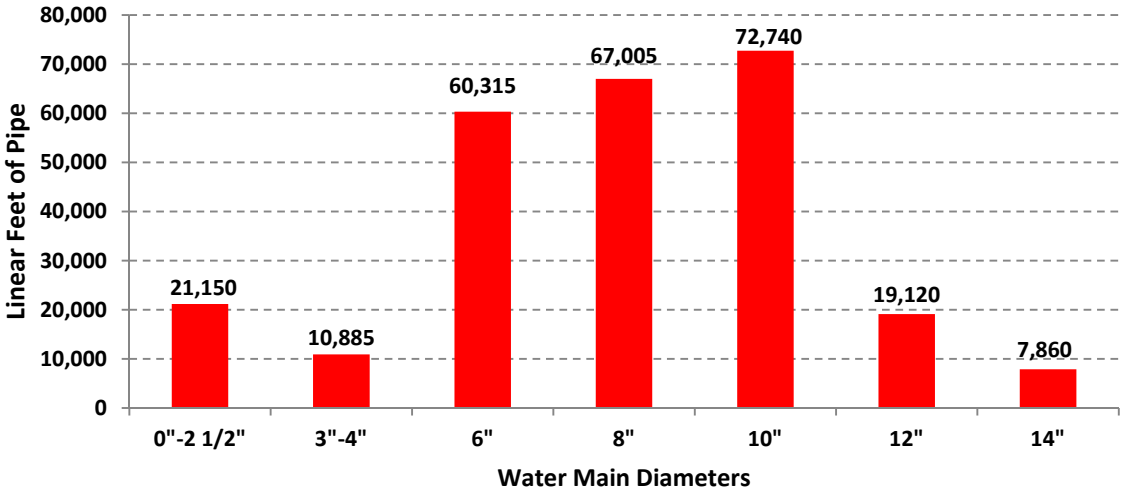
The distribution of the mains in the system by year of installation is presented in **Figure 5-2**. As discussed above, the vast majority of piping was installed prior to 1961.

Figure 5-2 - JBCC Water Distribution System - Linear Feet of Main Installed by Date



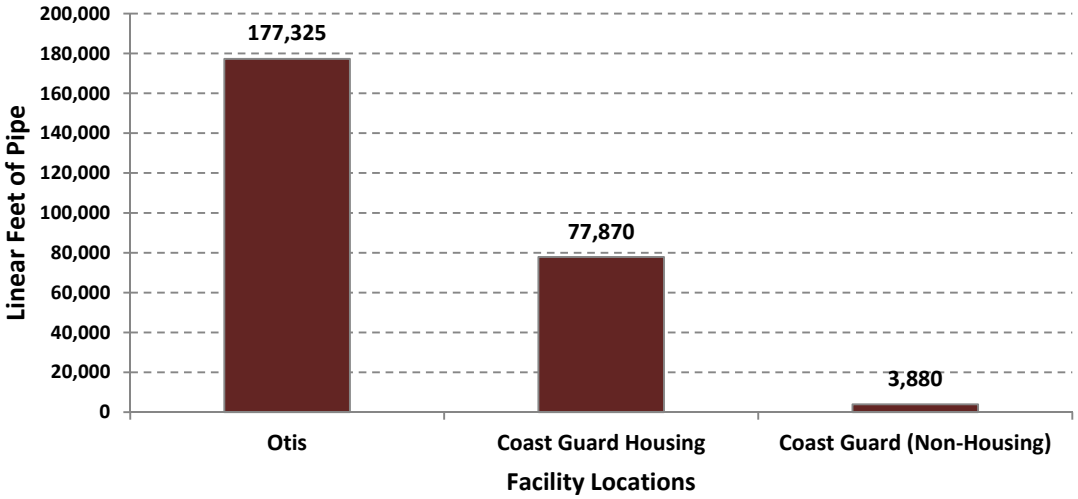
The distribution of the mains in the system by pipe diameter is presented in **Figure 5-3**. The primary core of the distribution system contains 6-inch, 8-inch and 10-inch water mains.

Figure 5-3 - JBCC Water Distribution System - Linear Feet of Main by Pipe Diameter



The distribution of the mains in the system by primary location in the JBCC is presented in **Figure 5-4**. The majority of the piping is located within the main base area.

Figure 5-4 - JBCC Water Distribution System - Linear Feet of Main by Location



A hydraulic model of the distribution system does not exist so simulated available fire flows at each hydrant are not available. However, the prevalence of 6-inch and 8-inch mains suggest that hydrant flows throughout much of the service area will be limited and likely below Insurance Services Organization (ISO) recommendations for the type of large structures found on the JBCC.

5.2.3. Service Connections, Metering and Backflow Prevention

The base maintains an active cross connection control program and has 4 licensed backflow testing technicians on staff. Presently, the system maintains an inventory of devices and has a formal policy of specifying devices and billing the tenants for the installation, maintenance and testing of the devices. Individual structures are not individually metered. Water bills are generated based on a usage algorithm that was not made available.

It is understood that each individual structure will require an individual flow meter, corner horn for mounting the meter, and a backflow prevention device (reduced pressure zone (RPZ) or double check valve) depending on the nature of the service connection. The cost to install a meter assembly should be relatively fixed for each existing service connection. The cost could be funded through a one-time assessment or through water rates.

MassDevelopment has requested a plan to provide water meters at each service connection. Flow meters are sized based on the diurnal water-use pattern at the service connection. A preliminary service count was obtained by counting existing structures with service connections from the GIS mapping. About 380 services to occupied buildings are shown in the database. For the purposes of this evaluation, the costs to extend metering to each service have been evaluated. A fixed cost allocation of $3,000 per service connection has been assumed to provide a meter, meter cornerhorn, radio read or touchpad devise and for an initial surveillance of the properties to determine best location for the equipment. It is recognized that the meter size will vary by location, but for planning purposes a fixed budget cost to account for some variation from service to service is reasonable.

Our cost assumptions to install service meters in the JBCC system are as follows:

- Estimated cost to install 380 service meters $1,140,000 (2014 dollars)
- Number of meters - $380 ranging in size from 5/8" to 2"
- Average Cost per Service Installation- $3,000
- Funding Period – 20 years
- Annual inflation rate – 2%
- Interest rate – 2 %

5.2.4. Water Storage and Fire Protection

Fire storage in the water system is provided by two, 400,000-gallon elevated water storage tanks. One tank is located off Shelton Road (Facility 2302) and the other tank is located off Granville Road (Facility 2303). The tanks were constructed in 1942, dating back to the origin of the water system. Both tanks were refurbished in the early 1990s with new cathodic protection systems, obstruction lighting, new interior and exterior coatings and repair of various structural components. Both tanks will have a new maintenance cycle completed by the end of 2015.

Both tanks are reported to be equipped with 12-inch altitude valves located in buried vaults at each facility. It is not known if the valves are operational or if the control point is set below the overflow elevation to control overflow events at the tanks. The valves and vaults were added to the system as part of the rehabilitation projects in the early 1990's.

The system contains about 270 fire hydrants dispersed through of the distribution system for fire protection. Many of the hydrants date back the original distribution system or were added with the expansion in the 1950's. The condition, operability and presence of adequate branch valves to isolate hydrants are not known at this time.

Operating pressures are reported to range from a low of about 40 psi to high pressure of 70 psi. This data would suggest that the tanks are about 100 feet high. Record drawings were not made available to confirm the operating parameters, height and bowl dimensions of the two storage tanks.

Both tanks are approaching 75 years old and both are constructed using an older, high maintenance technology for water storage. Since the tanks are nearly 75 years old, we have assumed that the structures are fully depreciated with no remaining residual value. An analysis of the adequacy of this storage system to meet projected demands and fire requirements at the JBCC is discussed later in the report.

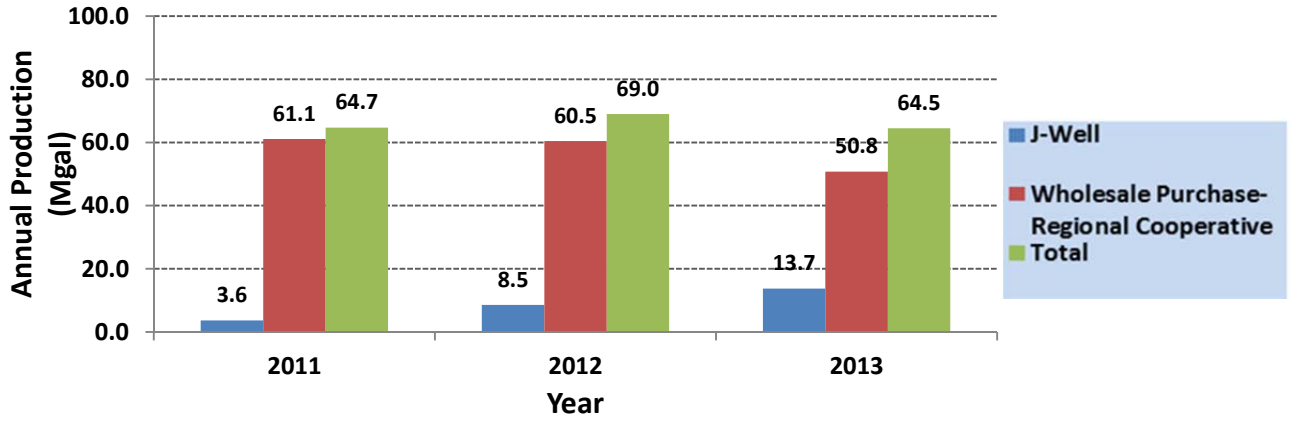
5.2.5. Water System Classification

The JBCC is classified as a Class I public water treatment system. The person with responsibility for making process system integrity decisions about water quality or quantity that affect public health, and having active field supervision of treatment activities must hold the appropriate Grade 1T or higher grade treatment certificate. The JBCC is classified as a Class II public water distribution system. The person with responsibility for making process system integrity decisions about water quality or quantity that affect public health, and having active field supervision of the distribution system activities must hold the appropriate Grade 2D or higher grade treatment certificate.

5.3 EXISTING DEMANDS AND WATER USE

The annual water usage at JBCC over the past three years is presented in **Figure 5-5**. The figure also shows the apportionment of demands between purchased water from the Regional UCRWSC and production from the J-Well. The J-Well has produced between 6% and 21% of the total demands in the system over the past three years.

Figure 5-5 – Water Demands in JBCC for the Period 2011-2013



The data suggests that the use of the J-well has diminished in importance over the last several years because of the much higher production cost. The J-well continues to be used however for a small portion of the production for several reasons; (1) Intermittent use of the well is needed to maintain water quality and prevent high concentration of iron and manganese in the well and (2) To maintain the well in active status with the MassDEP for redundancy to the preferred water from the UCRWSC.

Unaccounted-for water in the JBCC system is understood to be high. Routine leak detection surveys have not been completed and consumption is not metered. However, flow data from the wastewater treatment facility does provide some insights into lost water in the system.

Water production (J-Well plus purchased water from the UCRWSC) has averaged 64.5 Mgal/year or approximately 176,500 gallons/day over the past three years. Average influent at the wastewater treatment facility has averaged approximately 131,000 gallons/day (See Table 2-1) over the same period, including contributions from inflow and infiltration (I/I) in the sewer collection system. These data suggest that unaccounted for water has averaged at least 45,000 gallons/day or 25.5% of water demands plus contributions of I/I.

5.4 ADEQUACY OF STORAGE AND SUPPLY

5.4.1. Supply Evaluation

The adequacy of the JBCC supply was evaluated for the following conditions:

- Adequacy of Supply to meet projected average-day demand conditions
- Ability of supply to meet maximum-day conditions
- Ability of supply to comply with Massachusetts Water Management Act

For the purposes of this evaluation, the capacity constraints of the wastewater treatment facility are important. Although it is likely that sufficient development will not occur within the JBCC service area to absorb any capacity through growth, our analysis will consider this condition only from the supply adequacy perspective.

5.4.1.1 Average-Day Demands

The present average-day demands in the JBCC system have been 176,500 gallons/day or 64.5 Mgal/year over the past three years. The J-Well and UCRWSC agreement are both constrained on annual yield or contract limits to supply the needs of the JBCC.

The UCRWSC agreement allows for a maximum-day purchase of 500,000 gallons on any given day during the year. On an annual basis, this equates to approximately 183 Mgal/year. For the J-Well, the Water Management Act registration statement limits the annual withdrawal volume from the well to 197.1 Mgal/year.

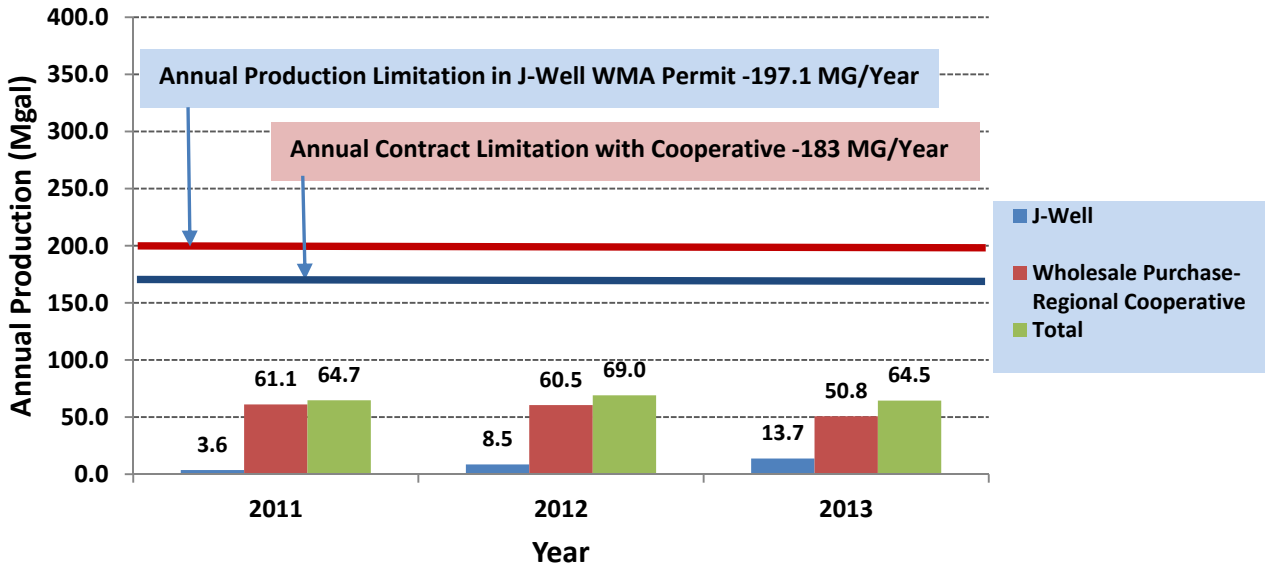
The JBCC wastewater treatment facility has an annual average design flow rating of 300,000 gallons/day, so the water supply from either the J-Well or the UCRWSC is sufficient to meet the entire available capacity at the wastewater treatment facility.

In summary, JBCC can meet all the required demands in the system with either the J-Well or the UCRWSC interconnection. Both of the sources are not needed other than providing complete redundancy.

If the JBCC choose to consume the remaining capacity of the water supply through development, the constraint on the water supply would be the capacity of the current wastewater treatment facility not the permit or purchase agreement with the UCRWSC.

The annual production values from each source, as well as the annual production/contract limits from each source, are presented in **Figure 5-6**.

Figure 5-6 – Annual Production Limitations for J-Well and UCRWSC



5.4.1.2 Maximum-Day Demands

Maximum-day demands or production from the two water supplies were not made available for review. From a water supply perspective, the UCRWSC agreement allows for a maximum-day purchase of 500,000 gallons on any given day during the year as previously described.

For the J-Well, the Water Management Act registration statement has no limits on maximum-day pumpage as long as the annual withdrawal volume of 197.1 Mgal is not exceeded. The maximum-day production rate from the J-Well is constrained by the well capacity and pump, currently limited to about 1,400 gpm or 2.0 mgd. If the well pump is operating at maximum speed and the full allocation from the UCRWSC is used, the JBCC supply can produce 2.5 mgd.

The maximum-day capacity of the JBCC wastewater treatment is about 800,000 gal/day. If the JBCC chooses to consume the remaining capacity of the wastewater treatment facility through development, the J-Well would be required as a peaking source to meet these demands. At this juncture, the demands in the system can be met under this design condition with either source of supply under average-day demand conditions.

5.4.1.3 Conditional Assessment of J-Well

The J-Well was substantially renovated in the 1990's. The well now requires routine maintenance to chemical feed systems, maintenance of the building and routine cleaning of the well screen. No major capital investment is needed over the next 20 years to comply with new regulations or for a major rehabilitation of the pumping station.

5.4.1.4 Supply Redundancy

The UCRWSC is supplied by three wells. The UCRWSC supply has inherent supply and well redundancy to the wholesale customers including the JBCC. Although the J-Well does provide direct mechanical redundancy, the well is not needed to meet the projected demands in the JBCC system. The well also provides redundancy back to the UCRWSC and is a registered water supply with likely regional value.

The J-Well has much greater value as a potential regional water supply source. It is recommended that this be explored further to assess the true value of this asset. Strictly from a water supply perspective the J-Well is costly and is not needed to meet the projected demands.

5.4.2. Storage Evaluation

5.4.2.1 Storage Quantity Required

The JBCC owns and operates two distribution storage facilities as previously described. System storage is necessary for the following reasons:

- Storage should be designed to provide all demands which exceed the maximum day average flow rate. The volume of storage which is depleted during the daytime, peak flow periods is refilled during the lower demand, early morning hours.
- Storage is provided for fire protection. If a fire occurred during the maximum day demand, all the water used to fight the fire would be drawn from storage volume.
- Storage provides water during emergency situations such as power failures, transmission main breaks, etc.
- Storage provides additional volume for pumping during off-peak electrical periods.
- Operating storage is used for cycling pumps during normal daily operation.

All storage components described above should be available while still providing at least 20 psi of pressure in the each pressure zone. This pressure is equivalent to the volume of water stored 46 feet above the highest service. This storage volume is referred to as the available or active storage.

To determine the adequacy of the existing storage volume, an analysis of each of the storage components described was made using projected demands. At this juncture, a projected maximum-day demand of about 390,000 gallons/day was assumed based on observed peaking factors at the wastewater treatment facility. A worst case scenario would dictate that for a fire on the maximum day, the fire flow and hourly fluctuation volume of the available storage should be available simultaneously.

The required storage in the JBCC can be calculated as follows:

1. *Fire Protection Storage Volume* - The volume which should be stored for fire protection should be capable of providing 3,500 gpm for 3 hours or 630,000 gallons. This is the Insurance Services Office (ISO) recommended maximum amount of fire protection necessary for a public water purveyor to supply for a large commercial building. This flow is appropriate for the JBCC.

2. *Equalization Storage for Peak-Hour Storage Fluctuation* - The storage volume necessary to provide the system hourly fluctuation demands was estimated to be 20 percent of the maximum day total demand in total for the entire water system. This equates to a volume of about 80,000 gallons or about twenty percent of the estimated maximum-day demand approximately 390,000 gallons for the entire water system.

3. *Emergency Storage* - Storage should be available to meet emergencies. Because JBCC is interconnected to the UCRWSC and Mashpee and has an emergency generator at the J-Well, the system can meet domestic demands in an emergency without supplemental storage.

The total required active storage volume for the three components described above is 710,000 gallons. The existing active storage volume in the JBCC system is about 800,000 gallons in the storage tanks. Based on this analysis, the JBCC system appears to have adequate storage volume

if both tanks are retained. A brief discussion follows on the condition of the storage tanks and appropriate financial planning and capital reserves to eventually replace these two structures with a similar storage volume.

5.4.2.2 Conditional Assessment and Life Cycle Cost Analysis

The JBCC storage tanks are approaching the end of their useful lives. Although both structures have been recently rehabilitated, the storage tanks are 72 years old and will likely require replacement approaching the next painting cycle in 15 to 20 years.

A recommended approach for storage planning is to allocate a capital reserve account as a sinking fund for maintenance. At this juncture, we would recommend a plan that retains both storage tanks in their current location, which is advantageous for fire flows, and reserve an appropriate amount to rehabilitate both 400,000 gallon facilities. If after 15 years, the condition of the facilities has continued to deteriorate, than the accumulated funds can be supplemented with capital borrowing and the two facilities replaced with a standpipe or elevated tank of similar active storage volume.

Our cost assumptions in establishing the annual maintenance fund, are as follows:

- Estimated cost to rehabilitate each tank $750,000 (2014 dollars)
- Annual inflation rate – 2%
- Anticipated Painting Cycle – 15 years
- Interest rate – 2 %

On this basis, an annual capital reserve amount of $57,000 per tank or $114,000 in total would be required annual to build sufficient funds with inflation to rehabilitate the tanks in 15 years (2029).

5.4.2.3 Storage System Recommendations

On this basis, the JBCC would need to establish a sinking fund in the amount of $57,000/year per storage tank to have sufficient funds to rehabilitate the two storage tanks in 2029 (15 years). At that point in the time, the tanks would be reassessed and either rehabilitated or replaced with supplemental capital funds.

5.5 ALTERNATIVES ANALYSIS

5.5.1. Existing Annual Budget

The existing water O&M costs for the past three years are summarized in **Table 5-1**. This summary was prepared based on information provided by JBCC and includes an adjustment for labor costs. Refer to Sections 1 and 2 for additional information on how labor is accounted for in the budgeting process.

Small capital projects are in this table as O&M expenses. This line item changes year to year based on actual needs at the facility and would typically include such items as contract well cleaning, and other capital items. Routine maintenance items such as chemical feed pump replacement, small mechanical improvements and other similar incidentals are shown as supplies, parts and shop items in the table. Again, the budget for these items will tend to fluctuate year to year based on actual need in a given year.

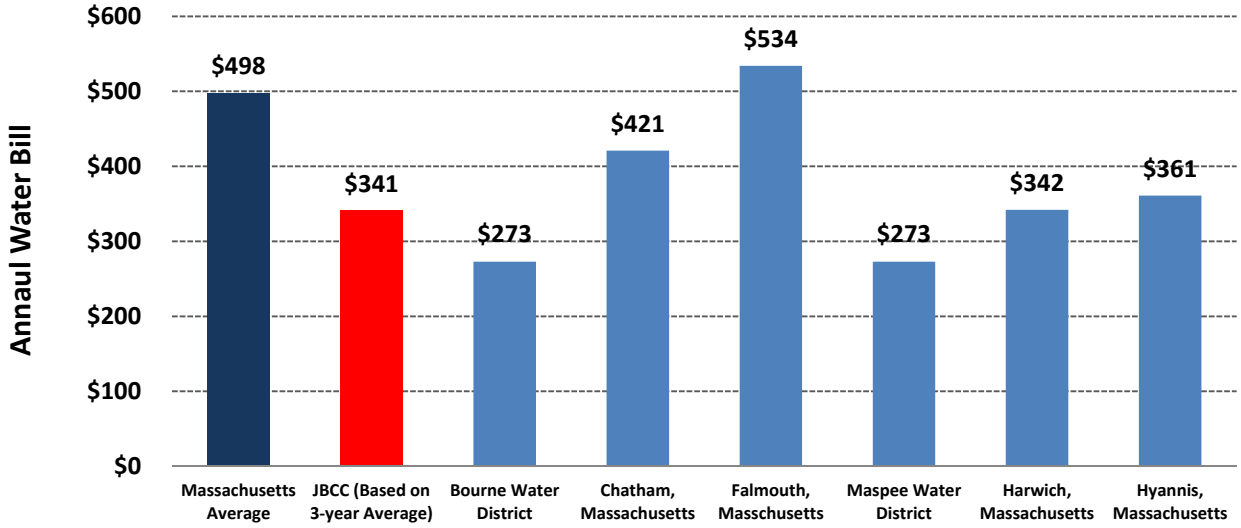
TABLE 5-1
ANNUAL O&M COSTS FOR WATER SYSTEM

Budget Item	2011	2012	2013
Potassium Carbonate	-	$42,553	$17,731
Sodium Hypochlorite	$856	-	-
Sodium Fluoride	$19,903	-	$27,320
Supplies, Parts and Shop Stock	$3,116	$13,799	$13,912
Wholesale Water from UCRWSC	$57,993	$60,461	$50,788
Projects – Sustainment, Repair, Modernization	$12,160	-	$39,655
Natural Gas	$252	$1,070	$982
Electricity	$41,085	$1,746	$3,314
Labor	Not Incl.	Not Incl.	Not Incl.
Total Annual Costs (excl. Labor)	**$141,395**	**$119,628**	**$153,692**
Annual Production (Mgal)	64.7	69.02	64.49
Average-day (gallons/day)	177,300	189,100	176,700
Unit Cost per Mgal (excl. Labor)	$2.18	$1.73	$2.38
Annual Labor with Benefits	-	$342,300	$356,000
Est. Labor for Water (33%)	-	$112,900	$117,500
Total Annual Costs (incl. Labor)	**-**	**$232,500**	**$271,200**
Unit Cost per Mgal (incl. Labor)	-	$3.37	$4.21
Average Unit Cost per Mgal (incl. Labor)	-	$3.79	

5.5.2. Benchmarking Current Production Costs

A biannual water rate survey is conducted in Massachusetts to track municipal water rates in each public or quasi-public water system in the Commonwealth. The last survey was conducted in 2012. The survey tracks residential water costs based on an average annual usage of 120 hundred cubic feet (HCF) or 90,000 gallons per year. In 2012, the average residential water bill in the Commonwealth was $498/year. The median water cost was $476/year. The average operation costs in the last two years including labor is approximately $3.79/Mgal or $341/120 HCF of usage as shown in **Figure 5-7**. It is important to note that this value does not include capital reserves for painting or replacing storage tanks, distribution main replacement costs, projected capital needs at the J-well or debt service to acquire the assets at the JBCC.

Figure 5-7 – Comparison to Annual Water Bills based on 120 HCF of Usage (Existing)



In general, water costs are lower in Cape Cod communities because most communities use groundwater, which is of high quality and requires minimal treatment. Figure 3-8 compares water rates at the JBCC with several local cape communities and with the average residential water-use bill in Massachusetts.

5.5.3. Scenario 2 – Fund Tank Replacement Reserve

Under this scenario, the JBCC would create a sinking fund in the amount of $114,000 annually as a fixed payment for eventual rehabilitation of the two existing storage tanks in year 2029 (15 years). The data suggests that the cost per Mgal will increase to approximately $5.50 per Mgal when this cost is included in the operations budget. This cost would increase the average water bill to about $495 per 120 HCF, close to the state average residential water bill.

5.5.4. Scenario 3 – Fund Service Meter Installation Reserve

The estimated cost to install service meters at each current service connection would be approximately $1,140,000 as previously discussed. If funded over a 20-year period, the annual debt service would be approximately $69,500 at an interest rate of 2% per year. The data suggest that the cost per Mgal will increase to approximately $4.82 per Mgal when this cost is included in the operations budget, assuming no tank reserve. This cost would increase the average water bill to about $434 per 120 HCF, close to the state average residential water bill.

5.5.5. Scenario 4 – Fund Main Replacement Reserve

The JBCC water distribution system contains about 260,000 lineal feet of water mains. The majority of the distribution system mains are 6-inch, 8-inch and 10-inch diameter cast iron and asbestos cement as previously described. Most cast iron water mains have useful lives in excess of 75 years if routinely flushed and maintained. The asbestos cement mains are much less durable but likely have useful lives of about 75 years as well. The useful life of a cast iron main can be extended substantially by installing have new cement liners. For the purposes of this evaluation, we will assume that the entire distribution system will require eventually replacement over a 100-year period, or 1% of the total length of the system per year, or about 2,600 lineal feet of main replacement per year.

Water mains smaller than 8-inch, are normally not installed any longer, because of the small cost differential to increase to 8-inch diameter pipe. An 8-inch diameter main provides tremendous flow benefits over 6-inch diameter mains. Similarly, 10-inch mains are an atypical main size, normally replaced with a 12-inch pipeline. Based on recent bid pricing, our cost model assumes that an average 8-main complete with road restoration, new hydrants, and fittings will cost about $135/foot including engineering and contingencies. On this basis, an annual main replacement budget of $351,000 would be required without annual escalators for inflation.

The data suggests that the cost per Mgal will increase to approximately $9.15 per Mgal when this cost is included in the operations budget, excluding other identified needs such as metering and tank rehabilitation costs. This cost would increase the average water bill to about $823 per 120 HCF, well above the average public water costs in Massachusetts.

It should be recognized that many public water systems do not meet his high standard for full replacement of all pipelines very 100 years or 1% per year. Should the water system assets be required, the rate of pipe replacement should be subject to further discussion. These high costs illustrate the challenge with acquiring and modernizing the JBCC water distribution system. The mains are almost fully depreciated and will now require a routine pipe replacement program to modernize the piping network without the benefit of an existing sinking fund. The analysis

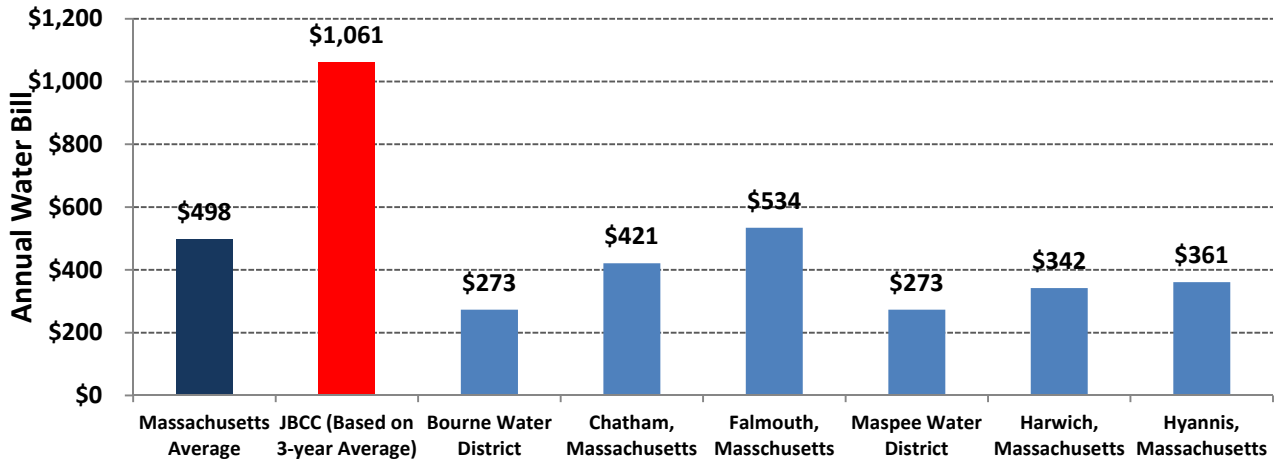
assumes no new debt service to acquire the system and assumes that progressing replacement or rehabilitation of all piping would be completed over the next 100 years at a rate of 2,600 feet per year. It is recommended that a leak detection survey of the entire system be completed initially so that break history and poor quality pipes can be prioritized early in the program.

If the water system were to be acquired, MassDevelopment could establish a rate goal or target water rate for the water system as a way to determine what level of subsidy would be required to fund the needed capital investment in the system.

5.5.6. Scenario 5 – Fund All Recommended Improvements

Scenario 5 includes all the investments included in Scenarios 2 through 4 as well as current operating costs captured in Scenario 1. Under this all-encompassing approach, the cost per Mgal purchased would increase to approximately $11.79 including capital reserve accounts, pipe replacement and metering. Again this cost would exclude any debt service to acquire the water system assets. These data suggest that to properly maintain and operate the current assets, a subsidy from the seller would likely be needed to support revenue requirements if a rate goal somewhat typical for the Commonwealth is desired. Refer to **Figure 5-8** for a comparison to annual water bills in other communities if Scenario 5 was implemented.

Figure 5-8 – Comparison to Annual Water Bills based on 120 HCF for Scenario 5



5.5.7. Summary of Alternatives

Data from the 5 investment alternatives are summarized in **Table 5-2** below. In customary water utility rate making, revenue projections are used to develop a graduated rate scale or cost blocks for various user classes. Normally an increasing block structure is preferred to penalize water high water use and to incentivize water conservation.

TABLE 5-2
PROJECTED ANNUAL REVENUE REQUIREMENT FOR ALTERNATIVES

	Scenario 1 Existing Conditions	Scenario 2 Tank Replacement Reserve	Scenario 3 Meter Installation Reserve	Scenario 4 Main Replacement Reserve	Scenario 5 All Improvements
Current Operating Costs	$251,900	$251,900	$251,900	$251,900	$251,900
Additional Annual Costs Investment	-	$114,000	$69,500	$351,000	$534,500
Total Annual Costs	$251,900	$365,900	$321,400	$602,900	$786,400
Projected Cost per Mgal	$3.79	$5.50	$4.82	$9.04	$11.79
Projected Total Annual Cost per 120 HCF Usage	$341	$495	$434	$823	$1,061

A rate study would develop an appropriate rate schedule and allocate cost based on various cost categories such as minimum quarterly charges, use of consumption costs, meter installation charges and other techniques to distribute and allocate cost. A rate study would be needed if the water system is privatized to determine how the owner of the system wishes to create incentives to encourage or discourage water use. If MassDevelopment intends to take this system over, a more detailed rate study is recommended.

5.5.8. Net Present Value Calculations for Each Scenario

Net present value (NPV) is a useful analysis for comparing the life cycle cost of alternative investments. However, the annual revenue requirements to operate a system and debt service are

what must be supported through water rates. The data in **Table 5-3** are based on the following assumptions:

- Acquire assets at no cost
- 20-year period
- Discount factor of 2%
- No annual escalators included for inflation
- Annual operating costs after year 20 are not included
- No residual value was included for J-Well, storage tanks or distribution system piping

This data will be useful in determining if a subsidy from the JBCC may be needed to support a sustainable water system at water rates that are marketable to outside parties and fair and reasonable when compared to similar water systems.

TABLE 5-3
PROJECTED NET PRESENT VALUE FOR ALTERNATIVES

Improvement Scenario	Projected Annual Revenue Requirements	Estimated Net Present Value (NPV)	Net Increase in NPV from Baseline
Scenario 1 – Baseline Conditions, No Improvements	$251,900	$4,112,000	-
Scenario 2 – Establish Sinking Find for Tank Rehabilitation in 15-years	$365,900	$5,978,000	$1,866,000
Scenario 3 – Install Service Meters on All services	$321,400	$5,254,000	$1,143,000
Scenario 4 – Replace 2,600 feet of Water Mains Each Year	$602,900	$9,986,000	$5,874,000
Scenario 5 – All Improvements made for Scenarios 2-4	$786,400	$12,843,000	$8,731,000

The following strategies should be explored to reduce operating costs and/or to increase revenue to help fund the recommended reserve accounts:

- Reducing reliance on the J-Well to lower operating costs (note that this will be sufficient to cover the additional revenue needs).
- Marketing surplus water from the J-Well to outside partners to generate revenue.

- Transferring ownership of the J-Well and appurtenances to the UCRWSC in exchange for a higher water allowance and a lower "wholesale" rate.

Business case analysis of the water system is beyond the scope of Delivery Order #11 and #12. Based on evaluations to date, it appears that it will be more difficult to fund the water system budget shortfalls given that there is not a large regional water demand (as compared to the anticipated wastewater demand). If MassDevelopment intends to take over the water system, we recommend that it be incorporated into the business case model developed for the wastewater system in order to better assess the necessary user rates.

5.6 REGULATORY CONSIDERATIONS

From a regulatory perspective, the JBCC water supply appears secure for the future. The UCRWSC agreement was enacted through specific legislation and the J-Well supply is registered as a supply with the DEP. Transfer of ownership of the J-Well or sale of water to outside parties may trigger the inter-basin transfer regulations and MEPA and should be investigated before any of these actions are pursued. Refer **Section 2.7** for further discussion of regulatory issues.

6 CONCLUSIONS AND RECOMMENDATIONS

6.1 WASTEWATER SYSTEM

Based on our evaluations, we offer the following conclusions and recommendations regarding the JBCC wastewater system:

- The collection system is reportedly in fair to poor condition.
    a. Based on pipe material and age, approximately 15% of the collection system piping will exceed its design life in the next 10 years (i.e., asbestos cement and orangeburg pipe) and an additional 80% of the collection system piping will exceed its design life within 20 years (i.e., vitrified clay). The system will require consistent investment over time to maintain the current level of service.
    b. The collection system is extensive and was built when there were 70,000 users on-site; whereas, there are currently approximately 3,500 users. The extent of the collection is much larger than is currently needed; however, the system is adequate to meet the existing JBCC needs. Portions of the system could be capped, if desired, to minimize long-term asset management costs.
    c. The collection system exhibits evidence of *inflow* (i.e., water entering the system typically during and immediately following storm events), which reduces available capacity, as noted below.
    d. Staffing limitations force the operators to focus on the WWTF and not on the collection system. The operators appear to have lesser knowledge of the condition of the collection system.

- The WWTF is in good condition.
    a. The WWTF has approximately **157,000 gpd (annual average)** of unused capacity.
    b. Effluent from the WWTF has exceeded the GWDP limits for nitrate and/or total nitrogen in 11 of the 27 months between January 2012 and April 2014. These

exceedences are related to the variability of influent wastewater temperatures, flows and loads associated with base operations and with infiltration/inflow.

c. Some capital improvements (i.e., influent equalization and supplemental carbon feed systems) are warranted in order to improve operational flexibility for GWDP compliance.

d. The WWTF remaining capacity could be made available to additional users on JBCC, to neighboring municipalities or to septage haulers after baseline capital improvements are implemented to accept additional flows.

- The effluent forcemain piping and structures are reportedly in good physical condition; however, based on operator input, the effluent forcemain appears to have capacity limitations related to apparent hydraulic transient conditions which occur when more than one effluent pump is running. Capital improvements may be needed in order to restore/provide additional capacity. At a minimum, additional study is warranted to determine the specific cause of the capacity limitations. We have included costs for additional study and for limited capital improvements to address forcemain capacity concerns.

- The effluent disposal system is in good condition.

  a. The effluent disposal system has approximately 157,000 gpd of additional capacity on an annual average basis. On a maximum day basis (due to the impacts of inflow), the effluent disposal system has approximately 285,000 gpd of additional capacity. Given that the existing peaking factor for peak to average flows is 3.8:1 (again, due primarily to the impacts of inflow), the *effective capacity* is approximately **75,000 gpd (annual average)**. Refer to **Section 2** for additional information. Available capacity can be made available to neighboring communities or users on the base.

  b. The *effective capacity* can be increased back to the full unused capacity with aggressive inflow control**.** The *effective capacity* at the effluent disposal system can also be increased within the existing GWDP by: addressing the effluent

forcemain capacity limitations; bringing on customers with low wastewater flow peaking factors; and/or by providing equalization at the WWTF. It is expected that DEP would be receptive to these types of measures.

c. The capacity could potentially be further increased by re-rating the RIBs through a GWDP revision. This would require hydrogeologic study and DEP review and approval. Re-rating the RIBs will be more difficult to attain than addressing the effective capacity as described above.

- There are numerous potential risks associated with the take-over of a wastewater utility such as the JBCC wastewater system; however, it is important to understand that these risks are inherent to sewerage infrastructure and are similar to those faced by many small municipal wastewater systems throughout New England. A summary of these risks is presented in **Table 4-1**.

- There are several JBCC-specific items which MassDevelopment should consider in its negotiations with USAF/ANG, including items such as segregating liability related to legacy pollutants, obtaining consent for "right of access to inspect" through the Sewer Use Ordinance and Industrial Pre-Treatment Program, etc. These are described in **Section 4**.

- MassDevelopment has a goal of creating a sustainability utility and rate structure within a 10-year timeframe. MassDevelopment also has a goal of ultimately transferring ownership to another municipal or quasi-municipal entity; however, MassDevelopment intends to own and operate the wastewater system until such time as the subsequent owner is identified and asset transfer is completed.

- Based on the steady-state balance sheet analysis described in **Section 3**, MassDevelopment should not pay for the wastewater system assets. Additional information and conclusions are presented in Section 3. Key conclusions from this analysis are:

a. A subsidy is required in the first 5 years, declining from the first to the fifth year.
b. For Alternative 1D, net surplus revenue begins between Year 6 and 8.
c. For Alternative 2D, net surplus revenue begins between Year 12 and 14.
d. A sensitivity analysis shows that the net surplus revenue generated from the various scenarios will improve (or not worsen) if the user rates and operational costs are increased with inflation.

- If MassDevelopment can support the capital investments described herein, then then we recommend implementing **Alternative 1D** (i.e., baseline improvements with upgrades to accept some new sewage as well as septage and effluent disposal). Alternative 1D has a higher net present value, has less risk and fewer regulatory, institutional and financial complexities.

- If MassDevelopment can secure binding commitments from potential new users (commitment to connect, financially contribute, pay user rates and abide by the sewer use ordinance), then the JBCC wastewater system could be expanded to **Alternative 2D** (i.e., 50% capacity expansion with upgrades to accept new sewage, septage and effluent disposal) now or in the future. One example would be Mashpee securing Town Meeting approval(s) to proceed to implementation of its CWMP.

6.2 WATER SYSTEM

Based on our evaluations, we offer the following conclusions and recommendations regarding the JBCC water system:

- Water Supply
    a. The J-well and appurtenances are in good condition and should be serviceable for another 15 to 20 years without the need for major capital expenditures.
    b. The UCRWSC interconnection meter and appurtenances were not inspected but are relatively new and it is our understanding that they are in good working order. The meter should be calibrated every 3 to 5 years.

c. The J-Well and the interconnection with the UCRWSC are each sufficient to meet the needs of the JBCC. Having both supplies available provides redundancy and protects the JBCC system from having the J-Well declassified as an "inactive supply" through lack of use.

d. The J-Well is a large, relatively high quality supply operating through a DEP Registration Statement. MassDevelopment could sell reserve supply capacity to other surrounding local utilities as a source of revenue without compromising safe delivery of water within the JBCC geographic boundaries. Alternatively, MassDevelopment could transfer ownership of the J-well to the UCRWSC in exchange for a higher water supply allocation through the interconnection. The needs of the UCRWSC and the surrounding municipalities, utilities and/or industrial/commercial partners should be assessed.

- Water Storage Tanks

  a. The two 400,000-gallon water storage tanks are nearly 75 years old. Both tanks will have new coating systems by the end of next year and will be ready for the next maintenance cycle. Both tanks will likely require replacement within 15 years. This type of elevated storage tank is outdated and can likely be replaced in the future with a standpipe, or modern elevated tank. We recommend establishing a capital reserve account in the amount of $57,000 per year per tank to create a sufficient fund to rehabilitate the tanks in 15 years.

  b. The active storage volume in the two storage tanks is about 800,000 gallons. From a fire suppression perspective, the storage tanks have adequate volume and elevation to meet the needs at JBCC.

- Water Distribution System

  a. The water distribution system is comprised of 49 miles of water mains. The system consists primarily of small diameter 6, 8 and 10-inch mains were constructed in the 1940s and 1950s. The mains are primarily cast iron and asbestos cement pipelines. Most mains date back to the early inception of the

system; records are poor and leaks have become more common in recent years. A pipe renewal program is needed to begin modernizing the distribution system.

b. We recommend establishing an annual replacement program of 2,600 feet of new main a year will result in complete replacement of the distribution system in 100 years. Although recent evidence suggests that some older cast iron mains can remain serviceable for more than 100 years, the system must catch up from lack of maintenance. The estimated cost to replace mains at this rate is $351,000 per year.

c. We recommended conducting a leak detection survey of the entire distribution system in order to establish priority for main renewals in the JBCC water system.

- Service Metering
  a. Presently, service connections to all buildings and structures are unmetered. Water use is estimated using a demand algorithm developed by JBCC utility managers.
  b. We recommend that service meters be installed at each structure, including a new meter, meter horn to mount the meter and a touchpad meter reading service mounted on the outside of each building. Radio read technology is the state of the art approach in water metering but would be more costly than the basic system proposed herein. The estimated cost for a basic meter installation for the estimated 380 service connections in the JBCC system is $1,140,000 (based on a $3,000 allocation per service connection).

- Budgeting for Recommended Reserve Accounts
  a. We recommend the establishment of several reserve accounts (i.e., for storage tanks, service meters and main replacement/rehabilitation) in order preserve and maintain the water system assets. Funding these reserve accounts would result in a significant increase in the annual budget requirements for the water system. The existing water system budget is approximately $252,000 per year. If all of these

reserve accounts were funded to the suggested levels, the annual budget would increase to approximately $534,000.

b. This would increase the cost of service from $3.79/Mgal to $11.79/Mgal. Based on 120 hundred cubic feet (HCF) of consumption, this would equate to an annual bill ranging from $340 to $1,060, respectively. By way of comparison, the average water bill in the Commonwealth of Massachusetts for 120 HCF of consumption is about $498/year.

- Opinion of Water System Valuation
    a. Given the condition of the existing water system and the upcoming asset management needs, MassDevelopment should not pay for the water system assets.
    b. Further, the water system should not be acquired without the wastewater system as the wastewater system has a larger user base and has a greater ability to gather revenue from regional partners to help supplement reserve accounts and maintain stable rates.
    c. If the water system assets were to be transferred to MassDevelopment at no cost, the operating costs plus the recommended investments would require revenue for water sales to be increased. This would require rate increases to existing military and non-military users.
    d. Selling surplus water outside JBCCs boundaries could present an opportunity to raise revenue to offset costs or reduce the need for a subsidy. Transferring ownership of the J-Well and appurtenances to the UCRWSC in exchange for a higher water allowance and a lower "wholesale" rate may also provide a similar benefit.
    e. While sale of wastewater capacity will produce revenue sufficient to fund *wastewater reserve accounts*, it will not produce revenue sufficient to also fund *water reserve accounts*. The "optimized best case" sewer user rates (refer to Section 4) provide the most net surplus revenue.

- Opinion of Water System Valuation
    a. We recommend conducting a more detailed evaluation to develop an appropriate rate schedule and allocate cost based on various cost categories such as minimum quarterly charges, use of consumption costs, meter installation charges and other techniques to distribute and allocate cost. In customary water utility rate making, revenue projections are used to develop a graduated rate scale or cost blocks for various user classes. Typically, an increasing block structure is preferred to incentivize water conservation.

6.3 IMPLEMENTATION STEPS

6.3.1. Wastewater System

As MassDevelopment considers assuming ownership and responsibility for the JBCC wastewater system, we recommend the following key implementation steps for Scenario 1D:

1. Meet with JBCC to provide an informal status update on the project.
2. Develop a negotiating strategy and initial proposal.
3. Meet with the USAF and ANG to discuss an initial draft proposal.
    a. Define military protocols and timeframes for review and approval of a subsequent formal proposal.
    b. Request preliminary review and comments from the military on the form of the proposal and preliminary indication of the willingness of the USAF to enter formal negotiations for the transfer of the system under the terms of the proposal.
4. Determine eligibility for state SRF loans and develop financing plan
5. Meet with interested towns, DEP and Cape Cod Commission to define issues, implementation processes, and timeframe for connecting to the JBCC system. Request a letter of interest or commitment from selected neighboring municipalities.
6. Draft, modify and execute a joint Memorandum of Understanding (MOU) among appropriate parties (including the military) that defines the interests, process, roles, responsibilities, assumptions and funding framework for jointly investigating beneficial options for the JBCC wastewater system.

7. Coordinate and/or conduct additional targeted studies on wastewater system components for the purpose of mitigating risk (i.e., by refining cost estimates or by confirming revenue sources). Specific studies should be considered include field inspections of select portions of the collection system, field inspections of select portions of the effluent forcemain, operational reviews at the WWTF, "re-rating" analysis for the RIBs, determination of the appropriate effluent limits to be met by new "effluent disposal users" as well as follow-on rate work to refine the business case model. Funding for the studies would be as defined in the MOU.
8. Update the initial proposal based on findings of additional studies and enter negotiations with the USAF and ANG.
9. Evaluate the benefits of using a design-build-operate (D/B/O) contract for project implementation. Solicit or otherwise develop more detailed preliminary "bids" or estimates for contract operations of the systems under various investment and operating scenarios.
10. Refine the business plan to reflect actual needs and interests as defined by the towns, including revised flows, loads, capital and operating costs, connection fees, user fees, governance structure, financing methods and other factors that provide a firm basis for town decisions based on the particular wastewater services being provided to each town through the plan.
11. Apply for interim and permanent financing for the upgrades under the authority of the agreed-upon governing entity.
12. Draft and enact legislation to authorize use D/B/O procurement and implementation for the project improvements and operations.
13. Refine the risk management plan for MassDevelopment based on studies, discussions and other information.
14. Enter final negotiations with the USAF for transfer of the system. Confirm terms, conditions, agreements and assumptions. Finalize and execute agreement between MassDevelopment and the USAF for transfer of facilities. Conduct transfer of the assets and permits.

15. Initiate procurement for a contract operator or D/B/O contractor for the JBCC wastewater system. D/B/O Contractor will develop and attain regulatory approval of Sewer Use Ordinance and Industrial Pre-Treatment Program documents. Issue draft industrial user permits to applicable existing users.

For Scenario 2D, we recommend an additional step prior to committing to capital project(s) in order to increase capacity. Specifically, securing verification in the revised business plan of the viability and benefit of one or more joint wastewater arrangements (e.g. wastewater district, IMAs), draft, negotiate and execute agreements, enact legislation and complete other legal and administrative actions necessary to bind parties to their responsibilities under the plan. This step would include the necessary town meeting(s) and other approvals necessary to commit funding.

6.3.2. Water System

As MassDevelopment considers assuming ownership and responsibility for the JBCC water system, we recommend the following key implementation steps:

1. If the wastewater system transfer appears likely:
   a) Expand the wastewater business case model to include the water system costs and revenues;
   b) Meet with the UCRWSC, DEP and the Cape Cod Commission to discuss the potential to transfer ownership of the J-well to the UCRWSC and increase of the JBCC water allocation. Potentially meet with neighboring municipalities to assess their needs for supplemental water supply under MassDevelopment ownership. Request a letter of interest or commitment from the relevant entities.
2. Develop a negotiating strategy and initial proposal for the water system.
3. Meet with the USAF and ANG to discuss an initial proposal.
4. If MassDevelopment, USAF and ANG are in general agreement with the initial draft proposal, align the water system acquisition tasks with the wastewater system acquisition tasks as described in Section 1.6.1.

6.3.3. Implementation Timeline

A preliminary implementation timeline is presented in **Table 6-1**. The timeline shows a range of dates for each major action item. In terms of the range of dates, Scenario 1D has less uncertainty than Scenario 2D primarily because it does not rely on appropriations from a municipal entity.

TABLE 6-1
IMPLEMENTATION TIMELINE

Implementation Task	Timeline
Develop a negotiating strategy and initial proposal for the wastewater system. Meet with USAF/ANG to discuss initial proposal. Develop a preliminary agreement.	2015
Meet with neighboring municipalities, CCC and DEP to define a framework for regional use of the wastewater system. Request a letter of interest or commitment from the relevant entities.	2015
Meet with the Upper Cape Regional Water Supply Cooperative, CCC and DEP to discuss potential transfer of ownership of the J-well to the UCRWSC. Request a letter of interest or commitment.	2015
Determine SRF loan eligibility for the wastewater system.	2015
Develop Memorandum of Understanding among all interested parties for the wastewater and water systems.	2015
Complete Engineering Studies (wastewater and water)	2015 to 2016
Gather financial commitments from applicable potential users	2015 to 2020 (1)
Evaluate D/B/O procurement method. Draft and enact legislation as appropriate. Procure contractor operator.	2015 to 2016
Complete legal transfer of ownership	2016 to 2017
Design, construct and commission upgrades	2016 to 2020 (1)
Collect Connection Fees from New Users	2016 to 2020 (1)
Begin Loan Repayment on New Debt	2018 to 2021 (1)
Receive Flow from New Users	2018 to 2021 (1)

Notes:1) Financial commitments from municipalities are subject to Town Meeting appropriation which may take several years.

Dear Groundwater Discharge Permittee:

I am writing to inform you of recent legislative developments and how they affect your Groundwater Discharge Permit renewal timeline.

In August 2010, Governor Patrick signed Chapter 240 of the Acts of 2010 into law. Section 173 of this Act is known as the Permit Extension Act ("PEA" or "the Act"). In August 2012, Governor Patrick signed Chapter 238 of the Acts of 2012, which included two sections amending the PEA. As amended, the Act automatically extends (with limited exceptions), for four years beyond its otherwise applicable expiration date, any permit or approval for the use or development of property that was "in effect or existence" during the qualifying period beginning on August 15, 2008, and extending through August 15, 2012.

The Permit Extension Act's provisions have extended the term of your Groundwater Discharge Permit, # 41-3 issued to Otis AFB in Sandwich, as it was in effect during the specified time period. This permit will now expire on 4/23/2018. **Please do not submit a permit renewal application at this time. Your renewal application for this permit will now be due on 10/25/2017, six months prior to the new expiration date.** We apologize for any time that you may have spent preparing your permit renewal application and suggest you hold on to those materials developed to date in anticipation of your future filing. Until then your existing permit continues in effect.

Please contact Marybeth Chubb at (617) 556-1029 or Linda Barba at (617) 556-1150 if you have any questions regarding your permit's status or the effect of the Permit Extension Act.

Sincerely,

David R Ferris

RE: BRPWP12, Otis ANG Base Wastewater Treatment Facility
Permit No.: 41-3
Transmittal No. W227706

Dear Ms. Ware:

The Department has completed its review of your request for a change to the existing permit to discharge treated wastewater from the facility located at the Otis ANG Base Wastewater Treatment Facility to the ground and after due public notice, hereby issues the enclosed final permit.

The Department, during the public comment period, received no comments objecting to the issuance or terms of this permit. Therefore, in accordance with 314 CMR 2.08, the permit becomes effective upon issuance.

Parties aggrieved by the issuance of this permit are hereby advised of their right to request an Adjudicatory Hearing under the provision of Chapter 30A of the Massachusetts General Laws and 314 CMR 1.00: Rules for the Conduct of Adjudicatory Proceeding. Unless the person requesting the adjudicatory hearing requests and is granted a stay of the terms and conditions of the permit, the permit shall remain fully effective.

Should you have any questions regarding this matter, please contact Christos Dimisioris at (508) 946-2736.

Very truly yours,

for Brian A. Dudley

GROUNDWATER DISCHARGE PERMIT

Name and Address of Applicant: ***102nd Intelligence Wing, 197 Granville Avenue, Box 46, Otis Air National Guard, MA 02542.***

Date of Application:	***July 10, 2008***
Application/Permit No.	***41-3***
Date of Issuance:	***April 23, 2009***
Date of Expiration:	***April 23, 2014***
Effective Date:	***April 23, 2009***

AUTHORITY FOR ISSUANCE

Pursuant to authority granted by Chapter 21, Sections 26-53 of the Massachusetts General Laws, as amended, 314 CMR 2.00, and 314 CMR 5.00, the Massachusetts Department of Environmental Protection (the Department) hereby issues the following permit to: 102nd Intelligence Wing (hereinafter called "the permittee") authorizing discharges from the on-site wastewater treatment facility to the ground located at 971 South Outer Road, Otis Air National Guard Base, MA 02542, such authorization being expressly conditional on compliance by the permittee with all terms and conditions of the permit hereinafter set forth.

I. SPECIAL CONDITIONS

A. Effluent Limits

The permittee is authorized to discharge into the ground from the wastewater treatment facilities for which this permit is issued a treated effluent whose characteristics shall not exceed the following values:

Effluent Characteristics	Discharge Limitations
12 month moving average flow	360,000 GPD
Maximum day flow	840,000 GPD
Oil and grease	15 mg/l
Total Suspended Solids (TSS)	30 mg/l
Total Nitrogen (NO_2 + NO_3 + TKN)	10 mg/l
Nitrate-Nitrogen	10 mg/l
Biochemical Oxygen Demand, 5-day @20°C (BOD_5)	30 mg/l
Fecal Coliform	200 colonies / 100 ml

a) The pH of the effluent shall not be less than 6.5 nor greater than 8.5 at any time.

b) The discharge of the effluent shall not result in any demonstrable adverse effect on the groundwater or violate any water quality standards that have been promulgated.

c) The monthly average concentration of BOD and TSS in the discharge shall not exceed 15 percent of the monthly average concentrations of BOD and TSS in the influent into the permittee's wastewater treatment facility.

d) When the average annual flow exceeds 80 percent of the permitted flow limitations, the permittee shall submit a report to the Department describing what steps the permittee will take in order to remain in compliance with the permit limitations and conditions, inclusive of the flow limitations established in this permit.

B. Monitoring and Reporting

1) INFLUENT:

The permittee shall monitor and record the quality of the **influent** waste stream to the facility according to the following schedule and other provisions:

Parameter	Minimum Frequency of Analysis	Sample Type
BOD_5	Monthly	24-Hour Composite
Total Suspended Solids	Monthly	24-Hour Composite
Total Solids	Monthly	24-Hour Composite
Ammonia Nitrogen	Monthly	24-Hour Composite

EFFLUENT:

The permittee shall monitor and record the quality and quantity of **effluent** at the effluent pump chamber to the leaching area according to the following schedule and other provisions:

Parameter	Minimum Frequency of Analysis	Sample Type
Flow	Daily	Meter reading
pH	Daily	Grab
Total Suspended Solids	Monthly	24-Hour Composite
Total Solids	Monthly	24-Hour Composite
Oil & Grease	Monthly	Grab
BOD_5	Monthly	24-Hour Composite
Nitrate Nitrogen	Monthly	24-Hour Composite
Total Nitrogen (NO_2 + NO_3 + TKN)	Monthly	24-Hour Composite
Fecal Coliform	Monthly	Grab

Total Phosphorus (as P) [2]	Monthly	Grab
Orthophosphate (as P) [2]	Monthly	Grab
Volatile Organic Compounds[1]	Monthly	Grab

[1]USEPA Method #624
[2]After one full year of monitoring the Total Phosphorus and Orthophosphate results, the Department may determine, upon the request of the permittee, that the frequency of monitoring may be reduced if, in the judgement of the Department, the results of the sampling indicate that existing phosphorus levels will not adversely impact downgradient receptors.

2) The permittee shall sample the upgradient monitoring well: MW16 and the downgradient monitoring wells MW13, MW14 and MW15 as shown on a plan titled "Otis Air National Guard Effluent Force Main and Infiltration Basins" sheet 4 of 55, dated August 12, 1993. Labels identifying each monitoring well's identification in accordance with the above-referenced approved plan shall be affixed to the steel protective casing of each monitoring well.

The permittee shall monitor, record and report the quality of water in the monitoring wells according to the following schedule and other provisions:

Parameter	**Frequency of Analysis**
Static Water Level[1]	Monthly
Specific Conductance	Monthly
pH	Monthly
Total Nitrogen (NO_2+NO_3+TKN)	Quarterly
Nitrate-Nitrogen	Quarterly
Total Phosphorus (as P) [2]	Quarterly
Orthophosphate (as P) [2]	Quarterly
Volatile Organic Compounds[3]	Annually

[1]Static Water Level shall be expressed as an elevation and shall be referenced to the surveyed datum established for the site. It shall be calculated by subtracting the depth to the water table from the surveyed elevation of the top of the monitoring well's PVC well casing/riser.

[2]After one full year of monitoring the Total Phosphorus and Orthophosphate results, the Department may determine, upon the request of the permittee, that the frequency of monitoring may be reduced if, in the judgement of the Department, the results of the sampling indicate that existing phosphorus levels will not adversely impact downgradient receptors.
[3]USEPA Method #624

3) Any grab sample or composite sample required to be taken less frequently than daily shall be taken during the period of Monday through Friday inclusive. All composite samples shall be taken over the operating day.

The permittee shall submit all monitoring reports within 30 days of the last day of the reporting month. Reports shall be on an acceptable form, properly filled and signed and shall be sent to:

Department of Environmental Protection
Southeast Regional Office
20 Riverside Drive
Lakeville, MA 02347

Director of Watershed Permitting
Department of Environmental Protection
Watershed Permitting Group
One Winter Street
Boston, MA 02108

Bourne Board of Health
24 Perry Avenue
Buzzards Bay, Bourne, MA 02532

Mashpee Health Department
16 Great Neck Road North
Mashpee, Massachusetts 02649

Sandwich Board of Health
16 Jan Sebastian Drive
Sandwich, Massachusetts 02563

Submission of monitoring reports in electronic format is available through eDEP and serves as data submission to both the Regional and Boston offices. To register for electronic submission go to: *http://www.mass.gov/dep/service/compliance/edeponlf.htm*

C. Supplemental Conditions

1. The permittee shall notify the Department at least thirty (30) days in advance of the proposed transfer of ownership of the treatment works for which this permit is written. Said notification shall include a written agreement between the existing and new permittees containing a specific date for transfer of permit, responsibility, coverage and liability between them.
2. A staffing plan for the treatment works shall be submitted to the Department once every two years and whenever there are staffing changes. The staffing plan shall include the following components:
   a) The operator(s)'s name(s), operator grade(s) and operator license number(s);
   b) The number of operational days per week;
   c) The number of operational shifts per week;
   d) The number of shifts per day;
   e) The required personnel per shift;
   f) Saturday, Sunday and holiday staff coverage;
   g) Emergency operating personnel
3. The permittee is responsible for the operation and maintenance of all sewers, pump stations, and treatment units for the permitted facility, which shall be operated and maintained under the direction of a properly certified wastewater operator.
4. The permittee shall contract to have any and all solids and sludges generated by the treatment works for which this permit is issued removed off site by a properly licensed waste hauler for disposal at an EPA/DEP approved facility. The name and license number of the hauler along with the quantity of wastes removed and the date(s) of removal shall be reported by the permittee in writing to the Department.
5. Operation and maintenance of the proposed facility must be in accordance with 314 CMR 12.00, "Operation and Maintenance and Pretreatment Standards for Wastewater Treatment Works and Indirect Discharges", and, 257 CMR 2.00, "Rules and Regulations for Certification of Operators of Wastewater Treatment Facilities.
   a. The facility has been rated (in accordance with 257 CMR 2.00), to be a Grade 5 facility. Therefore, the permittee shall provide for oversight by a Massachusetts Certified Wastewater Treatment plant operator (Chief Operator) Grade 5 or higher. The permittee will also provide for a backup operator who shall possess at least a valid Grade 5 license.
   b. The date and time of the operator's inspection along with the operator's name and certification shall be recorded on the required monthly monitoring reports.
6. If the operation and maintenance of the facility is contracted to a private concern, the permittee shall submit a copy of the contract, consistent with what is required by the approved Operation & Maintenance manual and signed only by the contractor, to the appropriate MassDEP Regional Office within thirty days of permit issuance. Along with the contract, a detailed listing of all contract operation obligations of the proposed contractor at other facilities shall also be submitted.
7. Any additional connections to the sewer system, beyond the facility as described on the approved plans shall be approved by MassDEP and the local Board of Health prior to the connection.

8. All tests or analytical determinations to determine compliance with permit standards and requirements shall be done using tests and procedures found in the most recent version of *Standard Methods for the Examination of Water and Wastewater* and shall be performed by a Massachusetts certified laboratory.
9. The permittee shall notify the Department, in writing, within thirty (30) days of the following events:
   a. Any interruption of the treatment system operation, other than routine maintenance.
   b. Final shutdown of the treatment system.
10. Simultaneously with the permit renewal application at year fifteen (2014) following the initiation of plant operations, the permittee shall submit two reports to the Department for its review and approval:
   a. an engineering report, prepared by a registered professional engineer, that outlines in sufficient detail what modifications (if any) to the facility or other changes are required to insure that the facility can remain in compliance with its GWDP and other applicable requirements through the next 5 year permit term (year 2019) and beyond; and
   b. a financial plan that contains the cost estimates for implementing the facility modifications or other changes identified in the engineering report, and describes and demonstrates, how and when the permittee will finance the needed facility modifications or other changes.
11. In the event that effluent limits are not met, or the groundwater quality in the down-gradient monitoring wells does not meet the groundwater quality standards for Class I groundwaters, the permittee may be obligated to modify, supplement or replace the permitted treatment process so as to ensure compliance with the groundwater quality standards.

D. Appeal Rights

This Permit is an action of the Department. Any person aggrieved by this action may request an Adjudicatory Hearing. A request for a hearing must be made in writing and postmarked within thirty (30) days of the Permit issuance date. Under 310 CMR 1.01(6)(b), the request must state clearly and concisely the facts, which are the grounds for the request, and the relief sought.

The Hearing request along with a valid check payable to the Commonwealth of Massachusetts in the amount of one hundred dollars ($100.00) must be mailed to:

Commonwealth of Massachusetts
Department of Environmental Protection
P.O. Box 4062
Boston, MA 02211

The request will be dismissed if the filing fee is not paid, unless the appellant is exempt or granted a waiver as described below. The filing fee is not required if the appellant is a city or town (or municipal agency), county, or district of the Commonwealth of Massachusetts, or a municipal housing authority. The Department may waive the adjudicatory hearing filing fee for a

person who shows that paying the fee will create an undue financial hardship. A person seeking a waiver must file, together with the hearing request as provided above, an affidavit setting forth the facts believed to support the claim of undue financial hardship

II. GENERAL PERMIT CONDITIONS

The following conditions apply to all permits:

1. No discharge authorized in the permit shall result in a violation of the Massachusetts Surface Water Quality Standards (314 CMR 4.00) or the Massachusetts Ground Water Quality Standards (314 CMR 6.00), or any amendments thereto. Upon promulgation of any amended standard, this permit may be revised or amended in accordance with such standard and 314 CMR 2.10 and 3.12 or 5.12. For purposes of determining compliance with ground water quality standards, a violation of the ground water quality standards, and the discharge permit, will be determined to occur when any parameter measured in any downgradient well exceeds the applicable criteria listed in 314 CMR 6.06. In those cases where it is shown that a measured parameter exceeds the applicable criteria listed in 314 CMR 6.06 at the upgradient monitoring well, a violation of the ground water quality standards and the discharge permit will be determined to occur when it is shown that a measured parameter in any downgradient well exceeds the level of that same measured parameter in the upgradient well for the same sampling period. A statistical procedure approved by the Department shall be used in determining when a measured parameter exceeds the allowable level.
2. Duty to comply. The permittee shall comply at all times with the terms and conditions of the permit, 314 CMR, M.G.L. c. 21, §§ 26 through 53 and all other applicable state and federal statutes and regulations.
3. Standards and prohibitions toxic pollutants. The permittee shall comply with effluent standards or prohibitions established under PL 92-500, § 307(a) for toxic pollutants within the time provided in the regulations that establish these standards or prohibitions, even if the permit has not yet been modified to incorporate the requirement.
4. Proper operation and maintenance. The permittee shall at all times properly operate and maintain all facilities and equipment installed or used to achieve compliance with the terms and conditions of the permit, and in accordance with 314 CMR 12.00.
5. Duty to halt or reduce activity. Upon reduction, loss, or failure of the treatment facility, the permittee shall, to the extent necessary to maintain compliance with its permit, control production or discharges or both until the facility is restored or an alternative method of treatment is provided. It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of the permit.
6. Power Failure. In order to maintain compliance with the effluent limitations and prohibitions of this permit, the permittee shall either:
   a. provide an alternative power source sufficient to operate the wastewater control facilities; or

b. halt, reduce or otherwise control production and/or all discharges upon the reduction, loss, or failure of the primary source of power to the wastewater control facilities.

7. Duty to mitigate. The permittee shall take all reasonable steps to minimize or prevent any adverse impact on human health or the environment resulting from non-compliance with the permit.

8. Duty to provide information. The permittee shall furnish to the Department within a reasonable time any information which the Department may request to determine whether cause exists for modifying, revoking and reissuing, or terminating the permit, or to determine whether the permittee is complying with the terms and conditions of the permit.

9. Inspection and entry. The permittee shall allow the Department or its authorized representatives to:
   a. Enter upon the permittee's premises where a regulated facility or activity is located or conducted, or where records required by the permit are kept;
   b. Have access to and copy, at reasonable times, any records that must be kept under the conditions of the permit;
   c. Inspect at reasonable times any facilities, equipment, practices, or operations regulated or required under the permit; and
   d. Sample or monitor at reasonable times for the purpose of determining compliance with the terms and conditions of the permit.

10. Monitoring. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity. Monitoring must be conducted according to test procedures approved under 40 CFR Part 136 unless other test procedures are specified in the permit.

11. Record keeping. The permittee shall retain records of all monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of all reports required by the permit, and all records of all data used to complete the application for the permit, for a period of at least three years from the date of the sample, measurement, report or application. This period may be extended by request of the Department at any time.
    Records of monitoring information shall include:
    a. The date, exact place, and time of sampling or measurements;
    b. The individual(s) who performed the sampling or measurement;
    c. The date(s) analyses were performed;
    d. The individual(s) who performed the analyses;
    e. The analytical techniques or methods used; and
    f. The results of such analyses.

12. Prohibition of bypassing. Except as provided in 314 CMR 5.19(13), bypassing is prohibited, and the Department may take enforcement action against a permittee for bypassing, unless the discharge is to a surface water and:
    a. The bypass was unavoidable to prevent loss of life, personal injury, or severe property damage;
    b. There were no feasible alternatives to the bypass, such as the use of auxiliary treatment facilities, retention of untreated wastes, or maintenance during normal periods of equipment downtime. This condition is not satisfied if the permittee

could have installed adequate backup equipment to prevent a bypass which occurred during normal periods of equipment downtime or preventive maintenance; and

c. The permittee submitted notice of the bypass to the Department:
   i. In the event of an anticipated bypass at least ten days in advance, if possible; or
   ii. In the event of an unanticipated bypass as soon as the permittee has knowledge of the bypass and no later than 24 hours after its first occurrence.

13. Bypass not exceeding limitations. The permittee may allow a bypass to occur which does not cause effluent limitations to be exceeded, but only if necessary for the performance of essential maintenance or to assure efficient operation of treatment facilities.

14. Permit actions. The permit may be modified, suspended, or revoked for cause. The filing of a request by the permittee for a permit modification, reissuance, or termination, or a notification of planned changes or anticipated non-compliance does not stay any permit condition.

15. Duty to reapply. If the permittee wishes to continue an activity regulated by the permit after the expiration date of the permit, the permittee must apply for and obtain a new permit. The permittee shall submit a new application at least 180 days before the expiration date of the existing permit, unless permission for a later date has been granted by the Department.

16. Property rights. The permit does not convey any property rights of any sort or any exclusive privilege.

17. Other laws. The issuance of a permit does not authorize any injury to persons or property or invasion of other private rights, nor does it relieve the permittee of its obligation to comply with any other applicable Federal, State, and local laws and regulations.

18. Oil and hazardous substance liability. Nothing in the permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties to which the permittee is or may be subject under PL 92-500, § 311, and M.G.L. c. 21E.

19. Removed substances. Solids, sludges, filter backwash, or other pollutants removed in the course of treatment or control of wastewaters shall be disposed in a manner consistent with applicable Federal and State laws and regulations including, but not limited to, the Massachusetts Clean Waters Act, M.G.L. c. 21, §§ 26 through 53 and the Clean Water Act, P.L. 92-500, as amended by P.L. 95-217 and P.L. 95-576, 33 U.S.C. 1251 *et seq*, the Massachusetts Hazardous Waste Management Act, M.G.L. c. 21C, and the federal Resource Conservation and Recovery Act, 42 U.S.C. § 6901, *et seq.*, 310 CMR 19.00 and 30.000, and other applicable regulations.

20. Reporting requirements.
   a. Monitoring reports. Monitoring results shall be reported on a Discharge Monitoring Report (DMR) at the intervals specified elsewhere in the permit. If the permittee monitors any pollutant more frequently than required by the permit, the results of this monitoring shall be included in the calculation and reporting of the data submitted in the DMR.
   b. Compliance schedules. Reports of compliance or non-compliance with, or any progress reports on, interim and final requirements contained in any compliance schedule of the permit shall be submitted no later than 14 days following each schedule date.

c. Planned changes. The permittee shall give notice to the Department as soon as possible of any planned physical alterations or additions to the permitted facility or activity which could significantly change the nature or increase the quantity of pollutants discharged. Unless and until the permit is modified, any new or increased discharge in excess of permit limits or not specifically authorized by the permit constitutes a violation.

d. Anticipated non-compliance. The permittee shall give advance notice to the Department of any planned changes in the permitted facility or activity which may result in non-compliance with permit requirements.

e. 24 hour reporting. The permittee shall report any non-compliance which may endanger health or the environment. Any information shall be provided orally within 24 hours from the time the permittee becomes aware of the circumstances. A written submission shall also be provided within five days of the time the permittee becomes aware of the circumstances. The written submission shall contain a description of the non-compliance, including exact dates and times, and if the non-compliance has not been corrected, the anticipated time it is expected to continue; and steps taken or planned to reduce, eliminate, and prevent reoccurrence of the non-compliance.

The following shall be included as information which must be reported within 24 hours:

i. Any unanticipated bypass which exceeds any effluent limitation in the permit.

ii. Violation of a maximum daily discharge limitation for any of the pollutants listed by the Department in the permit to be reported within 24 hours.

f. Other non-compliance. The permittee shall report all instances of non-compliance not reported under 314 CMR 5.19(20)(a), (b), or (e) at the time monitoring reports are submitted. The reports shall contain the information listed in 314 CMR 5.19(20)(e).

g. Toxics. All manufacturing, commercial, mining, or silvicultural dischargers must notify the Department as soon as they know or have reason to believe:

i. That any activity has occurred or will occur which would result in the discharge of any toxic pollutant listed in 314 CMR 3.16 which is not limited in the permit, if that discharge will exceed the highest of the following notification levels:

(1) 100 micrograms per liter (100 µg /l);

(2) 200 micrograms per liter (200 µg /l) for acrolein and acrylonitrile; 500 micrograms per liter (500 µg /l) for 2,4-dinitrophenol and for 2-methyl-4,6-dinitrophenol; and one milligram per liter (1 mg/l) for antimony;

(3) Five times the maximum concentration value reported for that pollutant in the permit application; or

ii. That they have begun or expect to begin to use or manufacture as an intermediate or final product or byproduct any toxic pollutant which was not reported in the permit application.

h. Indirect dischargers. All Publicly Owned Treatment Works shall provide adequate notice to the Department of the following:

i. Any new introduction of pollutants into the POTW from an indirect discharger which would be subject to PL 92-500, § 301 or 306 if it were directly discharging those pollutants; and

ii. Any substantial change in the volume or character of pollutants being introduced into the POTW by a source introducing pollutants into the POTW at the time of issuance of the permit.

iii. For purposes of 314 CMR 5.19, adequate notice shall include information on the quality and quantity of effluent introduced into the POTW, and any anticipated impact of the change on the quantity or quality of effluent to be discharged from the POTW.

i. Information. Where the permittee becomes aware that it failed to submit any relevant facts in a permit application, or submitted incorrect information in a permit application or in any report to the Department, it shall promptly submit such facts or information.

21. Signatory requirement. All applications, reports, or information submitted to the Department shall be signed and certified in accordance with 314 CMR 3.14 and 5.14.

22. Severability. The provisions of the permit are severable, and if any provision of the permit, or the application of any provision of the permit to any circumstance, is held invalid, the application of such provision to other circumstances, and the remainder of the permit, shall not be affected thereby.

23. Reopener clause. The Department reserves the right to make appropriate revisions to the permit in order to establish any appropriate effluent limitations, schedules of compliance, or other provisions which may be authorized under the Massachusetts Clean Waters Act, M.G.L. c. 21, §§ 26 through 53 or the Clean Water Act, P.L. 92-500, as amended by P.L. 95-217 and P.L. 95-576, 33 U.S.C. 1251 *et seq* in order to bring all discharges into compliance with said statutes.

24. Approval of plans and specifications for treatment works. All discharges and associated treatment works authorized herein shall be consistent with the terms and conditions of this permit and the approved plans and specifications. Any modification to the approved treatment works shall require written approval of the Department.

25. Transfer of Permits.

a. RCRA facilities. Any permit which authorizes the operation of a RCRA facility which is subject to the requirements of 314 CMR 8.07 shall be valid only for the person to whom it is issued and may not be transferred.

b. Transfers by modification. Except as provided in 314 CMR 5.19(24)(a) and (c), a permit may be transferred by the permittee to a new owner or operator only if the permit has been modified or revoked and reissued or a minor modification made to identify the new permittee.

c. Automatic transfers. As an alternative to transfers under 314 CMR 5.19(24)(b), any permit may be automatically transferred to a new permittee if:

i. The current permittee notifies the Department at least 30 days in advance of the proposed transfer date in 314 CMR 5.19(2);

ii. The notice includes a written agreement between the existing and new permittees containing a specific date for transfer of permit responsibility, coverage, and liability between them; and

iii. The Department does not notify the existing permittee and the proposed new permittee of the Department's intent to modify or revoke and reissue the permit. A modification under 314 CMR 5.19(24)(c) may also be a minor modification. If this notice is not received, the transfer is effective on the date specified in the agreement mentioned in 314 CMR 5.19(24)(c)2.

26. Permit Fees. Any permittee, other than a public entity, required to obtain a surface water or ground water discharge permit pursuant to M.G.L. c. 21, § 43 and 314 CMR 3.00 and 5.00, shall be required annually to obtain an inspection certificate from the Department, and submit the information and fee associated therewith in accordance with 314 CMR 2.12.

JBCC WASTEWATER SYSTEM - Capital Costs - Initial Improvements

November 3, 2014

RED TEXT IN MANUAL INPUT

Phase I			***Phase II*** (No Phase II facilities assumed in this project)		
Project	**Estimate**	**Costs Incurred/Comments**	**Project**	**Estimate**	**Costs Incurred/Comments**
Wastewter System Purchase Price	**$ -**	TBD			
Planning, Permitting, Legal, Admin.			**Planning, Permitting, Legal, Admin.**		
Facilities Planning & PEF	**$180,000**		Facilities Planning	$0	
Permitting & Permit Negotiation	**$70,000**		Permitting & Permit Negotiation	$0	
MassDevelopment Administration	**$50,000**		MassDevelopment Administration	$0	
PM & Conops Procurement	**$150,000**		Program Management	$0	
Legal Fees	**$30,000**		Legal Fees	$0	
Financial Consulting & Fees	**$5,000**		Financial Consulting & Fees	$0	
Planning Subtotal:	**$485,000**	Assume CY 2016	**Planning Subtotal:**	**$0**	
Design (SRF Ineligible)			**Design**		
Engineering Design	$471,800	Assume 12% of construction cost	Engineering Design	$0	
Land and other Non-eligible Costs:	$0		Land and other Non-eligible Costs:	$0	
Design Subtotal:	**$411,800**	Assume CY 2017	**Design Subtotal:**	**$0**	
Construction			**Construction**		
Construction Cost	$2,790,000	See estimate below	Construction Cost	$0	
Engineering, Inspection & Testing	$223,200	Assume 8% of construction cost	Engineering, Inspection & Testing	$0	
Construction Subtotal:	**$3,013,200**	Assume CY 2018 Begin; 2019 Complete	**Construction Subtotal:**	**$0**	
Collection System Repairs (SRF Ineligible)			**Collection System Repairs**		
Pump station repairs	$0	Cover in Asset Management line items	Pump Station & sewer systems repairs	$0	
Sewer systems repairs	$0	Cover in Asset Management line items	Effluent force main repairs	$0	
Other system repairs	$0	Cover in Asset Management line items	Other system repairs	$0	
Collection System Subtotal:	**$0**	Assume CY 2018	**Collection System Subtotal:**	**$0**	
Total Phase I JBCC/MD Capital Cost	**$3,910,000**		**Total Phase II JBCC/MD Capital Cost**	**$0**	
Total SRF Phase I JBCC/MD Capital Cost	**$3,498,200**	For SRF loan funding	**Total SRF Phase II JBCC/MD Capital Cost**	**$0**	
Regional Facilities			**Regional Facilities**		
WWTF Expansion	$0	Not applicable	WWTF base price	$0	
Connecting sewers & force mains	$0	Not applicable	Force main rehabilitation	$0	
Other facilities	$0	Not applicable	Septage facility	$0	
Total Phase I Regional Cost:	**$0**		**Total Phase II Regional Cost:**	**$0**	
Phase I Construction Estimate			**Phase II Construction Cost Estimate**		
Influent Flow EQ Pump Station	**$728,000**	WP	Base price	$0	
Sludge Feed Pumps	**$97,000**	WP	Other costs	$0	
Sludge Thickening	**$766,000**	WP	Contingency	$0	
Septage Receiving & Decant	**$1,199,000**	WP	**Total Phase II Construction Cost:**	**$0**	
3rd BNR Train	**$0**	WP			
4th Sludge Storage Tank	**$0**	WP			
Effluent Transmission & Force Main	**$0**				
Bourne Leachate Force main Connection	**$0**				
Other/Miscellaneous	**$0**				
Total Phase I Construction Cost:	**$2,790,000**				

Sheet III

DEBT SERVICE PLAN

November 3, 2014

Ownership:	MassDev
Operations:	ConOps
WWTF Design Flow:	300,000
Flows for Septage Receiving:	15,000
Flows for Effluent Disposal Only:	40,000
Flows from New Regional Partners:	0

RED TEXT IN MANUAL INPUT

Loan History	Amount	Loan Date	
SRF #1 (Phase 1)	$485,000	1/1/2016	Project Planning, Legal, Admin, etc. Loan
SRF #2 (Phase 1)	$0		Not used
SRF #3 (Phase 1)	$3,013,200	1/1/2020	WWTF JBCC Construction Loan
Phase 1 Facilities:	$3,498,200		
Town #1 Connection:	$0		N/A
Total Phase 1 Costs:	$3,498,200		
	0.00%		Regional Facilities Proportion of Total Loan

Assumptions:

Int. Rate (for res. accts):	0.50%
Inflation for Capital R&R:	0.00%
CPI-U (Boston):	0.00%
SRF Interest Rate:	2.00%
Repayment Period (yrs):	20
SRF Interim Loan Rate:	2.00%
Transaction Cost Percent:	N/A
Bridge Loan Interest Rate:	N/A

Notes:

(1) (2) Not used

(3) Based on percentages of regional facilities capacities & lengths:

User	Res. Capacity	Length	Factor	Percentage
JBCC	1	1	1	33.3%
MassDevel.	1	1	1	33.3%
Non-Military	1	1	1	33.3%
Town #1	0	0	0	0.0%
	3	3	3	100%

(4) WCR = 0.0% of Debt Service Reserve requirement

(5) 100% of interim loans for facilities planning & permitting

(6) Assume 115% of Annual Debt Service Amount

(7) Operating Reserve Requirement = Two months operating cost

Sheet IV

Annual Wastewater O&M Costs & Revenues

November 3, 2014

Septage Received (days/year)	365	Effluent Received (days/year)	365
Septage Treatment Cost ($/gal):	$0.04	Effluent Disposal Cost ($/gal)	$0.002
Septage Treatment Fee ($/gal)	$0.11	Effluent Disposal Fee ($/gal)	$0.008
		Fixed O&M Cost for @ Base Flow	$410,000
		Pump Station Asset Management	$20,000
		Collection System Asset Management	$30,000
		I/I Investigation & Repair Fund	$25,000

RED TEXT IN MANUAL INPUT

Assumptions:

Int. Rate (for res. accts):	0.50%
Inflation for Capital R&R:	0.00%
CPI-U (Boston):	0.00%
SRF Interest Rate:	2.00%
Repayment Period:	20
Transaction Cost Percent:	2.60%
Variable WWTF O&M Fee:	$0.0040

Notes:

(1) Not used
(2) From United Water
(3) Working capital reserve = 0% of debt service (not used)
(4) Debt Service Res. = 115% of Max. Ann. Debt Service Amt.
(5) MassDev. System O&M Cost: $0.00 (FY2019$)
(6) JBCC PS/Coll.System O&M: $0.00 (FY2016$)
(7) FY 2014 cost escalated to FY 2016 start-up at CPI;
(9) Contract Contingency: 15% (Not used)

Sheet V
User Rates and Revenues
November 3, 2014

RED TEXT IN MANUAL INPUT

Annual Subsidy for JBCC Military Users: See below
Inflation Rate Applied to JBCC Subsidy: 0.0%

Assumptions:

1. Billing/Collection Percentage: 100.0%
2. Discount Rate: 2.00%
3. Persons per SFR: n/a
4. Gallons per person per day: 65
5. Not used
6. Not used
7. Debt Service Coverage Ratio = Ratio of total revenue to annual outlays of cash to meet annual interest and principal payments on debt, plus sinking fund contributions.

Notes:
(1) From Sheet IV
(2) Composite for three entities
(3) First year cost = 1/2 Full Year ET Proposal

Effluent Disposal Fee ($/gal)	$0.0075
O&M Cost for @ Base Flow ($/yr)	$410,000
O&M Cost for Flow above Base Flow ($/gal)	$0.0040
Pump Station Asset Management ($/yr)	$20,000
Collection System Asset Management (&/yr)	$30,000
I/I Investigation & Repair Fund ($/yr)	$25,000
IPP/SUO Management Cost ($/yr)	$25,000
Annual Subsidy for JBCC Military Users	See below
Inflation Rate for JBCC Subsidy	0.00%
2013 JBCC O&M (W-P Estimate; JBCC Ownership) ($/gal)	$0.01139
MassDevelopment-Military Subsidy, 1st 5 years	$ 422,844
MassDevelopment- Military Subsidy, 20-yr Annual Average	$ 12,038
MassDevelopment-Non-Military Subsidy, 1st 5 years	$ 130,822
MassDevelopment- Non-Military Subsidy, 20-yr Annual Average	$ (9,104)
Net Present Value, 1st 5 Years - MassDevelopment	$ (547,730)
Net Present Value, 1st 10 Years - MassDevelopment	$ (259,892)
Net Present Value, 20 year - MassDevelopment	$ 630,230
MilitaryProjected Rate/1st 10 years	$ 10.00
Military Current Projected Rate/No Subsidy/10 Years	$ 11.85
MilitaryProjected Rate/1st 10 years/Excess Revenue to Military Ra	$ 10.00
Non-Military Projected Rate/1st 10 years	$ 11.00
Town #1 Projected Rate/1st 10 years	$ 11.00

Sheet I

Joint Base Cape Cod Business Model
Wastewater Flow Summary

November 3, 2014

RUN SCENARIO:	**2D**	
Ownership:	**MassDev**	
Operations:	**ConOps**	
WWTF Design Flow:	**450,000**	gpd
Flows for Septage Receiving:	**15,000**	gpd
Flows for Effluent Disposal Only:	**40,000**	gpd
Flows from New Regional Partners:	**148,000**	gpd

Notes:

1 Flows from 2012 CH2M Valuation Study. See tenants with zero recorded flows

2 Per capita flows from 310 CMR 15.203 (Title 5) - Not used in this assessment

3 Unaccounted for Flow = **6,204** gpd

RED TEXT IN MANUAL INPUT

Capital Cost Allocation by Reserved Capacity for WWTF

	Phase I			Phase II		
	Res. Cap.	**%**	**Cap. Share**	**Res. Cap.**	**%**	**Cap. Share**
Military	**100,000**	33.3%	$3,163,833	**0**		$0

Sheet IV

Annual Wastewater O&M Costs & Revenues

November 3, 2014

Septage Received (days/year)	365	Effluent Received (days/year)	365
Septage Treatment Cost ($/gal):	$0.04	Effluent Disposal Cost ($/gal)	$0.002
Septage Treatment Fee ($/gal)	$0.11	Effluent Disposal Fee ($/gal)	$0.008
		Fixed O&M Cost for @ Base Flow	$410,000
		Pump Station Asset Management	$20,000
		Collection System Asset Management	$30,000
		I/I Investigation & Repair Fund	$25,000

RED TEXT IN MANUAL INPUT

Assumptions:	
Int. Rate (for res. accts):	0.50%
Inflation for Capital R&R:	0.00%
CPI-U (Boston):	0.00%
SRF Interest Rate:	2.00%
Repayment Period:	20
Transaction Cost Percent:	2.60%
Variable WWTF O&M Fee:	$0.0050

Notes:

(1) Not used
(2) From United Water
(3) Working capital reserve = 0% of debt service (not used)
(4) Debt Service Res. = 115% of Max. Ann. Debt Service Amt.
(5) Mass Dev. System O&M Cost: $0.00 (FY2019$)
(6) JBCC PS/Coll.System O&M: $0.00 (FY2016$)
(7) FY 2014 cost escalated to FY 2016 start-up at CPI;
(9) Contract Contingency: 15% (Not used)

Sheet V
User Rates and Revenues
November 3, 2014

RED TEXT IN MANUAL INPUT

Annual Subsidy for JBCC Military Users: See below
Inflation Rate Applied to JBCC Subsidy: 0.0%

Assumptions:

1. Billing/Collection Percentage: 100.0%
2. Discount Rate: 2.00%
3. Persons per SFR: n/a
4. Gallons per person per day: 65
5. Not used
6. Not used
7. Debt Service Coverage Ratio = Ratio of total revenue to annual outlays of cash to meet annual interest and principal payments on debt, plus sinking fund contributions.

Notes:
(1) From Sheet IV
(2) Composite for three entities
(3) First year cost = 1/2 Full Year ET Proposal

APPENDIX C
EXCERPTS FROM THE CCC DRAFT 208 PLAN

DRAFT

208

CAPE COD AREA WIDE WATER QUALITY MANAGEMENT PLAN UPDATE

as needed, compared with a larger number of smaller facilities.

With funding from Barnstable County, the Town of Orleans supplemented its Comprehensive Wastewater Management Plan with a focused study of the options available to share wastewater facilities with the towns of Eastham and Brewster. The details of this evaluation are presented in the December 2009 Wastewater Regionalization Study (Orleans-Brewster-Eastham) (Wright-Pierce 2009). Compared with each town building its own separate wastewater facilities, two-town and three-town regional solutions may offer 6% to 9% capital cost savings and 18% to 25% O&M cost savings. Potential capital cost savings by town are:

- Brewster - $3.0 to $8.4 million
- Eastham - $2.5 to $6.9 million
- Orleans - $1.9 to $10.5 million

Two identified options involve the installation of public sewers in Brewster and Eastham, and the associated pipelines to transport the collected wastewater to the regional treatment facility. It is also possible for Orleans to remove Brewster and Eastham's shares of watershed nitrogen loads by expanding the proposed Orleans sewer system. In essence, Orleans could eliminate more Orleans septic systems to offset Brewster and Eastham nitrogen loads and have those two towns pay for that expansion. In this way, regionalization could occur without the construction of public wastewater facilities in either Brewster or Eastham.

Given the lack of required collection systems for the non-traditional technologies and approaches discussed in Chapter 3 and utilized in the watershed scenarios, traditional approaches are more likely to benefit from optimizing the factors described above. However, some non-traditional technologies, such as waste reduction toilets, may benefit from regional management arrangements for O&M. For example, a regional effort for managing urine and compost removal and/or reuse, as opposed to a town-by-town or even homeowner-by-homeowner arrangement, may present a cost savings.

Taking advantage of existing intermunicipal arrangements for water and/or wastewater is another potential cost savings method. For example, the Upper Cape Water Supply Cooperative is a regional agreement to supply water to the four Upper Cape towns of Bourne, Falmouth, Mashpee and Sandwich. Management of the Cooperative is by a Board that represents the four public water supply systems – the Town of Falmouth, Bourne Water District, Mashpee Water District and Sandwich Water District. The wells for the Cooperative are located toward the north end of Joint Base Cape Cod (JBCC), in the town of Sandwich. JBCC is also the site of a federally-owned wastewater treatment facility with the potential to support regional wastewater management needs of the Upper Cape. Potential benefits could be realized in this area given the existing intermunicipal arrangement for water supply and the existing infrastructure at JBCC. More information on the JBCC infrastructure can be found in Chapter 6.

RECCOMENDATION S4.2: Cape Cod Commission will create and assign Watershed Teams to provide technical assistance at the local level.

proportion to each town's contribution to the total nitrogen load is one of the simplest approaches.

To determine nitrogen load, the Massachusetts Estuaries Project (MEP) uses a water use approach that is applied on a parcel-by-parcel basis within a watershed. Annual water meter data is linked to parcel information and the parcel specific data is converted to septic system nitrogen discharges to the receiving watershed by adjusting for consumptive use (typically 90%) and applying a wastewater nitrogen concentration. The Commission's WatershedMVP tool is available to provide updated information on parcel specific water use to assist towns and WMAs seeking to allocate responsibility.

Not all nitrogen loads to coastal watersheds impact coastal water quality. A considerable amount of nitrogen is lost to the atmosphere and other sinks as nitrogen loads discharge to fresh surface waters before being transported to coastal waters. For example, towns that are up-gradient of ponds and streams will see that their nitrogen loads to coastal waters are significantly diminished relative to the load entering the watershed. This is referred to as natural attenuation.

Towns or waste management agencies have the option to use unattenuated nitrogen loads, which are the actual loads discharged to the ground, or attenuated nitrogen loads, which reflect the load that reaches the estuary or embayment once it's made its way through the watershed.

The stakeholder process associated with this §208 Plan Update identified a number of other factors, in addition to water use and natural attenuation, that might be considered when allocating responsibility. Stakeholders generally agreed that year round population and seasonality, as well as local growth management and land protection and acquisition plans, should be available for consideration when multiple towns are working to come to agreement on shared responsibility.

In many shared watersheds there are towns that contribute very little to the estuary or embayment. For example, Waquoit Bay is shared by Falmouth, Mashpee, and Sandwich. The attenuated nitrogen load contributions are as follows:

- Falmouth – 54%
- Mashpee – 42%
- Sandwich – 4%

The bulk of the responsibility for nitrogen management in this watershed, after attenuation, lies with Falmouth and Mashpee; however, Sandwich has a small share. In addition, part of the watershed is controlled by Joint Base Cape Cod (JBCC). See Chapter 6 for more information on JBCC, its wastewater treatment facility, and the towns within which it has land holdings.

In areas where land is controlled by a government agency that is not local the appropriate agencies need to be included in the discussion around allocating responsibility.

Towns, WMAs, or other government entities should have the option to address their portion of the responsibility by remediating nitrogen within their political boundaries or by paying for the implementation of strategies elsewhere in the watershed or receiving water body. This may be most practical for watersheds in which one of the towns has a small share of the responsibility, but could be applicable in a number of circumstances.

Another example of where this may be appropriate is in the Pleasant Bay Watershed, which is shared by the towns of Brewster, Chatham, Harwich, and Orleans. Brewster's land area is in the upper portion of the watershed and the town has little to no frontage on the estuary itself. Brewster should have the opportunity to contribute to a remediation strategy within the embayment, outside of its town boundaries, or within Pleasant Bay itself.

One option for allowing this type of cost sharing is through the use of a nutrient credit exchange program. Suggestions for this type of program are discussed further below.

Agreements allocating responsibility should include a provision relative to future amendments or changes to the TMDL approved by MassDEP and US EPA.

Towns and WMAs are encouraged to immediately begin discussions in shared watersheds to allocate responsibility for nitrogen remediation. The Commission is available to initiate and/or assist in these multi-party discussions.

The Commission will require binding agreements allocating nitrogen remediation responsibility between towns and WMAs, as appropriate, as a condition prior to issuing regulatory approvals for water quality plans and projects. This 208 Plan Update recommends that MassDEP require the same.

with conditions to develop an adaptive management plan.

Spring 2014 Town Meeting subsequently approved $50 million to construct a targeted watershed approach for a Little Pond watershed collection system and implement the pilot projects over the next five years, concluding in 2020.

A more detailed chronology of water quality planning efforts in Falmouth is available in Appendix 6G.

HARWICH

The Town of Harwich established a water quality management task force to coordinate both fresh and marine water sampling. The task force is responsible for wastewater planning, which consists of developing a CWMP and participating in the Pleasant Bay Alliance. The Harwich efforts were on hiatus while waiting for the Massachusetts Estuaries Project (MEP) to complete the technical reports for Herring River and several of the south-side embayments. These reports were received by the town in 2010–2012.

The town has since submitted an expanded ENF and anticipates participating in joint MEPA/DRI review with the Cape Cod Commission.

The CWMP includes options for regional infrastructure with the Town of Chatham for the East Harwich economic development area of town (part of the shared Pleasant Bay watershed). The town recently signed an agreement with the Town of Chatham to evaluate this option.

Harwich is also the lead town in a shared effort to improve circulation in Muddy Creek with a culvert-widening project that will likely reduce nitrogen removal requirements. Design of the culvert is close to complete and construction was scheduled to begin in May 2014. The project received two federal grants - $3.4 million of Hurricane Sandy Mitigation and Resiliency funding and a $1 million National Coastal Wetlands Conservation grant - and spring 2014 Town Meeting approved the appropriation of an additional $1.75 million.

A more detailed chronology of water quality planning efforts in Harwich is available in Appendix 6H.

MASHPEE

The Mashpee CWMP was scoped through a joint MEPA/DRI review as an ENF in 2001. In 2007, the town submitted its Needs Assessment Report entitled, “Town of Mashpee, Popponesset Bay and Waquoit Bay-East Watersheds Needs Assessment Report.” The report documents the significant level of effort that has gone into determining the nitrogen TMDLs for the two subject embayments over the course of six years. Also in 2007, the town completed a technology screening report, which was followed shortly by its draft alternative scenarios and site evaluation report in March 2008.

Mashpee has been engaged in numerous county, state, and federally funded projects, including the 2009 MassDEP Pilot Project and the 2009 Cape Cod Commission TMDL Implementation Project, which were both funded by US EPA. Through these projects, the town ran a number of scenarios through the MEP linked water quality model to evaluate TMDL compliance strategies, including an assessment of cranberry bogs and streams for potential additional natural attenuation. These projects also allowed Mashpee, together with representatives of Barnstable and Sandwich, to participate in the determination of nitrogen allocation for Popponesset Bay for each town and prepare a draft intermunicipal agreement. Mashpee received wastewater grant funds from Barnstable County to model sewer collection systems in the Popponesset watershed and technical assistance from the USGS and Commission staff to use the Sagamore Lens groundwater model to evaluate potential wastewater disposal sites.

The Needs Assessment contains a characterization of the nine operating private sewage treatment facilities, including treatment efficiency and excess capacity. This work allowed the town to focus on three potential wastewater scenarios that were developed in 2012. These options are being reviewed and will be the basis for development of their preferred alternative. The wastewater scenarios include use of the existing private plants at their planned capacity and either three or four subregional plants with consideration of shared town responsibility. Off-site disposal of effluent outside of the impaired watersheds is an important consideration for the plan’s approach. The alternatives analysis included consideration of private effluent disposal sites at New Seabury, Willowbend, and others, in addition to the town’s transfer facility site.

The town has an appointed seven-member Sewer Commission and an in-house coordinator for wastewater projects as the town proceeds with selecting a preferred alternative. Special legislation filed by the town to convert the Mashpee Water District to the Mashpee Water and Sewer District was signed by the Governor on April 18, 2014 and is pending approval by Mashpee voters. In addition to the needs and alternatives identified, the town is considering the use of the JBCC treatment facility and disposal site as long-term regional solutions.

In April 2014, the Sewer Commission met with Cape Cod Commission staff to begin the discussion around filing its

Management Plan and components of the Cape-wide Section 208 Water Quality Management Plan.

A more detailed chronology of water quality planning efforts in Orleans is available in Appendix 6J.

PROVINCETOWN

Provincetown completed a Wastewater Facility Plan in 2001. The plan dealt with the public health issues of failing septic systems and inadequate infrastructure for its commercial downtown area. The comprehensive plan was approved by state agencies through MEPA and by the Cape Cod Commission through DRI review in 2001. The wastewater facility and phase 1 and 2 areas were subsequently built and are performing well. The plan included a number of innovative aspects, including a lot-by-lot assessment of Title 5 systems, use of the Route 6 median and right-of-way for effluent disposal, combination of force mains, conventional gravity and vacuum sewers, and "checkerboard" sewer areas. The plan included three phases. The town is presently expanding sewers into the Phase 3 area and is upgrading the facility to its planned capacity. During this implementation, the town was able to use measured wastewater flow to compare to the design capacity and to negotiate the use of that excess capacity for new wastewater flow.

A more detailed chronology of water quality planning efforts in Provincetown is available in Appendix 6K.

SANDWICH

The Town of Sandwich has established a water quality committee to oversee water quality and wastewater planning efforts. The committee developed a scope of work for a Comprehensive Wastewater Management Plan and submitted the scope under the Sagamore Lens Natural Resource Damages Assessment, related to past groundwater contamination at the Textron facility at the JBCC. The town received an award of $400,000 t0 conduct its water/wastewater plan and completed a comprehensive needs assessment, as well as an interim wastewater solutions plan to accommodate economic development in the South Sandwich Village Center (often referred to as the Golden Triangle area).

The town spent several years working with a private developer on a development project that included a public-private wastewater component involving the construction of a facility that would accommodate the private project and a certain amount of general public wastewater need. That project will not be completed, but the town is again seeking a private partner to create new economic growth and to potentially participate in infrastructure development.

The town is participating in discussions at JBCC about the potential use of its existing wastewater infrastructure as a regional option for the Upper Cape towns.

A more detailed chronology of water quality planning efforts in Sandwich is available in Appendix 6L.

TRURO

The Town of Truro approved funds for a CWMP, acknowledging that protection of private-well drinking water is of paramount importance, and established a water resources oversight committee. The CWMP kicked off in 2012 with a focus on septic systems and stormwater-runoff and their impact on drinking water and embayment water quality. The planning process seeks to assemble existing data, and develop a GIS program to evaluate land and water data, historic septic-system management information and key areas for further analysis and characterization. The committee is in the process of reviewing the phase I of the draft water management plan.

A more detailed chronology of water quality planning efforts in Truro is available in Appendix 6M.

WELLFLEET

The town of Wellfleet has an established Comprehensive Wastewater Management Planning Committee that is charged with providing a comprehensive strategy for addressing wastewater treatment and disposal issues for the next 40 years and for the foreseeable build out conditions in town. Along with their consultant, they completed a draft of its CMWP Needs Assessment and Alternatives Analysis reports in June 2012. The objectives of the CWMP are to protect and enhance the Wellfleet Harbor ecosystem, promote aquaculture-based water quality management solutions, identify low-cost and sustainable remedies, develop least-cost alternatives and, only as a final resort, engage in structured solutions.

The CWMP process allowed Wellfleet to pursue and implement pilot scale ecotoilet and oyster restoration solutions. Spring 2013 Town Meeting appropriated funds to build a bathhouse at Bakers Field Beach that uses composting toilet technology to reduce the nitrogen load to Wellfleet Harbor. The oyster restoration project is a 2-acre site in Wellfleet Harbor and has a well-structured monitoring component. Water quality monitoring was conducted at the site in 2012 and 2013 and provided necessary data for the town to make informed decisions moving forward.

A more detailed chronology of water quality planning efforts in Wellfleet is available in Appendix 6N.

restriction of 0.8 MGD. The permit limits flows to the WWTF to 0.23 MGD inside the West Falmouth Harbor watershed and 0.57 MGD outside the West Falmouth Harbor watershed. On January 10, 2014 the Town received a Certificate of Adequacy from the Secretary Of Energy and Environmental Affairs to sewer the Little Pond Service Area and discharge up to 260,000 GPD at a new disposal site is being pursued ("Site 7"), north of the existing beds and outside the West Falmouth Harbor watershed. The Town is moving forward with a new effluent measuring system and optimization and improvement to the existing treatment system including the sludge thickening process at the facility.

PROVINCETOWN

The Provincetown WWTF is an advanced secondary treatment plant that is capable of treating a maximum daily flow (MDF) of 650,000 GPD, with discharge to four subsurface disposal beds at six locations along Route 6. Additional upgrades may be required to increase the capacity to allow a MDF of 750,000 in the future, and will occur when required.

AECOM is currently under a 20-year design-build-operate (DBO) agreement with the Town of Provincetown (Town) to design, permit, construct and operate its wastewater collection, treatment, and disposal systems.

The current sludge management plan includes periodic removal from the SBRs, storage for aeration and mixing, and hauling by a contractor for disposal at a facility in Cranston, RI.

JOINT BASE CAPE COD

There is also an existing WWTF at Joint Base Cape Cod. It is discussed in further detail below.

Planning Partnerships

Cape Cod is greater than the sum of its 15 towns. Because Wastewater Management Agencies will need physical domain over the lands and nutrient contributions they seek to manage, we must work with our federal and state partners to achieve water quality goals. Joint Base Cape Cod and the Cape Cod National Seashore are the largest of these state and federal land holdings, and they provide important open space and significantly reduced residential density and related wastewater discharges within their borders.

The Massachusetts Department of Transportation (MassDOT) state roadway system impacts coastal and freshwater bodies through stormwater runoff and tidal restrictions caused by state roadway bridge abutments and there is an opportunity to work cooperatively to address these issues. Federal, state and municipal governments and local land trusts also play an important role through past and future open space acquisitions that prevent new development and protect water resources. Naturally forested open space also provides a valuable nitrogen "sink" as natural systems attenuate nitrogen contributions from atmospheric deposition. Various federal and state programs are also available to assist the region as we implement water quality restoration measures.

JOINT BASE CAPE COD

RELATIONSHIP TO SURROUNDING TOWNS

At approximately 22,000 acres, Joint Base Cape Cod (JBCC), formerly known as the Massachusetts Military Reservation (MMR), is one of the largest contiguous properties in state or federal ownership on Cape Cod. JBCC is a full service military base and is home to the Massachusetts Air National Guard's (MAANG) Otis Air National Guard (ANG) Base, the U.S. Coast Guard's (USCG) Air Station Cape Cod, the Veterans Administration Cemetery, the U.S. Air Force's Cape Cod Air Force Station, and the Massachusetts Army National Guard's (MAARNG) Camp Edwards.

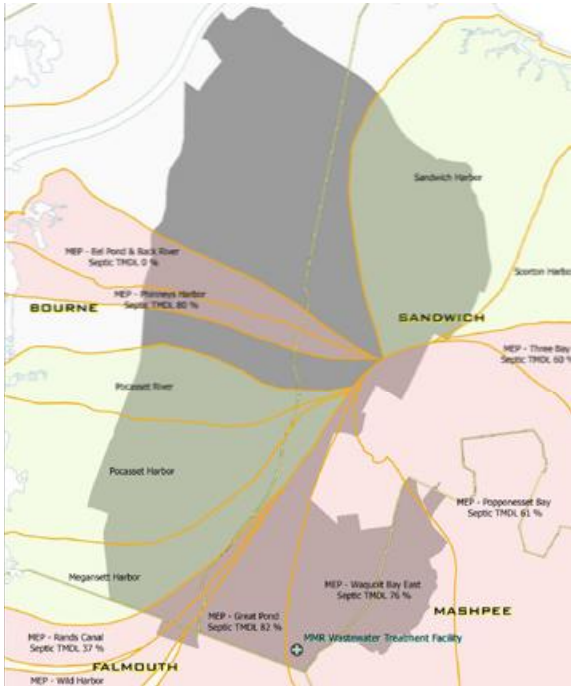
Camp Edwards, principally used for Army National Guard training, is comprised of approximately 15,000 acres in the northern portion of the base. The cantonment area, which is substantially more developed with structures, roads and other infrastructure, is comprised of approximately 7,000 acres in the southern portion of the base. JBCC includes parts of the towns of Bourne, Mashpee, and Sandwich, and abuts the town of Falmouth in Barnstable County, Massachusetts. The northern 15,000 acres of the base, also called the Upper Cape Water Supply Reserve, where the majority of the Army National Guard training occurs, was protected through a Memorandum of Agreement (MOA) and an Executive Order in 2001. The MOA was codified into law in 2002. Activities in the Reserve are subject to Environmental Performance Standards that were enacted to ensure the permanent protection of the Cape's drinking water supply and wildlife habitat in that area (Harshbarger 1998). The Environmental Management Commission ("EMC") of the JBCC consists of three members: The Commissioner of the Department of Fish and Game, the Commissioner of

the Department of Conservation and Recreation, and the Commissioner of the Department of Environmental Protection. The EMC's responsibility is to ensure the permanent protection of the drinking water supply and wildlife habitat of the Reserve and to ensure all military and other activities in those 15,000 acres are consistent with the Environmental Performance Standards. The northern 15,000 acres contains four public water supply wells as part of the Upper Cape Regional Water Supply Cooperative discussed above. The EMC is assisted by the Community Advisory Council ("CAC"), which consists of the following members: one each from Falmouth, Bourne, Sandwich and Mashpee; one family member resident of the JBCC; two representatives from the military; one from the Cape Cod Commission; one from the Wampanoag Tribe; and five other members. All members are appointed by the Governor.

STATUS OF JBCC WASTEWATER TREATMENT FACILITY

The 102nd Intelligence Wing (IW) is the host for utilities at JBCC, including the wastewater treatment plant. Massachusetts DEP issued the 102nd IW a new discharge permit early in 2004 that authorizes an average 360,000-gallon per day discharge from the Wastewater Treatment Plant (WWTP) to enable the WWTP to accept a maximum 60,000-gallon per day sewage discharge from the new Barnstable County Jail and House of Corrections just north of Connery Avenue. The location of the treatment facility is shown in Figure 6-1. The MAARNG operates two facilities in the Reserve (Camp Edwards) with individual septic systems: Range Control and the Ammunition Supply Point (ASP).

The status of the 102nd's wastewater treatment facility is based in part on information contained in Appraisal Consulting



Joint Base Cape Cod, surrounding towns, and the location of the wastewater treatment facility

Figure 6-1

Services for the Wastewater Treatment System at the MMR (Appraisal) completed in December 2012 by CH2MHill for MassDevelopment, a quasi-public state financing and development agency for the Commonwealth. Additional information was obtained from CWMPs either completed or currently in process by the four Upper Cape towns.

The JBCC wastewater system components are identified below in Table 6-1.

The wastewater management system at JBCC was designed to provide wastewater collection, onsite treatment, and onsite disposal of treated wastewater from installation facilities. As shown in Figure 6-2, wastewater is collected and conveyed by gravity and force mains to the WWTP located at the southern boundary of the base. Treated wastewater from the onsite WWTP is pumped through a 10.5 mile long effluent force main and used to recharge groundwater through rapid infiltration beds (RIBs), which are located on the northern boundary of the installation. The effluent force main and the disposal beds were constructed in 1996. The system was originally designed to allow biosolids from the WWTP to be composted and disposed of onsite as a soil amendment. Currently, wet biosolids are trucked offsite for disposal.

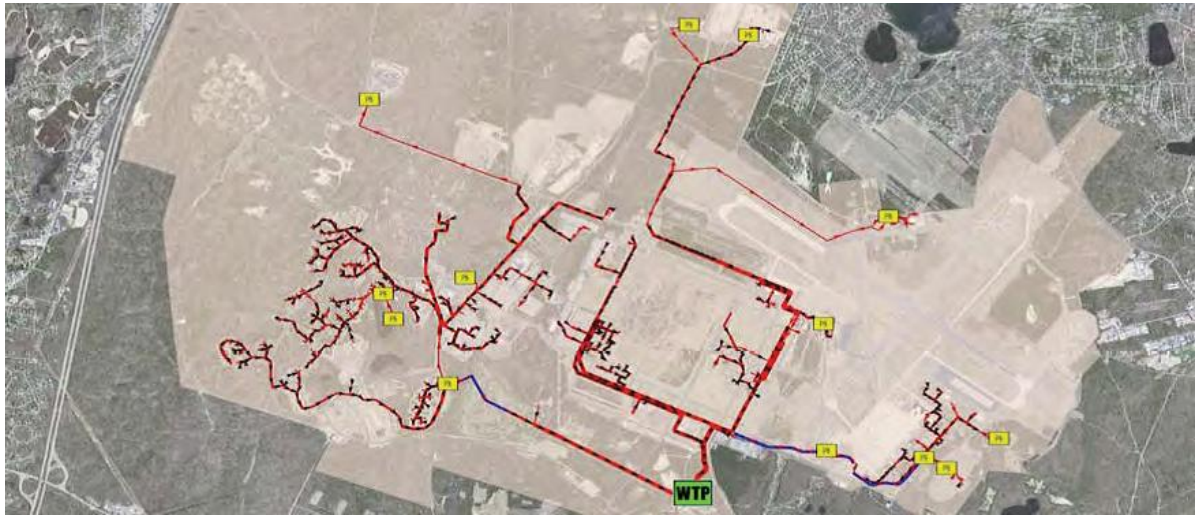
The general condition of the wastewater treatment plant was found by the CH2MHill report to be "fair" since it was upgraded in 1996 with a number of part replacements in 2002. The report also noted the condition of the collection system

COMPONENTS OF THE JBCC WASTEWATER SYSTEM

Facility Component	Size/Quantity
Collection & Conveyance Conduits:	161,000 linear feet (lf)
Manholes:	595
Pump Stations:	11
Wastewater Treatment Plant:	360,000 gpd permitted capacity
12" Treated Effluent Force Main:	55,280 lf
Rapid Infiltration Disposal Beds:	4 cells; 6 acres
Monitoring Wells:	7

Components of the JBCC Wastewater System

Table 6-1



Joint Base Cape Cod wastewater collection system (Source: CH2MHill 2012)

Figure 6-2

SUMMARY OF WASTEWATER TREATMENT AND DISPOSAL NEEDS

Entity	Near-Term Needs (gpd)	20-Year Needs (gpd)	Requirements
JBCC Users	140,040	147,300	Treatment and Disposal
Town of Falmouth	200,000	200,000	Disposal only
Bourne Landfill	40,000	80,000	Disposal only
Town of Bourne	0	1,836,000	Treatment and Disposal
Town of Sandwich	156,000	630,000	Treatment and Disposal
Town of Mashpee	158,000	658,600	Treatment and Disposal
Total: Treatment and Disposal	454,040	3,271,900	
Total: Disposal Only	240,000	280,000	

Summary of Wastewater Treatment and Disposal Needs

Table 6-2

was "cautious" since the collection system is over 50+ years old and no formal assessments have been completed. A 2001 inflow and infiltration study (I/I) indicated that I/I was a significant portion of the flow captured by the system.

The study reported that the replacement cost was $44 million, but that the replacement cost less depreciation was $16 million. The near-term and 20-year needs for JBCC users were reported as 140,000 and 147,000 gpd respectively.

The study attempted to gauge the wastewater needs of the surrounding communities. This effort made use of the best available information from the towns to reflect existing and potential wastewater needs. The total short-term and future needs were 694,000 and 3,551,900 gpd respectively for treatment and total disposal as indicated in Table 6-2 (excerpted from the study).

STATUS OF DISPOSAL SITE

Final treated effluent is pumped through a 10.5-mile ductile iron force main to four sand-lined RIBs, as shown in Figure 6-3, located on the northern boundary of the JBCC south of Route 6 (Sandwich Road).

The effluent disposal system consists of the following components:

- Piping to distribute effluent to RIBs.
- Four sand lined RIBs that cover approximately 6 acres.
- Seven groundwater monitoring wells (three pairs downgradient, one upgradient).

The soil characteristics and design parameters for the treated wastewater disposal system are described in the Hydrogeo-

logic Investigation and Design Effluent Infiltration Basins technical memorandum (CDM Smith 1993). Review of the hydrologic analysis indicates that the design capacity of the RIBs, according to Massachusetts Department of Environmental Protection (MassDEP) criteria, is substantially higher than the permitted flow to the WWTP. Based on the size of each infiltration basin and an assumed hydraulic conductivity that is typical of the Cape, the total capacity of the four RIBs is approximately 907,000 gpd. With one RIB as reserve capacity, the disposal capacity is about 672,000 gpd.

JBCC JOINT LAND USE STUDY

The Cape Cod Commission completed an update to a 2005 JBCC Joint Land Use Study (JLUS) in October, 2013. Factors prompting the Army's re-nomination of JBCC for a JLUS were changes to missions on the installation due to the 2005 Base Realignment and Closure (BRAC) round; an increase in the training population using JBCC's ranges; and concern about the compatibility of future civilian land uses surrounding JBCC.

As demonstrated in the Appraisal discussed above, the WWTP and RIBs have sufficient capacity for existing and future (20-years) JBCC military wastewater needs. Those facilities also have excess capacity to treat and dispose of wastewater generated by non-military entities. Through the JLUS process, and based on the Appraisal, the JLUS identified the potential for a military/municipal partnership and shared services through municipal use of the excess capacity of the JBCC WWTP and RIBs for wastewater and landfill leachate disposal. The JLUS states:

Given the wastewater nutrient management needs of the region to achieve TMDL [total maximum daily load] compliance and limited wastewater infrastructure on Cape Cod, existing capacity at the JBCC WWTP should be reserved for military and community needs.

Joint Base Cape Cod rapid infiltration beds (Source: CH2MHill 2012)

Figure 6-3

The Commission is developing a grant application for submission to the Office of Economic Adjustment, U.S. Department of Defense, for funds to conduct a feasibility study of the potential scenarios under which the JBCC WWTP and RIBs may be shared with the Upper Cape towns. The results of that study are anticipated in the Fall of 2014.

JBCC MILITARY AND NON-MILITARY NITROGEN CONTRIBUTIONS

As stated above, there is sufficient wastewater treatment and disposal capacity for existing and future (20-years) military needs. The JBCC controls land within 13 watersheds that are shared with the towns of Bourne, Sandwich, Falmouth and Mashpee, as shown in Figure 6-1 above. The individual municipalities are responsible for planning and implementation to prevent violations

RECOMMENDATION S6.1: Discussion and coordination with JBCC, MassDevelopment and the CCC regarding a no-net nitrogen land use policy for the base.

of the Clean Water Act. Because the JBCC controls land within watersheds that are shared with the towns, increases in the contribution of nitrogen from the JBCC within those watersheds will raise the bar for towns striving to meet TMDLs, and potentially increase the burden on municipal taxpayers.

While there is adequate treatment and disposal capacity for military uses, an unknown level of nitrogen contribution could result from non-military uses on the base. MassDevelopment has expressed an interest in promoting new development on the base with uses that do not compete with municipal economic development opportunities, and which are military-compatible. With these two caveats, this Plan supports the creation of new non-military uses that have proper wastewater treatment and disposal to ensure no net nitrogen impacts in nitrogen sensitive embayments. First, non-military uses indeed should not compete with municipal economic development, and second, that new growth facilitated by MassDevelopment should not appropriate excess capacity at the WWTP and the RIBs that would otherwise be available to serve the surrounding towns.

It is in the best interest of the military and the towns to prioritize allocation of the excess capacity of the JBCC for the needs of the neighboring towns and the military in a way that reduces the military's overhead to ensure that the base remains a strong and viable presence in our region. In the event that excess capacity is allocated to municipal uses, MassDevelopment's interest in attracting new development to JBCC can be accommodated through WWTP and RIB upgrades and possible expansion.

To ensure equity and parity between the base and the surrounding towns, this Plan proposes further discussion and coordination between JBCC leadership, MassDevelopment, and the Commission to establish a no-net-nitrogen policy for land uses within nitrogen sensitive watersheds that emanate from the base (**Recommendation S6.1**). Future agreements could also establish a protocol for allocating excess capacity at the WWTP and RIBs for municipal purposes, and establish a new, proactive communications policy between the JBCC, MassDevelopment, the Commission, and the surrounding towns.

PAST PLANS AND STUDIES REGARDING JBCC

The Commission has a webpage that provides comprehensive information on current and past plans and studies completed by the Commission regarding the JBCC, including the 2005 Joint Land Use Study and its 2013 update, as well as the MMR Master Plan Final Report, which includes background information on past environmental issues that led to subsequent planning processes. For more information, visit www.capecodcommission.org/index.php?id=306&maincatid=4.

ROLE OF THE MASSACHUSETTS DEPARTMENT OF TRANSPORTATION (MASSDOT) IN STORMWATER MANAGEMENT

79% of the Cape's land mass is in a watershed to a coastal embayment. It is therefore not surprising that miles of state roadway run through nutrient impaired watersheds on Cape Cod. To varying degree, stormwater runoff from these roadways contributes to the nutrient problems experienced on the Cape.

Through the MassDOT Impaired Waters Program (IWP), MassDOT has instituted a program to address roadway stormwater runoff draining to impaired water bodies. The program is part of the agency's compliance with its NPDES Phase II Small MS4 General Permit and commitments in an EPA enforcement

Regulatory Reform

The existing regulatory framework for wastewater is better suited for permitting traditional facilities and needs to evolve to meet the challenges of diffuse, non-point source nutrient pollution. Changes are necessary to make it easier for communities and to better respond to the problem.

Process improvements recommended in this update create a streamlined Special Review Procedure for the review of Targeted Watershed Plans jointly by MEPA and the Cape Cod Commission. **SRP (R5.5)** In shared watersheds, Targeted Nutrient Management Plans should be required; CWMPs that address only a portion of a shared watershed should no longer be permissible. Minimum performance standards and guidance will be drafted and issued pursuant to this update within 90 days of its approval. **Targeted Nutrient Management Plan (R4.4)** The MEPA process is generally the first hurdle encountered by communities planning wastewater programs requiring SRF funds.

The Cape Cod Commission Development of Regional Impact review that follows the issuance of a MEPA certificate of adequacy from the Secretary of Energy and Environmental Affairs will be reformed. A simpler and more supportive process to review Capital Developments of Regional Impacts will be developed. **CDRI (R5.4)** Local water quality management plans, and material changes to existing plans will be reviewed to ensure consistency with this update. **Consistency Review (R4.2)**

Additionally the collective responsibility of localities for nutrient loading should be updated and corresponding enforcement actions clarified. This update recommends the Massachusetts Department of Environmental Protection develop regulations outlining the process for Watershed permits for nutrient loads. **Watershed Permitting (R5.3)** This will allow communities more flexibility in designing efforts to comply with nutrient load limitations defined in the permit.

The DEP should designate those Cape Cod watersheds contributing to degraded marine estuaries and embayments as Nitrogen Sensitive Watersheds. **Designation of Nitrogen Sensitive Watersheds (R5.2)** This action brings with it certain burdens to homeowners regarding septic system upgrade requirements. These regulatory burdens should be stayed for a period of 12 months. In this timeframe, as part of the 208 update implementation process, the Cape Cod Commission, as the designated 208 regional planning entity, will convene a WMA task force to evaluate waste management agencies for watersheds in the planning area for designation by June 30, 2015. **Designation of WMA (R5.6)** MassDEP should mandate the formation of a water pollution abatement district(s) in any planning area watershed without a designated waste management agency(ies) as of June 30, 2015. **WPAD (R5.7)**

Given the importance of the federal Clean Water Act and the long-term commitment necessary to implement solutions to nutrient pollution on Cape Cod, the commonwealth should consider seeking delegated authority for the NPDES program. **NPDES delegated authority to the State (R5.1)**

Support

More direct support of local wastewater planning is warranted. This update recommends that local planning efforts consult with the Commission early in the process. The Commission will provide technical assistance by providing watershed teams to support community planning efforts. **Watershed Teams (S4.2)** These teams will assist in advising on the development of watershed scenarios with nutrient management plans consistent with this 208 update. **Hybrid Watershed Planning Approach (S4.3)** These plans will result in adaptive management implementation plans **Adaptive Management (R4.1)** qualifying for the Watershed Permit Program.

The watershed plans developed as part of the 208 Plan Update will also identify Pilot Projects and assist in identifying financial resources and direct support through the Regional Monitoring Program. **Pilot Projects (S4.1)**

Additionally, this report recognizes the importance of third-party facilitation of intra and intermunicipal disagreements and recommends the allocation of federal, state and regional resources for this purpose. **Managing Disagreement (S1.1)**

The report also suggest continued cooperation with planning partners including MassDOT **(MassDOT S6.1)** in part to develop methodologies to assess stormwater contributions from state roadways, identify opportunities to improve tidal flushing in coastal areas and use rights-of-way for water quality improvement projects. This Plan proposes further discussion and coordination with **JBCC (JBCC S6.2)** to establish a policy for land uses within nitrogen sensitive watersheds that emanate from the base.

APPENDIX D
MATERIALS SUPPORTING WATER SYSTEM ANALYSIS

Print

Acts 2000 CHAPTER 352 AN ACT ESTABLISHING THE UPPER CAPE REGIONAL WATER SUPPLY COOPERATIVE.

Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows:

SECTION 1. It is hereby declared essential for the benefit of the people of the towns of Falmouth, Bourne, Sandwich and Mashpee, in order to sustain and protect their welfare, prosperity and their living conditions, that the towns establish a supplementary water supply system, that accurate, appropriate, and self-sustaining fees, rates and charges for said supplementary water supply be established; that said supplementary systems for said municipalities be operated in a modern, efficient and financially self-sustaining manner to further their sound financial, environmental and physical condition; that conservation of water sources be encouraged; that water supplies be protected and improved; and that the towns be provided a means to insure the continued availability of water; all to the public benefit and good, and to the extent and in the manner provided herein.

SECTION 2. For the purposes specified in section 1, the Bourne water district, the town of Falmouth, the Mashpee water district and the Sandwich water district may create a water supply agency to be known as the Upper Cape Regional Water Supply Cooperative which, as created in accordance with this section, shall be a body politic and corporate and a public instrumentality, hereinafter referred to as the cooperative. The cooperative shall be created when this act has been accepted by at least the town of Falmouth and any other water district enumerated above, or by any two water districts enumerated above. Such acceptance shall be, in the case of the town of Falmouth, by a vote taken in accordance with section 4 of chapter 4 of the General Laws and in the case of the Mashpee water district, the Sandwich water district or the Bourne water district, by a vote of its inhabitants at an annual or special ballot election. Upon creation, the cooperative shall have, any general or special law notwithstanding, as hereinafter provided and in accordance with this act, the power and authority to extract groundwater supplies as the board of managers may determine is appropriate, and to locate wells, determine rates of extraction, construct, operate, and maintain a public water supply and appurtenant water distribution works within the geographical area described as follows:

That land located in the towns of Sandwich, Bourne, and Mashpee, Falmouth, owned by the commonwealth and known as the Massachusetts Military Reservation; provided, however, that the cooperative shall take no action which will interfere with the lawful operations of: (*i*) the Department of the Army pursuant to a lease between the commonwealth and the United States of America

dated July 1, 1976; (*ii*) the Department of the Air Force pursuant to a lease dated July 1, 1974 between the commonwealth and the United States of America, as superseded by lease contract No. DACA51-5-75-293 between the United States of America and the commonwealth, and as modified by a supplemental agreement between the commonwealth and the United States of America dated July 1, 1976, lease contract No. DACA51-5-75-293, Modification No. 3, and Supplemental Agreement No. 4 dated April 11, 1995; (*iii*) the Department of Transportation, U.S. Coast Guard, pursuant to a lease between the commonwealth and the United States of America dated July 1, 1976; (*iv*) the Massachusetts army national guard, pursuant to a license from the secretary of the Army to the commonwealth dated July 2, 1976; or (*v*) the Massachusetts air national guard pursuant to a license from the secretary of the Air Force to the commonwealth dated November 30, 1983.

If any municipal entity, once having accepted this act in accordance with the provisions of this section, desires to withdraw from the cooperative, it may do so with 24 months prior written notice to the board of managers, and in the same manner provided for acceptance of this act; provided, however, that such withdrawing municipal entity shall be obligated to pay its pro rata share on the municipal entity's obligations for the fiscal year in which it withdraws, together with its pro rata share on all bonds or notes which have been approved prior to the date upon which such municipal entity gives notice of its intention to withdraw from the cooperative. In the event that any municipal entity which has not accepted this act within one year of its effective date, desires thereafter to do so, it may do so in accordance with this section, provided that the board of managers, in consultation with the board of selectmen or water commissioners of such municipal entity, shall first fix and determine an equitable share of capital expenses incurred to that date by the cooperative, which sums shall be payable upon such terms as may be agreed between the board of managers and such municipal entity. In the event that the board of managers and the municipal entity desiring to join the cooperative are unable to agree on such equitable share, the matter shall be submitted to arbitration by a panel consisting of one member of the board of managers, or its designee, one member of the board of selectmen or water commissioners for the municipal entity or their designee, and a third party selected by the first two members of the panel. Said third party shall be a disinterested person without any business interest or residence in any of the municipal entities. Said arbitration panel shall hear the arguments and information submitted by the board of managers and the municipal entity desirous of joining the cooperative. After consideration of the respective positions of the board of managers and the municipal entity desirous of joining the cooperative on what constitutes an equitable share of capital expenses incurred to that date by the cooperative, the arbitration panel shall determine the amount of such equitable share and, if the parties are unable to agree, the terms of payment therefore, and such determination shall be final and conclusive upon the board of managers and the municipal entity desirous of joining the cooperative. The availability of water from the cooperative shall not be considered an alternative to the development of municipal supplies of water by any of the municipal entities for the purposes of section 62B of chapter 30 of the General Laws, irrespective of whether or not the municipal entity seeking approval of such municipal water supplies has joined the cooperative or not, nor shall the

availability of such water form any basis for the decision of an agency of the commonwealth to make a finding pursuant to section 61 of said chapter 30.

SECTION 3. The management and control of all property acquired by, and the exercise of all powers, privileges and duties conferred upon the cooperative pursuant to the provisions of this act shall be vested in and exercised by a board of managers, which shall consist of two members appointed by the board of water commissioners, in the case of any water district which has accepted this act, and by the board of selectmen, in the case of any town which has accepted this act. The cooperative shall be deemed a governmental body pursuant to chapter 30B of the General Laws. Notwithstanding any general or special law to the contrary, the administrators of the cooperative who are procurement officers for said cooperative shall participate in the Massachusetts public purchasing official certification program conducted by the office of the inspector general in order to earn a Massachusetts public purchasing official certificate. Of the two representatives of each town or district which has accepted this act, one member shall serve for a term of two years, and the other shall serve for a term of three years. Members of the board of managers shall be paid $1,000 annually, and the chairman shall be paid $1,500 annually. Members may be removed for cause by their appointing authority. Members of the board of managers, together with its agents, employees, and professional staff shall be indemnified against personal liability by the cooperative. The cooperative shall be deemed a public employer pursuant to chapter 258 of the General Laws. The cooperative acting through its initial board of managers shall promptly adopt by-laws describing by whom and how meetings of the board may be called, notified and conducted; establish rules and regulations for the management of its affairs not inconsistent with this act or any other provision of law; shall appoint for such term as it may determine, a corporate treasurer of the cooperative, and such other officers and employees not specifically provided for in this act as it may deem necessary and proper, and shall fix their compensation. The treasurer shall not be a member of the board of managers, and shall give bond to the cooperative in such an amount as may be approved by said board with a surety company authorized to transact business in the commonwealth as a surety. The cooperative may contract with any of the municipal entities for treasurer services upon terms mutually agreeable to the cooperative and the municipal entity. A majority of appointed managers shall constitute a quorum of the board of managers. Vacancies occurring in the membership of the board of managers from any cause may be filled for the remainder of the unexpired term by the appointing authority. No vacancy occurring in the membership of the board of managers shall disqualify the board of managers from taking any action authorized by this act.

The board of managers shall annually prepare and provide to the board of selectmen of the town of Falmouth and the water commissioners of the towns of Bourne, Mashpee, and Sandwich that have accepted this act, and to each user of water of the cooperative who requests the same, a written report of the condition of the system, the actions of the board of managers, and receipts and expenditures of the cooperative for the preceding fiscal year.

SECTION 4. The cooperative, acting by and through its board of managers, shall have all the rights and powers necessary or convenient to carry out and effectuate the purposes of this act including, but without limiting the generality of the foregoing, the following rights and powers:

(*a*) to adopt the by-laws for the regulation of its affairs and the conduct of its business, to promulgate rules, regulations and procedures in connection with the performance of its functions and duties, and to fix, enforce, and collect penalties for the violations thereof;

(*b*) to adopt an official seal and alter the same at its pleasure;

(*c*) to maintain an office at such place or places as it may determine;

(*d*) to apply for, receive, accept, administer, expend, and comply with the conditions, obligations and requirements respecting any grant, gift, loan, including without limitation any grant, gift or loan from agencies of local, state, and federal governments, donation or appropriation of any property or money in aid of the purposes of the cooperative, and to accept contributions of money, property, labor, or other things of value;

(*e*) to acquire by purchase, lease, lease purchase, sale and lease back, gift, or devise, or to obtain options for the acquisition of, any property, real or personal, easements, water, or water rights, or any interest therein, in the exercise of its powers and the performance of its duties;

(*f*) to sell, lease, mortgage, exchange, transfer or otherwise dispose of, or grant options for any such purposes with respect to, any water, water rights, and any other property, real or personal, tangible or intangible, or any interest therein;

(*g*) to enter onto any land within the geographical boundaries of the cooperative to make surveys, borings, soundings and examinations thereof, provided that the cooperative shall insofar as possible restore the land to the same condition as prior to the making of such surveys, borings, soundings, and examinations;

(*h*) to construct, improve, extend, enlarge, maintain, and repair the water works system located within the geographical jurisdiction of the cooperative;

(*i*) to make contracts of every name and nature, and to execute and deliver all instruments necessary or convenient for carrying out any of its purposes;

(*j*) to fix, revise, charge, collect and abate fees, rates, rents, delinquency charges and other charges for water and other services, facilities and commodities furnished or supplied by it;

(*k*) to sue and be sued and to prosecute and defend actions relating to its properties and affairs, provided that only property of the cooperative other than revenues pledged to the payment of bonds

or notes shall be subject to attachment or levied upon execution or otherwise;

(*l*) to from time to time sell such of the property of the cooperative as shall, in the opinion of its board of managers, be no longer useful in the conduct of the affairs of the cooperative;

(*m*) to employ personnel and to engage architectural, engineering, accounting, management, legal, financial, and environmental consulting and other professional services;

(*n*) to establish specific construction standards and specifications for the water distribution supply system;

(*o*) to charge a systems development charge to customers who are not municipal entities seeking to connect into the water supply system; in such amount as the board of managers may determine; provided, however, that no systems development charge shall be made to Otis air national guard Base, 102FIW/DEEV, Building 971, Otis air national guard Base, MA 02542-5028 any successor registrant for any connection to the water supply system which provides an amount of water equal to or less than the amount of 197.10 MGY Total Annual Volume withdrawal for which the Otis air national guard Base registered with the department of environmental protection pursuant to registration no. 4-22-225.02, dated May 28, 1999, but the said Otis air national guard Base, or any successor registrant may be charged a systems development charge for any supply of water over or above the volume set forth in said registration; and

(*p*) to do all things necessary, convenient or desirable for carrying out the purposes of this act for the purposes expressly granted or necessarily implied in this act.

SECTION 5. Fees, rates, rents, assessments, and other charges for water or other services, facilities, and commodities furnished or supplied by the cooperative shall be fixed and adjusted by the board of managers so as to provide funds at least sufficient in each fiscal year, together with other revenues and funds of the cooperative, if any, available therefore, to pay the full cost of operation of the cooperative for that fiscal year, including all current expenses; all debt service on bonds or notes of the cooperative; all costs of maintenance, repair and replacement, including the establishment of reasonable sinking funds, overlay funds, stabilization funds, replacement reserves, and other similar funds in accordance with generally accepted accounting principles, as determined by the board of managers to be necessary or desirable to be funded as current expenses; and all other amounts which the cooperative may be obligated to pay or provide for by law or by contract. Notwithstanding any general or special law to the contrary, the board of managers may establish rates, including differential rates, rents, assessments, fees and other charges authorized by this act which may vary depending on whether the customer is a municipal entity as referred to in section 2, or is a customer which is not a municipal entity.

SECTION 6. The cooperative, for the purpose of paying expenses of maintenance and operation not covered by charges for water may, any other general or special law notwithstanding, and in

accordance with this section, from time to time assess sums against the municipal entities that have accepted this act in accordance with section 2. If the board of managers of the cooperative desires to make such assessments, the board of managers shall determine what sum, in the aggregate, is necessary to pay for expenses of the cooperative not covered by fees charged in accordance with section 5, and shall apportion such amount in accordance with the proportional annual use by each municipal entity of the total amount of water being supplied by the cooperative. Upon determining such amounts, the board of managers shall certify, to the board of selectmen in the town of Falmouth, and to the board of water commissioners of the Bourne water district, Sandwich water district or Mashpee water district who shall have accepted the provisions of this act in accordance with section 2, that the board of managers have authorized an assessment against such municipal entities, and the amount to be assessed against each municipal entity therefore. The board of selectmen or the board of water commissioners, as the case may be, of each municipal entity, shall cause to be placed on the warrant for the next available special or annual town or district meeting, an article in the form specified by the board of managers, seeking authorization from the town or district meeting to raise and appropriate such amounts, for payment over to the cooperative. Upon approval by the town or district meeting of two-thirds of such municipal entities, notwithstanding any other general or special law to the contrary, all municipal entities that have been assessed by the board of managers in accordance with this section, shall raise and appropriate, and pay over to the cooperative, such sums as have been assessed. Any sums assessed by the cooperative and raised and appropriated by a municipal entity in accordance with this section shall not be subject to sections 20A, 20B and 21C of chapter 59 of the General Laws.

SECTION 7. The cooperative, for the purpose of paying necessary expenses and liabilities incurred under this act, other than expenses of maintenance and operation, may, any other general or special law notwithstanding, and in accordance with this section, from time to time borrow such additional sums as may be necessary, not exceeding, in the aggregate $50,000,000 and issue bonds or notes therefore which shall bear on their face the words Upper Cape Regional Water Supply Cooperative Loan Act of 2000 and such other distinguishing designation as may be determined by the board of managers, and each authorized issue shall constitute a separate loan and such loans shall be payable in not more than 40 years from their dates, notwithstanding any other provision of law. The cooperative may borrow from time to time such funds as may be necessary for the purposes of this act in anticipation of revenue without the necessity of complying with this section. Indebtedness incurred under this act shall, except as otherwise provided herein, be subject to chapter 44 of the General Laws.

Prior to the issuance of such bonds or notes, other than borrowings in anticipation of revenue, the board of managers shall apportion the cost of repayment of each bond or note, which cost shall be apportioned to each municipal entity which has accepted this act pursuant to section 2 in accordance with the proportional annual use by each such municipal entity of the total amount of water supplied by the cooperative. Upon determining such amounts, the board of managers shall

certify, to the board of selectmen in the town of Falmouth, and the board of water commissioners of the Bourne water district, Sandwich water district or Mashpee water district, who shall have accepted this act in accordance with section 2, that the board of managers have authorized the issuance of such bonds or notes, and the amount to be assessed against each municipal agency therefore. The board of selectmen or board of water commissioners, as the case may be, of each municipal entity, shall cause to be placed in the warrant for the next available special or annual town or district meeting, an article in the form specified by the board of managers, seeking authorization from the town or district meeting for the cooperative to issue such bonds or notes, and the amount to be assessed therefore against each municipal agency. Upon approval by the town or district meeting of two-thirds of such municipal entities, the cooperative may issue such bonds or notes as have been approved. Such bonds or notes shall be issued upon the full faith and credit of the cooperative, and of all municipal entities who have accepted this act in accordance with section 2, notwithstanding any other provision of law. If two-thirds of the municipal entities which have accepted this act in accordance with section 2 shall approve the issuance of bonds or notes as set forth herein, all municipal entities which have accepted this act in accordance with section 2 shall, notwithstanding their refusal to approve such bonds or notes at an annual or special district or town meeting, as the case may be, be obligated to pay all sums certified by the cooperative pursuant to this section. The indebtedness on bonds or notes issued by the cooperative and the municipal entities pursuant to this act shall not be subject to section 10 of chapter 44, and sums assessed by the cooperative to repay such bonds or notes shall not be subject to sections 20A, 20B and 21C of chapter 59 of the General Laws.

The fiscal year of the cooperative shall commence July 1 and end June 30, or as otherwise provided in the by-laws of the cooperative.

SECTION 8. Whoever intentionally corrupts, pollutes or diverts any water obtained or supplied under this act, or intentionally injures any reservoir, well, standpipe, aqueduct, pipe or other property owned or used by the cooperative for any of the purposes of this act, or tampers with any metering device owned or utilized by the cooperative, shall forfeit and pay to the cooperative three times the amount of damages assessed therefore, to be recovered in an action of tort, together with reasonable attorney's and engineering costs and expenses incurred by the cooperative in the investigation, assessment, and prosecution of such action. Whoever is convicted of any of the above acts shall be punished by a fine of not more than $10,000 or by imprisonment for not more than one year, or both.

SECTION 9. In the event that the board of managers desires to terminate the cooperative and dispose of its assets, a majority of the board of managers then existing shall first vote to do so, and give notice of such vote, in writing, to the board of selectmen, and board of water commissioners, of any municipal entity which has accepted this act in accordance with section 2. Each municipal entity shall thereafter provide, at its next regular or special election, a ballot vote which shall contain the question "Shall the Upper Cape Regional Water Supply Cooperative be dissolved, and its assets

deposed of in accordance with the vote of its board of managers?". If a majority of municipal entities which have accepted this act vote in the affirmative, the cooperative shall be dissolved, but not otherwise. In the event of such affirmative vote, the board of managers shall be empowered to dispose of the assets of the cooperative in accordance with the General Laws.

SECTION 10. If the cooperative authorized by section 2 is not created in the manner described in said section 2 within ten years from the effective date of this act, then this act shall be without further legal effect.

SECTION 11. This act shall take effect upon its passage.

Approved December 21, 2000.

RENEWAL REGISTRATION STATEMENT FOR VERIFIED WATER WITHDRAWAL

The Massachusetts Department of Environmental Protection ("the Department") hereby accepts the Registration Renewal Request filed by the following Registrant pursuant to 310 CMR 36.10 for the water withdrawal described below. The Registrant is hereby authorized to withdraw up to the registered volume of water from the registered withdrawal point(s) until the expiration date, as set forth below, in compliance with M.G.L. c. 21G and 310 CMR 36.00, subject to the Registration Conditions set forth below.

GENERAL INFORMATION

Registration Number: 42222502 River Basin: CAPE COD

Registrant: OTIS ANG BASE
197 GRANVILLE AVE
OTIS ANG BASE, MA 02542

Number of registered withdrawal points: 2
Groundwater: 2 Surface water: 0

SourceID	Type	Source Name
4096001-01G	GW	WELL J
	GW	WELL G

Use: Public Water Supply

Average Volume per Day (MGD): 0.54 Total Annual Volume (MGY): 197.10

Days of Operation: 365

Effective Date: January 1, 2008 Expiration Date: December 31, 2017

can implement the MassDEP Model Conservation Plan for UAW at any time and then be considered to have met the functional equivalent of the performance standard.

The MassDEP Model Conservation Plan has not been completed at this time. The Department is committed to working with interested stakeholders, particularly the Massachusetts Water Works Association, to develop model conservation plan that provides a menu of best management practices for registrants to refer to and to use as they develop their own compliance plan. We anticipate developing a water management toolbox over the next several months that will meet the needs of suppliers and meet the Department's commitment to protect water resources while we balance human and environmental needs.

The Department plans to engage interested parties in discussions on rate structures, the experiences of water suppliers and other utilities incorporating rates into their conservation programs, and the impact of conservation on revenues. The Department anticipates incorporating the findings of our discussions into the water management toolbox. We look forward to your input on these matters.

Seasonal Demand Management

PWSs will be required to develop a Seasonal Demand Management Plan to reduce nonessential outdoor water use from May 1st to September 30th. The Department will be working in the coming months with the Massachusetts Water Works Association and the Water Management Advisory Committee to develop an outline of the minimum elements that will be required in a Seasonal Demand Management Plan. The Department will forward the Seasonal Demand Management Plan outline to registrants by May 1, 2008. Registrants will be required to forward a draft of their proposed Seasonal Demand Management Plan to the Department for its review and approval by August 1, 2008. The Department anticipates that many PWSs will already have developed and implemented seasonal water use restrictions that meet the minimum requirements in this Registration Statement. Suppliers can always implement stricter restrictions than those required by the Department. For more information on the Massachusetts Drought Task Force and drought declarations, please see http://www.mass.gov/dcr/waterSupply/rainfall/drought.htm

In addition, the Department has included more information that was submitted by Registrants in 1988 and updated the documents to include changes that have occurred since 1988, including:

- A detailed list of ground and surface water sources, including the PWS source ID, for all registered withdrawal points. The Department has added this information to reflect the withdrawal points registered in 1988; and
- Replacement wells and/or satellite wells, if applicable.

Finally, the Department has included the following administrative language:

- Enforcement language that reserves the Department's rights in any case where there is an ongoing proceeding, or may be a future proceeding; and
- Appeal language that explains how the registrant can seek review of the Registration Conditions in the Renewal Registration Statement in an adjudicatory proceeding.

Many registered PWSs also hold Water Management Act permits. If the Registrant holds a Water Management Act permit, then the conditions in the permit, including all applicable deadlines, shall supersede the corresponding conditions in this Registration Statement.

Massachusetts Water Management Act Registration Statement
Content and Conditions for 2008-2017

The enclosed renewed Water Management Act Registration Statement authorizes continued withdrawals from January 1, 2008 through December 31, 2017. This Registration Statement reflects your documented water withdrawals from January 1, 1981 through December 31, 1985, and the source locations from which this water was withdrawn. While the initial Water Management Registration Statements had to be filed with the Massachusetts Department of Environmental Protection (the Department) by January 1, 1988, existing registrants have the opportunity to renew the Statements every ten years thereafter. Earlier this year you requested that your Registration be renewed, and the attached Registration Statement confirms your authorized registered withdrawal volumes and sources.

As noted in the Department's August 2007 Registration Renewal Request, the Department has evaluated including water conservation measures in registrations that are consistent with the State Water Conservation Standards approved by the Water Resources Commission (WRC) in July 2006. To better achieve a balance between competing water withdrawals and uses mandated by the Act, to protect the natural environment, and to provide continued and sustainable economic growth in the Commonwealth, the Department is including water conservation measures in Public Water Supply (PWS) Registration Statements pursuant to M.G.L. c. 21G, §§(5) and (6), that include:

- a requirement that PWSs meet the WRC's performance standards of 65 residential gallons per capita day water use (RGPCD) and 10% unaccounted for water loss (UAW) by December 31, 2017
  - because of the difficulty accurately calculating the RGPCD value in seasonal communities, PWSs on the Cape and Islands are not required to meet the 65 RGPCD standard;
- a requirement that those not meeting specific performance milestones must develop and implement a compliance plan in advance of December 31, 2017;
- a prohibition on the use of decreasing block rates in establishing service charges (M.G.L. c.40, § 39L);
- a requirement that PWSs begin implementing by May 1, 2009 a Seasonal Demand Management Plan that, at a minimum, restricts nonessential outdoor water use between May 1st and September 30th when the Massachusetts Drought Management Task Force declares a drought level of "Advisory", "Watch", "Warning" or "Emergency" for the region in which the PWSs withdrawals are located. Restrictions on outdoor water use shall remain in force until the drought level is declared to be "Normal" by the Drought Management Task Force.

<u>UAW Performance Standard</u>
The Registration Statements include steps that PWSs will need to take if they are having difficulty meeting the performance standard. The Registration Statement outlines a timetable for PWSs to develop and implement their own plan for bringing their system into compliance with the performance standard. Alternatively, a PWS

REGISTRATION CONDITIONS

The Registrant shall comply at all times with M.G.L. c. 21G, 310 CMR 36.00 and all other applicable state and federal statutes and regulations.[1] In addition, the Registrant shall comply with the following conditions, provided, however, that if the Registrant holds a currently valid Water Management Act permit, then the conditions in the permit, including all applicable deadlines, shall supersede the corresponding conditions in this Renewal Registration Statement.

Metering:
The Registrant shall install and maintain source meter(s) for each withdrawal point(s).
The Registrant shall calibrate all source meter(s) annually.

Records:
The Registrant shall maintain withdrawal records in sufficient detail to timely provide the information necessary to accurately complete each Annual Statistical Report (ASR) it files with the Department.

Performance Standard for Unaccounted-for Water:
The Registrant shall comply with the 10 % Unaccounted-for Water (UAW) performance standard included in the Massachusetts Water Resources Commission's State Water Conservation Standards (July 2006) as soon as feasible but no later than **December 31, 2017.** The Registrant shall annually document its actual UAW in the ASRs it files with the Department, commencing with its ASR for calendar year 2008. The Registrant's ASRs shall document that it is making demonstrable progress towards meeting the UAW performance standard. Commencing with its ASR for calendar year 2017, and for each year thereafter, the Registrant shall document that it is in full compliance with the performance standard for UAW.

If the Registrant's ASR for calendar year 2009 indicates that the Registrant is exceeding 15% UAW, then the Registrant shall develop and implement an annual compliance plan designed to meet the 10% UAW performance standard by December 31, 2017. The Department will make the MassDEP Model Conservation Plan, including a menu of best management practices (BMPs), available to the Registrant for adoption or consideration in developing its own compliance plan. The Registrant shall submit a copy of its first compliance plan to the Department by December 31, 2010, and begin implementation upon submittal.

If the Registrant's ASR for calendar year 2012 indicates that the Registrant is exceeding 10% UAW, then the Registrant shall develop and implement an annual compliance plan designed to meet the 10% UAW performance standard by December 31, 2017, unless it has done so already. The Registrant shall submit a copy of its first compliance plan to the Department by December 31, 2013, and begin implementation upon submittal.

The Department reserves the right to commence enforcement against the Registrant if it is not making demonstrable progress towards meeting the performance standard, or if it has not developed and implemented an annual compliance plan that is reasonably designed to meet the 10% UAW performance standard by December 31, 2017. In exercising its enforcement discretion, the Department will consider the Registrant's past efforts to come into compliance with the requirement.

Note: Those registrants with UAW above 10% may choose to adopt the MassDEP Model Conservation Plan at any time before December 31, 2017. Those registrants that have adopted the MassDEP Model

[1] Regulations may change from time-to-time. The Registrant is responsible for complying with the most current version of the applicable regulations, unless the regulations expressly provide otherwise.

Conservation Plan, and have made appropriate arrangements to finance, implement and enforce its provisions, will not be subject to enforcement for exceeding the 10% UAW performance standard provided that they are continuing to make reasonable efforts to implement and enforce their compliance plan. Those registrants that have not adopted the MassDEP Model Conservation Plan prior to December 31, 2017, and/or that are not making reasonable efforts to finance, implement and enforce their compliance plan provisions, may be subject to enforcement for exceeding the 10% UAW performance standard and may be required to adopt the MassDEP Model Conservation Plan, if they have already not done so.

Seasonal Demand Management – May 1 through September 30:
The Registrant shall submit a Seasonal Demand Management Plan by August 1, 2008 for the Department's review and approval. The Plan must begin by May 1, 2009, and must restrict at a minimum, nonessential outdoor water use from May 1 through September 30th when the Massachusetts Drought Management Task Force declares a Drought Advisory, Drought Watch, Drought Warning or Drought Emergency for the region where the Registrant's withdrawals are located. Restrictions on outdoor water use shall remain in place until the drought level is returned to "Normal."

> Nonessential Water Use: As used herein, "nonessential outdoor water use" means uses that are not required: (a) for health or safety reasons; (b) by regulation; (c) for the production of food and fiber; (d) for the maintenance of livestock; or (e) to meet the core functions of a business.
>
> Examples of nonessential outdoor water uses include: the irrigation of lawns or landscaping, except by means of a hand-held hose outside the hours of 9:00 a.m. to 5:00 p.m.; washing vehicles other than by means of a commercial car wash or except as necessary for operator safety; and washing of exterior building surfaces, parking lots, driveways and/or sidewalks, except as necessary to apply paint, preservatives, stucco, pavement, cement, or the like.
>
> Examples of acceptable outdoor water uses outside the hours of 9:00 a.m. to 5:00 p.m. include: irrigation to establish a new lawn during the months of May and September; irrigation for the production of food and fiber or the maintenance of livestock; irrigation by plant nurseries as necessary to maintain stock; irrigation by golf courses as necessary to maintain greens and tees, and limited fairway watering; and irrigation of public parks and recreational fields.

Nothing in this Registration Statement shall be construed to prohibit or prevent the Registrant from implementing any water use restrictions stricter than those contained herein.

Note: 310 CMR 22.15(8) requires that all public water systems establishing mandatory restrictions on water use notify the Department in writing within 14 days of the effective date of such restrictions. Notice must include a description of the regulations, bylaws or ordinances imposing the restriction. Registrants may also be required to document implementation and enforcement of the restrictions in their ASRs.

For the most up-to-date information on the drought status in your region, the Registrant should monitor the Department's website at www.mass.gov/dep and MassDCR's website at http://www.mass.gov/dcr/waterSupply/rainfall/drought.htm.

SERVICE CHARGES
The Registrant shall not charge for water services on a descending unit rate basis (i.e. decreasing block rates). Descending unit rate basis that charge lower unit prices as water use increases during the billing period are prohibited by M.G.L. c. 40, § 39L.

REPORTING

The Registrant shall file an annual statement of withdrawal, as required by 310 CMR 36.11, for each year that this registration is in force, on forms provided and by the deadline specified by the Department. At the request of the Department, the Registrant may be required to report withdrawal volumes monthly or daily in accordance with 310 CMR 36.08.

EFFECT ON ANY PENDING AND FUTURE ACTIONS

The withdrawal registration program is intended to provide a procedure and deadline for persons making existing withdrawals above the threshold quantity to file a registration statement with the Department for their existing withdrawals to enable the Department to document baseline water use to manage the surface and groundwater of the Commonwealth. Except as expressly provided herein, this Renewal Registration Statement shall not be construed or operate as barring, diminishing, adjudicating or in any way affecting any legal or equitable right of the Department with respect to any pending administrative or judicial action, or any such future action, including without limitation any pending enforcement action or permit appeal, or any legal or equitable right of the Department to pursue any claim, action, suit, cause of action, or demand that the Department may have with respect to any matter covered by this Renewal Registration Statement.

REGISTRATION RENEWAL

This Registration Statement expires on January 1, 2018, unless the Registrant files a registration renewal request with the Department prior to that date in accordance with 310 CMR 36.10. Failure to file a registration renewal request by the expiration date shall result in the loss of the Registrant's right to withdraw the water volumes authorized by this Renewal Registration Statement until a permit for such withdrawal has been obtained from the Department.

REGISTRATION TRANSFER

The transfer of Registration Statements is governed by 310 CMR 36.09. Except as provided in 310 CMR 36.09(2), this Renewal Registration Statement may be transferred, in whole or in part, by the Registrant to another person if (1) the Department is notified of the proposed transfer at least 30 days in advance of the proposed transfer date, (2) the notice includes a written agreement between the parties to the transfer, (3) the notice provides the date that the proposed transfer is to take place, and (4) the notice describes the registration to be transferred. A transfer request must be accompanied by the applicable fee established in 310 CMR 4.00. This Renewal Registration Statement shall be surrendered to the Department upon transfer of any withdrawal authorized by this document.

APPEALS

The Registrant may request an adjudicatory hearing on this Renewal Registration Statement by timely filing a Notice of Claim for an Adjudicatory Appeal ("Notice of Claim") in accordance with M.G.L. c. 30A, § 10 and 310 C.M.R. 1.00 within twenty-one (21) days of its receipt of this Renewal Registration Statement. The Notice of Claim shall state specifically, clearly and concisely the facts that are grounds for the appeal, the relief sought, and any additional information required by applicable law or regulation. A copy of this Renewal Registration Statement shall be included with a Notice of Claim. The Notice of Claim and supporting documentation must be sent to:

Case Administrator
Office of Appeals and Dispute Resolution
Department of Environmental Protection
One Winter Street, Second Floor
Boston, MA 02108

In addition, a valid check made payable to the Commonwealth of Massachusetts in the amount of $100 for the appeal filing fee, if required, must be mailed to:

Commonwealth of Massachusetts Lock Box
Department of Environmental Protection
P.O. Box 4062
Boston, MA 02211

The Notice of Claim may be dismissed if the filing fee is not paid, unless the appellant is exempt or granted a waiver. The filing fee is not required if the appellant is a city, town (or municipal agency), county, district of the Commonwealth of Massachusetts, or a municipal housing authority. The Department may waive the adjudicatory filing fee for a person who shows that paying the fee will create an undue financial hardship. A person seeking a waiver must file, along with the hearing request, an affidavit setting forth the facts believed to support the claim of undue financial hardship.

SECTION 1

PRELIMINARY STRATEGY

1.1 INTRODUCTION

The Towns of Bourne, Falmouth, Mashpee and Sandwich were awarded a Community Compact Cabinet's Efficiency and Regionalization Grant for a Shared Wastewater Management Study. The purpose of the study is to prepare an engineering assessment for a potential partnership for shared wastewater management options among the four towns utilizing the Joint Base Cape Cod (JBCC) treatment, collection and discharge system. A list of commonly used acronyms and abbreviations is included in Table 1-1.

1.2 JOINT STATEMENT AND PROJECT PREMISE

The four towns have a long and proud history of active cooperation and collaboration with their neighbors at JBCC, including such items as solid waste management (Upper Cape Regional Transfer Station) planning/contracting, groundwater contamination clean-up, Upper Cape Regional Water Supply Cooperative management, Upper Cape Water Supply Reserve Community Advisory Council, and the Cape Cod Commission's Joint Land Use Study planning. The four towns are each in various stages of wastewater management planning and implementation; however, the four towns and JBCC are interested in actively and collaboratively exploring a shared wastewater solution utilizing the JBCC wastewater facilities. This is evidenced by the joint application for the Efficiency and Regionalization Grant. The four towns, JBCC and MassDevelopment have jointly developed the following project premise to guide the preparation and review of this document:

> *The potential transfer of the JBCC wastewater facilities from the federal government to a local entity represents a significant opportunity for regional use by the surrounding towns; however, there are legal, political and financial issues to work through. The existing wastewater facilities will require short-term upgrades and will likely require significant expansion to serve the anticipated mid-term to long-term Upper Cape needs. MassDevelopment is performing a comprehensive due diligence to study the potential ownership of the facilities as the "initial management entity", anticipating transferring the facilities to a "successor management entity" in the future. The purpose of this study is to develop a framework for regionalization based on a phased implementation approach with both short-term and long-term goals in mind.*

TABLE 1-1
LIST OF COMMONLY USED ACRONYMS AND ABBREVIATIONS

ACEC	Area of Critical Environmental Concern
ANG	Air National Guard, Massachusetts (102nd Intelligence Wing)
BOD_5	Biochemical Oxygen Demand
CCC	Cape Cod Commission
Current	Representing present conditions as applied to population, wastewater flow or nitrogen load
CWMP/CWRMP	Comprehensive Wastewater Management Plan
CWNMP	Comprehensive Watershed Nitrogen Management Plan
CWRMP	Comprehensive Water Resources Management Plan
D/B/O	Design/Build/Operate contract delivery method
DEIR	Draft Environmental Impact Report
DEP	Department of Environmental Protection
DRI	Developments of Regional Impact
EIR	Environmental Impact Report
EENF	Expanded Environmental Notification Form
EOEEA	Executive Office of Energy and Environmental Affairs
ESA	Environmentally Sensitive Area
FEIR/SEIR	Final Environmental Impact Report/ Single Environmental Impact Report
Future	Referring to population, wastewater flows or nitrogen loads, expected in the future
GIS	Geographic Information System
gpd	Gallons Per Day
gpd/sf	Gallons Per Day Per Square Foot
I/I	Infiltration and Inflow
IMA	Inter-Municipal Agreement
hp	Horsepower
JBCC	Joint Base Cape Cod (aka Massachusetts Military Reservations)
kg/day	Kilograms Per Day
lb/yr	Pounds Per Year
MEP	Massachusetts Estuaries Project
MCL	Maximum Contaminant Level
MEPA	Massachusetts Environmental Policy Act
Mgal	Million gallons
Mgal/yr	Million gallons per year
mgd	Million gallons per day
mg/l	Milligrams per liter
MOU	Memorandum of Understanding
NHESP	Natural Heritage and Endangered Species Program
NPV	Net Present Value
O&M	Operations and Maintenance
RIB	Rapid Infiltration Basin
SCADA	Supervisory Control and Data Acquisition system (computer control system)
SMAST	School of Marine Science and Technology, University of Massachusetts at Dartmouth
SRF	State Revolving Fund (administered by Massachusetts Department of Environmental Protection)
TKN	Total Kjeldahl Nitrogen
TMDL	Total Maximum Daily Load
TN	Total Nitrogen
TSS	Total Suspended Solids
TWMP	Targeted Watershed Management Plan
USAF	United States Air Force
USEPA	United States Environmental Protection Agency
USGS	United States Geologic Survey
VOC	Volatile Organic Compound
WWTF	Wastewater Treatment Facility

1.3 SUMMARY OF PREVIOUS WASTEWATER PLANNING EFFORTS

The towns and JBCC/MassDevelopment have been engaged in wastewater management planning over the past decade. This section summarizes the relevant components of the previous wastewater planning efforts undertaken by each town.

1.3.1 Bourne

Bourne completed its initial town-wide Comprehensive Wastewater Management Plan in 2007. The 2007 plan estimated current and future wastewater flows and septage volumes town-wide, but focused on alternatives and solutions for the most pressing wastewater management needs on the north side of the Cape Cod Canal, including on-going discussions and negotiations with Wareham regarding its wastewater treatment inter-municipal agreement (IMA) as well as siting of supplemental treatment and disposal facilities on the north side of the Canal. Bourne has also been focused on addressing landfill leachate needs on the south side of the Canal. In the future, it is expected that Bourne will need to address nutrient-related wastewater management drivers (based on the Massachusetts Estuaries Project work) and density-of-development-related wastewater management drivers on the north and south sides of the Canal. Bourne has indicated that it is considering the long-term opportunity to transport treated effluent north of the canal to the disposal beds via a force main attached to the possible future third Cape Cod Canal bridge.

1.3.2 Falmouth

Falmouth most recently completed its Targeted Watershed Management Plan (TWMP) for Little Pond, Great Pond, Green Pond, Bournes Pond, Eel Pond and Waquoit Bay Watersheds in 2013. The TWMP proposes a sewer extension to serve Little Pond, upgrades to the Blacksmith Shop Road WWTF, an additional effluent disposal site (outside of the West Falmouth Harbor watershed), a number of demonstration projects (including aquaculture, inlet widening at Bournes Pond, eco-toilets, permeable reactive barriers, and stormwater management), and an adaptive management plan. This project received its EOEEA Certificate in 2014 and is currently being implemented.

1.3.3 Mashpee

Mashpee completed a town-wide Comprehensive Watershed Nitrogen Management Plan (CWNMP) in 2015. The CWNMP identifies a regional approach with a proposed aquaculture program, a proposed connection to the JBCC wastewater facilities, two or three proposed small decentralized WWTFs located in Mashpee, expansion/upgrades to several small existing public and private WWTFs in Mashpee, and a preliminary agreement to review nitrogen trading with Sandwich, Barnstable and potentially Falmouth. The 2015 CWNMP Final Environmental Impact Report received a MEPA Certificate from the Secretary of Energy and Environmental Affairs dated July 31, 2015. The 2015 CWNMP is under DRI review by the Cape Cod Commission. Town-wide wastewater flows were identified in the Needs Assessment Report (2007) and are summarized in the 2015 WNMP.

1.3.4 Sandwich

Sandwich is currently in the final phase of completing its town-wide Comprehensive Water Resources Management Plan (CWRMP). The CWRMP identifies a regional approach with two proposed small decentralized WWTFs located in Sandwich, a proposed connection to the JBCC wastewater facilities, and a proposed nitrogen trading program with Mashpee, Barnstable and potentially Falmouth. The draft June 2017 CWRMP will be presented for public comment over the upcoming months.

1.3.5 MassDevelopment/ JBCC

MassDevelopment, on behalf of JBCC, has completed several wastewater planning efforts – one in 2012 (CH2M-Hill) and another in 2014 (Wright-Pierce). Both planning efforts were performed looking at a potential transfer of ownership of the wastewater facilities from JBCC to MassDevelopment or another local management entity. These studies concluded that the JBCC military needs a fairly small capacity allowance for the planning period and that excess capacity could be made available to municipalities.

1.3.6 Cape Cod Commission

The Cape Cod Commission completed a Joint Land Use Study (JLUS) for JBCC in 2005 and completed the JLUS Update in 2013. The JLUS Update affirmed the potential for a military/municipal partnership through shared facilities and recommended that the excess capacity at the JBCC wastewater facilities be used for military and municipal needs.

The JLUS Update identified a potential Upper Cape wastewater and effluent capacity need of 454,000 gpd to 3,270,000 gpd within a 20-year planning period (Executive Summary, Table 5). This table cites the 2012 CH2M-Hill study which was prepared for MassDevelopment, as described above.

The Cape Cod Commission completed its 208 Plan Update (Cape Cod Area Wide Water Quality Management Plan Update) in 2015. One general outcome of the 208 Plan Update is that it provides a technical framework for municipalities to incorporate non-traditional nitrogen control methods into wastewater management planning. Each of the four towns is exploring non-traditional nitrogen control methods to varying degrees in accordance with the framework provided by the 208 Plan Update which, if successful, may postpone or eliminate the need for traditional wastewater infrastructure in certain portions of the respective towns. This will likely result in a longer planning period to reach the upper limit flow projections previously identified in the 2012 CH2M-Hill study and JLUS Update study (say 40 to 50 years, rather than the 20 years used in the 2012 report).

Lastly, the 208 Plan Update has two specific recommendations regarding the JBCC wastewater facilities (Section 7):

- Recommendation S7.1 – "The Cape Cod Commission shall continue discussion and coordination with JBCC and MassDevelopment regarding wastewater allocation policy for the base."
- Recommendation S7.1 – "The Military should ensure that future development within the cantonment area be connected to the JBCC wastewater treatment plant wherever feasible."

The Cape Cod Commission completed an analysis of septage disposal need in 2016. The study estimated the volume of septage generated on Cape Cod (i.e., 52.8 Mgal/year) as well as the septage treatment capacity on Cape Cod (i.e., 53.3 Mgal/year, which excludes the recently closed Tri-Town Septage Treatment Plant). This analysis did not identify the volume of septage generated by each town on Cape Cod. [CCC/AECOM Task Order #12D Technical Memorandum on Barnstable County Septage Analysis, Table 2-2 and 3-1 (Rev Sept 30, 2016)]

1.3.7 Summary of Key Data for Wastewater Planning

The following definitions are applicable to the information in this table:

- Current Wastewater Flow is the estimated or known wastewater for pre-2017 conditions, based on town documentation or input. These flows are intended to represent the general population, level of commercial activity and wastewater generation rates that exist today.
- Theoretical Build-Out is the population, commercial activity, and wastewater flow associated with the ultimate development in each town, to the fullest extent possible under current zoning and other regulation, regardless of economic issues.
- Practical Build-Out is the population, commercial activity and wastewater flow associated with more realistic assumptions on the extent of build-out, factoring in such concerns as economic realities, other limitations on growth (such as infrastructure capacity), land protection efforts, and retention of estate properties.
- Planning Horizon is the population, commercial activity, and wastewater flow that will serve as the basis for this planning effort. The planning horizon for this study is 20 years.
- Future Wastewater Flow is the estimated wastewater flow at the "planning-horizon" identified in town documentation.

A summary of key data for each town is presented in Table 1-2, including "current wastewater flow" and "future wastewater flow".

TABLE 1-2: KEY DATA FOR PARTICIPATING TOWNS AND JBCC

	Bourne	Falmouth	Mashpee	Sandwich	JBCC
Population (2010)	19,754	31,531	14,006	20,675	~3,500
Area of Land and Water (TW)	52.9 sq mi.	48.8 sq mi.	27.2 sq mi.	44.2 sq mi.	~22,000 ac
Current Wastewater Flow (TW,AA)	2,200,000 gpd	4,000,000 gpd	1,136,000 gpd	1,667,000 gpd	140,000 gpd
Current Wastewater Flow to WWTFs (TW,AA)	110,000 gpd (Wareham)	440,000 gpd (Falmouth)	180,000 gpd	0 gpd	140,000 gpd (JBCC)
Current Septage Volume (TW,AA)	4.1 Mgal/yr	8.0 Mgal/yr	2.7 Mgal/yr	3.9 Mgal/yr	0 Mgal/yr
Future Wastewater Flow (TW,AA)	3,751,000 gpd	4,000,000 gpd	2,007,000 gpd	2,164,000 gpd	152,000 gpd
Future Wastewater Flow to WWTFs (TW,AA)	1,061,000 to 1,782,000 gpd	750,000 to 2,200,000 gpd	1,076,000 to 1,776,000 gpd	540,000 to 900,000 gpd	152,000 gpd
Future Septage Volume (TW,AA)	6.2 Mgal/yr	9.5 Mgal/yr	1.5 Mgal/yr	5.1 Mgal/yr	0 Mgal/yr
Town-Wide Wastewater Planning Year Completed, Firm	2007 Tighe&Bond	2013 GHD	2015 GHD	2017 Wright-Pierce	2012 CH2M-Hill 2014 Wright-Pierce

Notes:
1.) See report text on previous page for definitions.
2.) 2010 Population – 2010 US Census (municipalities) and 2009 JBCC Base population survey.
3.) Area of land and water based on Wikipedia.
4.) TW = “all town-wide whether to an on-site system or a WWTF”; AA = annual average basis
5.) Falmouth’s Little Pond Sewer Service Area flow will increase the existing annual average flow to 710,000 gpd when completed.

1.4 DESCRIPTION OF EXISTING JBCC WASTEWATER FACILITIES

This section of the report describes the existing JBCC wastewater system, the current wastewater flows and loadings, and the overall facility condition assessment for the JBCC wastewater system.

1.4.1 Overall System

The existing JBCC wastewater system provides service for on-base facilities. It is currently owned by the United States Air Force (USAF) and is currently operated and maintained by the Massachusetts Air National Guard 102nd Intelligence Wing (ANG). The existing JBCC wastewater system is shown on Figure 1-1. The major components of the existing wastewater treatment system are summarized in Table 1-3.

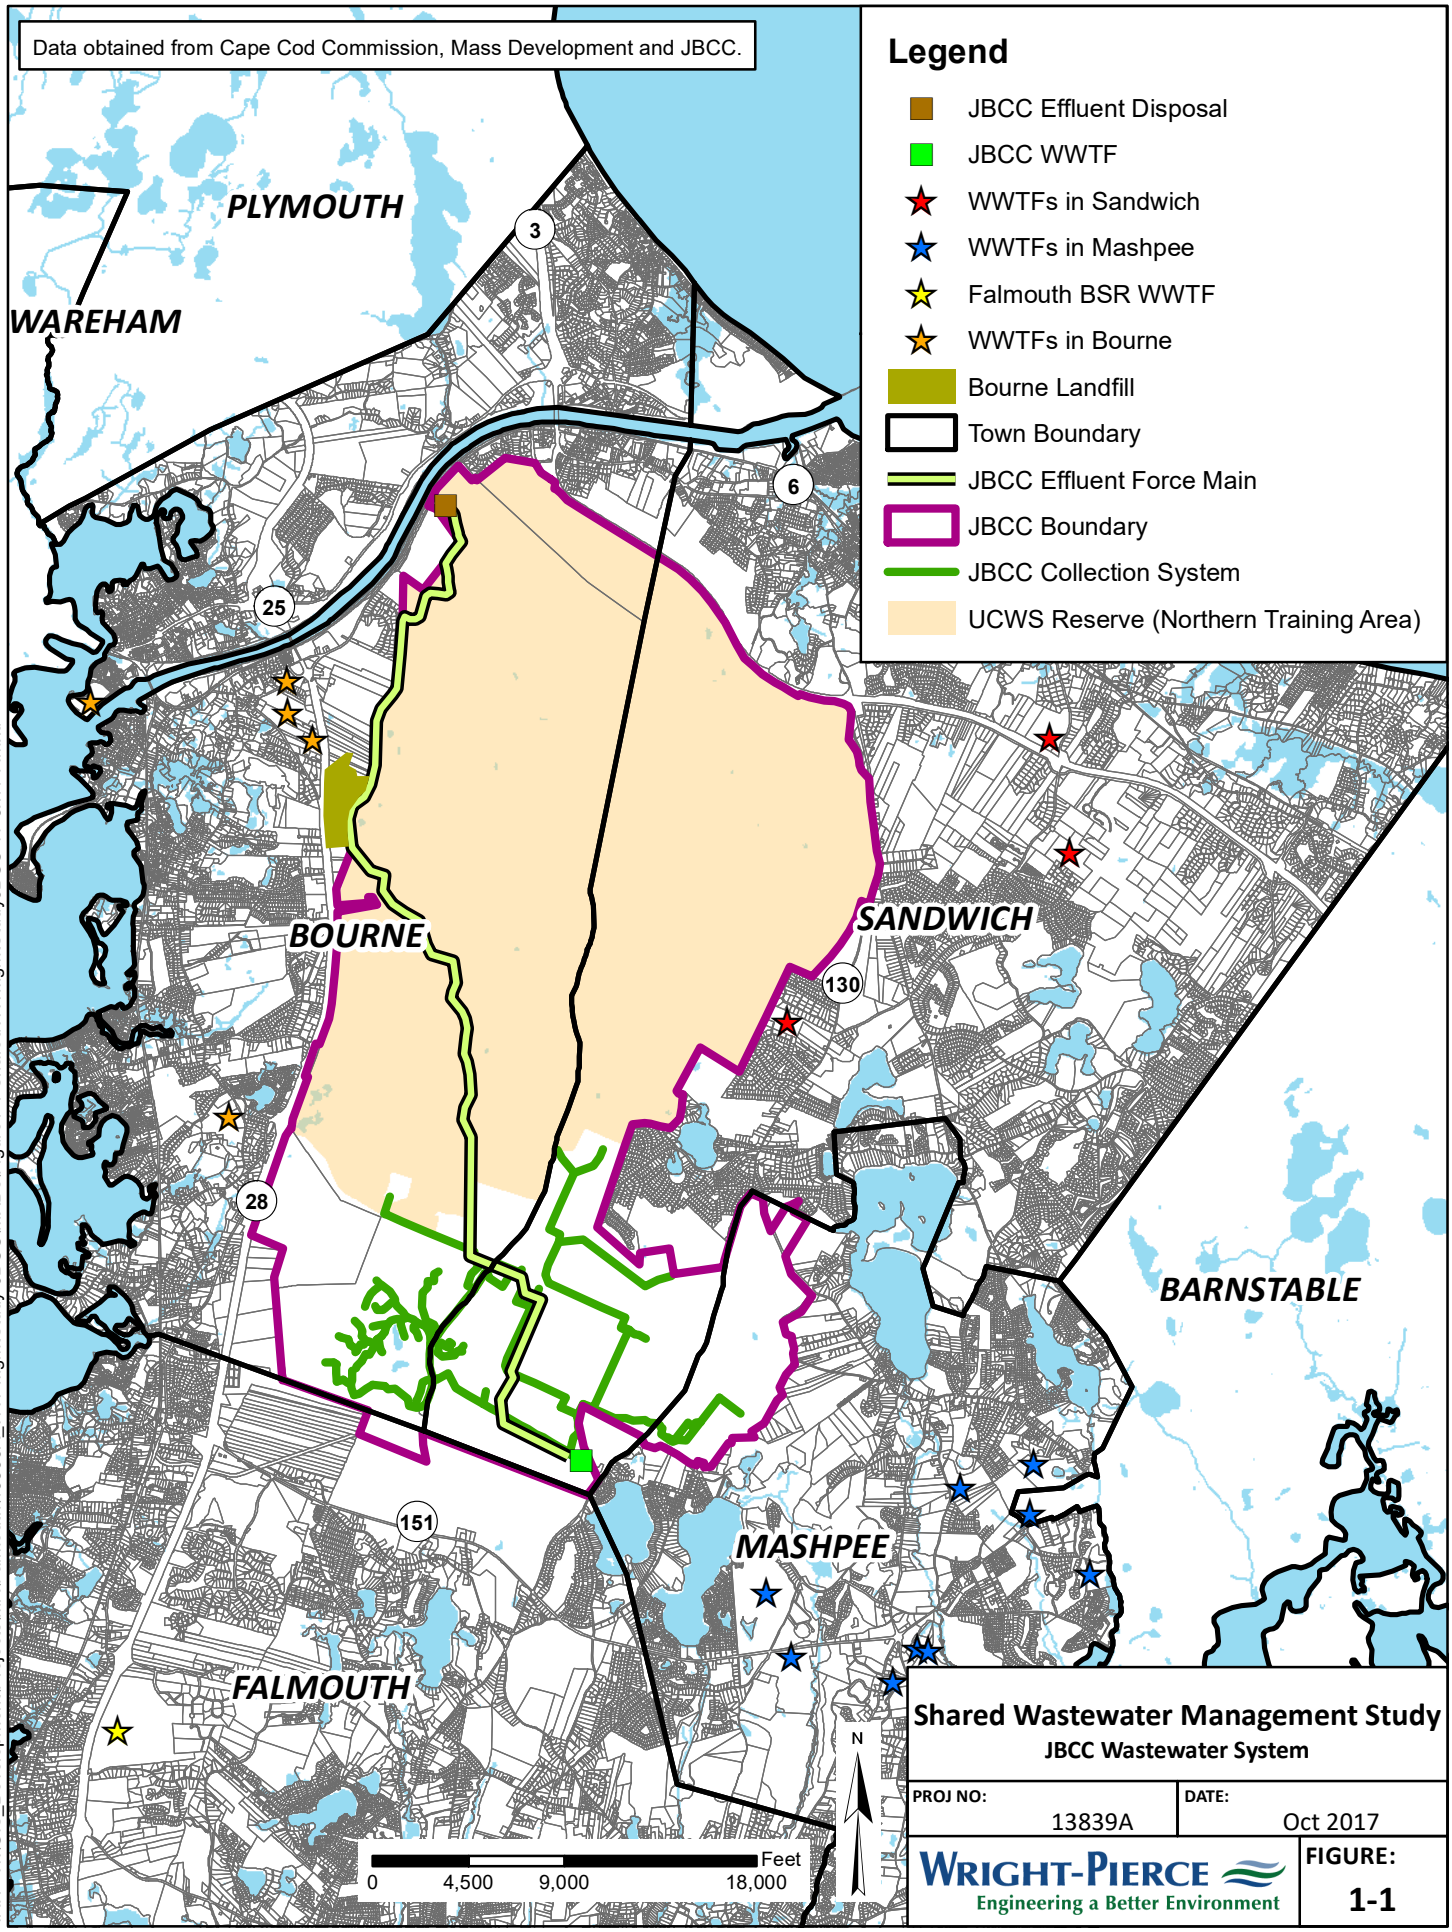
The WWTF and all of the collection system are located within the Cantonment Area, which comprises approximately 25% of JBCC. Most of the effluent force main and the entire effluent disposal system are located in the Upper Cape Water Supply Reserve, which comprises the northerly 75% of JBCC.

1.4.2 Wastewater Flows and Loads

The wastewater flows and loads for the period 2008 to 2012 and for the period 2012 to 2014 are summarized in Table 1-4. Based on this information, the WWTF is operating at just under 50% of its design capacity.

1.4.3 Collection System

The collection system was built when the population served was approximately 70,000; whereas, there is currently a population served of approximately 3,500 (JBCC Base Population Survey, 2009). The collection system includes 11 pumping stations and approximately 30.5 miles of sewers ranging in size from 6-inch to 24-inch diameter including several pipe materials. The collection system was constructed between the 1940s and present.



Shared Wastewater Management Study

JBCC Wastewater System

FIGURE: 1-1

TABLE 1-3
WASTEWATER SYSTEM COMPONENTS

Component	Quantity
Collection & Conveyance	161,000 linear feet sewers, 595 manholes
Pump Stations	11
Wastewater Treatment Facility	360,000 gpd
Effluent Force Main	55,280 linear feet
Rapid Infiltration Disposal Beds (RIBs)	4 cells, 6 acres
Monitoring Wells for RIB Compliance:	4
Composting Facilities (abandoned)	25,290 square feet

TABLE 1-4
CURRENT WWTF FLOWS AND LOADINGS

Parameter	Condition	Design Rating	Permit Value	Current 2008 to 2012	Current 2012 to 2014
Flow (gpd)	Annual Average	300,000	360,000 (1)	143,000	131,000
	Maximum Month	430,000	-	248,500	210,000
	Maximum Day	800,000	840,000	555,600	390,000
	Peak Hourly	1,380,000	-	-	-
BOD Load (lb/day)	Annual Average	690	-	337	-
	Maximum Month	990	-	548	-
	Maximum Week	1840	-	948	-
TSS Load (lb/day)	Annual Average	550	-	272	-
	Maximum Month	790	-	453	-
	Maximum Week	1470	-	884	-
TKN Load (lb/day)	Annual Average	125	-	60	-
	Maximum Month	180	-	104	-
	Maximum Week	335	-	233	-
Ammonia Load (lb/day)	Annual Average	90	-	43	-
	Maximum Month	125	-	76	-
	Maximum Week	235	-	163	-

Notes:
1) 12-month rolling average flow.
2) Data in "Design Rating" and "Current 2008 to 2012" columns are from CH2M-Hill, 2012.

1.4.4 Wastewater Treatment Facility

The WWTF is an extended aeration activated sludge facility (biological nitrogen removal) with disinfection that was constructed in 1995. The WWTF was constructed with a capacity of 300,000 gpd (annual average); however, when the Barnstable County Jail was constructed in the early 2000s, the WWTF was upgraded to a design capacity of 360,000 gpd (annual average). The WWTF design maximum day flow of 840,000 gpd. Major unit processes at the WWTF include:

- Preliminary Treatment (screening and grit removal)
- Advanced secondary treatment (biological nutrient removal)
- Disinfection
- Effluent Pumping
- Sludge Holding and Aeration
- Sludge Decanting
- Biosolids hauling (for off-site processing and disposal)

1.4.5 Effluent Force Main

The existing effluent force main is a 12-inch diameter ductile iron pipe that runs approximately 10.5 miles from the WWTF, through the Reserve, to the Rapid Infiltration Basins (located at the northwest edge of JBCC). There is a short section of 8-inch diameter ductile iron pipe (at 5.5% slope) between Static Head Structure No.1 and the Hydraulic Distribution Structure. The force main is shown on the design drawings entitled "Effluent Force main and Infiltration Basins" (CDM/SAIC, 1993). The force main is hydraulically complex and has approximately 20 air and/or vacuum relief valves. Based on the existing pumping system design, the effluent disposal force main has a design capacity of 1,400,000 gpd on a peak hour basis (i.e., 2.8 feet per second). This capacity could potentially be increased to 1,750,000 gpd on a peak hour basis; however, some modifications to the pumping/surging suppression system would be required. Increases beyond that flow rate would require additional piping in parallel. Additional analysis on this item will be required.

1.4.6 Rapid Infiltration Basins

The existing effluent disposal facility consists of four rapid infiltration basins (RIBs), with a total surface area of 259,160 square feet. The RIBs were constructed on the basis of design drawings

entitled “Effluent Forcemain and Infiltration Basins” (CDM/SAIC, 1993) as well as a *Hydrogeologic Investigation and Design Effluent Infiltration Basins* technical memorandum (CDM/SAIC, 1993). The existing RIBs are in very good condition with the only reported operational challenge being the control of vegetation growth. There are no reports of “effluent breakout” occurring downgradient of the RIBs. DEP has not identified the Cape Cod Canal as nitrogen-sensitive. A preliminary review of the design surficial loading rates and the groundwater mound elevations indicates that the sizing of the RIBs is conservative and that additional capacity can likely be obtained through a re-permitting and re-rating process with DEP. This will need to reviewed closely with DEP.

1.4.7 Groundwater Discharge Permit Requirements

The WWTF effluent quality requirements are contained in a Groundwater Discharge Permit (GWDP) which is issued by the Massachusetts Department of Environmental Protection (DEP). The GWDP (Application/Permit No. 41-3) allows for disposal of suitable quality effluent up to 360,000 gpd on a 12-month rolling average basis and up to a maximum of 840,000 gpd on any given day (so-called “maximum day flow”). The GWDP is included in Appendix A and its requirements for the WWTF effluent are summarized in Table 1-5. The GWDP requirements for groundwater monitoring at the RIB site are summarized in Table 1-6. The current permit expires in April 2018 and a renewal application is due in October 2017. As a part of this impending GWDP renewal process, JBCC should request that the “maximum day flow of 840,000 gpd” be revised to a “maximum flow of 840,000 gpd based on a 3-day rolling average”.

1.4.8 Facility Condition

The JBCC WWTF was operational in 1995 and now just over 20 years old. A comprehensive upgrade for the facility should be expected within the next 10 years. In the interim, the facility will require modest upgrades and investments in order to maintain reliability of treatment performance and permit compliance, to better utilize its existing available capacity and to reduce annual operations and maintenance costs. Several baseline improvements were identified for this purpose in the 2014 JBCC Water and Wastewater System Evaluation, including:

- Provide off-line influent equalization tank and a pump station to aid in peak flow management. Set equalization volume at 100,000 gallons.

TABLE 1-5
GWDP – WWTF EFFLUENT LIMITS AND MONITORING REQUIREMENTS

Parameter	Discharge Limitation	Minimum Frequency
Flow, 12-month moving average	360,000 gpd	Daily
Flow, maximum day	840,000 gpd	Daily
Oil and grease	15 mg/l	Monthly
Total Suspended Solids (TSS)	30 mg/l	Monthly
Total Nitrogen (NO2-N + NO3-N + TKN)	10 mg/l	Monthly
Nitrate-Nitrogen (NO3-N)	10 mg/l	Monthly

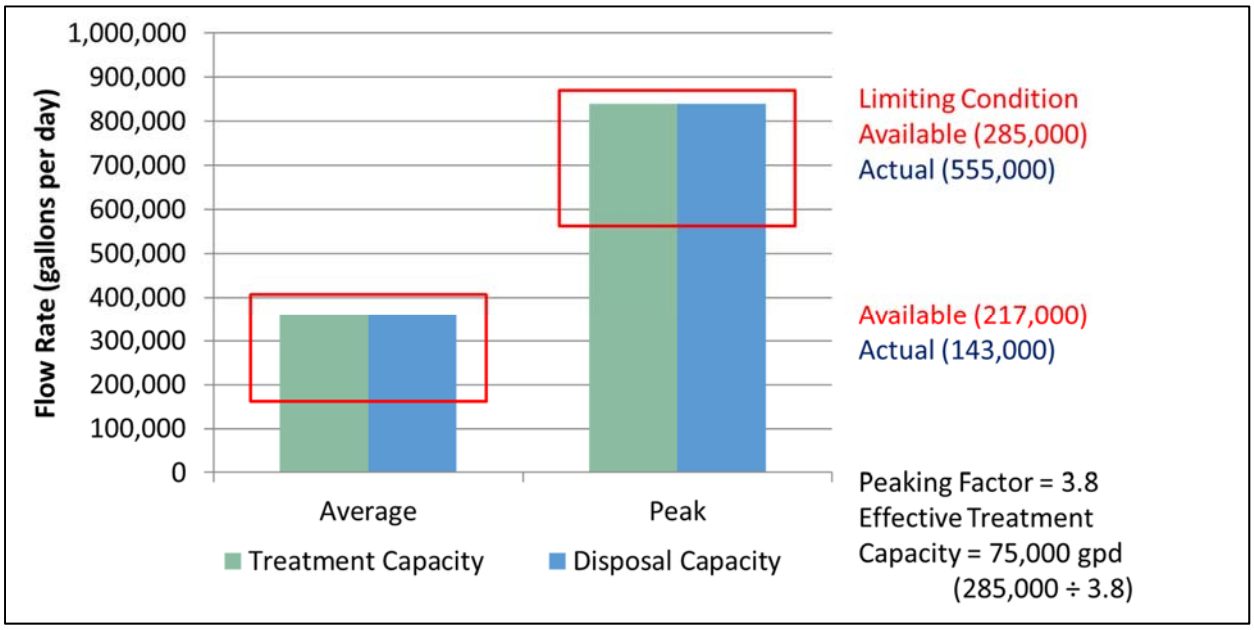
- Install a small supplemental carbon system (i.e., glycerin) including 500-gallon storage tank, one chemical feed pump, instrumentation interface with SCADA and electrical feeds.
- Install a rotary disc or drum thickener over the existing Sludge Storage Tanks and enclose it in a small building. Automate sludge wasting and polymer feed system to pre-thicken waste sludge prior to storage.
- Replace existing sludge feed pumps (progressing cavity) with higher rate sludge feed pumps (rotary lobe) to convey thickened sludge to a tanker truck at high rate (say 200 gpm) to allow for shorter truck fill times. Add new truck fill piping with quick-connect to building exterior.
- Upgrade components of the effluent forcemain. Increase the diameter of 180 feet of pipe from 8-inch to 18-inch between Static Head Structure No. 1 to Hydraulic Distribution Structure at the RIB site (the remainder of the forcemain is 12-inch diameter). Replace all existing air/vacuum release valves and add a surge tank at the Frank Perkins Road Static Head Structure).

1.4.9 Estimate of Existing Available Capacity

Based on the WWTF design capacity and the 2008 to 2012 flows and loads, the WWTF has approximately **157,000 gpd (annual average)** of residual capacity which can be made available to neighboring communities or users on the base.

On an annual average basis, the effluent disposal system also has approximately 157,000 gpd of additional capacity. On a peak day basis (due to the impacts of inflow), the effluent disposal system has approximately 285,000 gpd of additional capacity. Given that the existing peaking factor for peak to average flows is 3.8:1 (again, due primarily to the impacts of inflow), the *effective available capacity* is approximately **75,000 gpd (annual average basis)**. It is important to note this *effective capacity* is less than that available at the WWTF. Without inflow control, available treatment capacity will go unused due to the limitations inherent in the GWDP. The capacity and effective capacity is illustrated on Figure 1-2.

FIGURE 1-2
ESTIMATE OF EXISTING AVAILABLE CAPACITY



This existing available capacity can be made available to neighboring communities or to new users which may be located on JBCC. From a regionalization perspective, it is very important to maximize the available capacity. This available capacity can be maximized by one or more of the following methods:

- Aggressively investigating and removing collection system inflow sources;
- Securing customers with low wastewater flow "peaking factors" (i.e., customers with a peak flow that is similar to the average flow);
- Seeking opportunities for beneficial reuse of effluent;
- Providing influent flow equalization at the WWTF;
- Addressing the effluent force main capacity limitation; and/or
- Increasing the capacity of the disposal system by re-rating the RIBs and revising the GWDP with DEP review and approval.

1.5 REGULATORY FRAMEWORK

1.5.1 Effluent Disposal

The existing GWDP is focused primarily on addressing conventional parameters (BOD, TSS, bacteria) as well as nutrients (nitrogen, phosphorus). Over time, additional parameters or more stringent effluent limits may be imposed.

- Nitrogen – DEP has indicated that there is no intention to revise the effluent nitrogen limits for the JBCC GWDP at this time. DEP has also indicated that there is no Total Maximum Daily Load (TMDL) Study completed or planned because the effluent disposal site is not located in a nitrogen-sensitive watershed. Given that the RIBs are located in a non-nitrogen-sensitive watershed (Canal South), the imposition of a more stringent nitrogen limit is unlikely.
- Phosphorus – DEP has not indicated any intention to add a phosphorus limit at this time. Given the location of the discharge, the imposition of a phosphorus limit is very unlikely.
- Compounds of emerging concern (CECs) – CECs encompass a wide variety of compounds including endocrine disrupting compounds, pharmaceuticals, flame retardants, hormones, industrial solvents and surfactants, metals, pesticides, and personal care products. CECs have been found in wastewater for decades; however, they have recently reached the forefront of regulatory and public concern, and there is currently a great deal of research on CECs. One of the difficulties associated with addressing this topic is the large number and wide array of substances that can be classified as CECs. Given that the location of the discharge is outside water supply recharge areas, the short-term imposition of CEC limits is very unlikely. DEP has developed regulatory limits for Total Organic Carbon (an indicator of CEC's) for groundwater discharges within a Zone II of a public water supply, but there is no indication that limits will be extended to other groundwater categories.

Future effluent limits will be dictated by the disposal location and by potential changes in environmental policy over time. While capital upgrades would be required if the GWDP requirements were made more stringent, this eventuality appears unlikely within a 10- to 20-year timeframe. Refer to Section 2 for additional description of permit considers based on alternative effluent disposal methods.

To the extent that sufficient capacity can be obtained via RIB expansion, DEP will consider this a better environmental solution than a surface water discharge to the Cape Cod Canal and should be achievable at less cost and regulatory complexity. If sufficient capacity cannot be obtained via the existing or expanded RIBs, then alternative methods will need to be considered (e.g., deep well injection, surface outfall to the Cape Cod Canal, etc.).

1.5.2 Total Maximum Daily Loads for Nitrogen

The DEP and the Massachusetts Estuaries Project (MEP) have no plans to study the Cape Cod Canal at this time; however, the DEP and MEP have studied many of the Upper Cape watersheds and have developed Total Maximum Daily Load (TMDL) Studies on many of the studied watersheds. TMDLs may require that towns consider off-site wastewater management at more locations than currently considered or at greater flow rates than currently anticipated in this or previous studies. The elimination of private septic systems will increase the amount of wastewater flow requiring off-site wastewater management at WWTFs.

1.5.3 Municipal Reviews

Each municipality needs to review and approve its participation in a regional solution. The review would occur at a technical level (department heads and review boards) and an executive level (boards of selectmen and town meeting).

1.5.4 Cape Cod Commission

The Cape Cod Commission will need to review and approve any proposed regional project of the nature described in this document for consistency with the 208 Plan Update.

1.5.5 Massachusetts DEP and United States EPA

The DEP will need to review and approve proposed/requested capacity increases for the JBCC wastewater facilities. DEP will also need to address the issue of multiple permittees and effluent sources discharging to a single effluent disposal location (e.g., joint and several responsibilities related to monitoring requirements, maintenance requirements, etc.). EPA involvement is not anticipated unless there is a proposed surface water discharge to the Cape Cod Canal.

1.5.6 Upper Cape Water Supply Reserve/ Northern Training Area

The Upper Cape Water Supply Reserve (the "Reserve", also known as the "Northern Training Area") is located in the northern portion JBCC and is approximately 15,000 acres. The Reserve was created in 2001 to 2002 to protect the drinking water supply and wildlife habitat. The Reserve is governed by the Environmental Management Commission (3 members) and is advised by the Community Advisory Council (15 members). All activities in the Reserve are subject to Environmental Performance Standards and are subject to the approval of the Environmental Management Commission. The effluent force main and the RIBs are both within the Reserve. Also, the proposed effluent pipe connection from Bourne and Falmouth would cross the Reserve.

1.6 PRELIMINARY STRATEGY FOR REGIONAL APPROACH

1.6.1 Project Planning Horizon

The project planning horizon was agreed to be 20 years; however, the conceptual alternatives identified and evaluated in this report will also consider future expansion potential beyond the 20-year time frame.

1.6.2 Potential Opportunities, Challenges and Logistical Issues

There are many opportunities associated with regional wastewater facilities at the JBCC location. There are also a number of legal, political and financial challenges to overcome for the wastewater facilities to be shared. These opportunities and challenges are summarized in **Figure 1-3**.

1.6.3 Potential Phasing Framework

The use of excess capacity at JBCC by adjacent municipalities has been identified as an 'ideal option' for over a decade. If this concept were straight-forward, it would already be underway or completed. Given the complexity of this endeavor, a multi-phase implementation framework is most advantageous. A potential phasing framework is summarized below.

FIGURE 1-3 OPPORTUNITIES AND CHALLENGES FOR SHARED WASTEWATER FACILITIES AT JBCC

Opportunities

- Central location in Upper Cape
- History of collaboration among Bourne, Falmouth, Mashpee, Sandwich and JBCC
- Existing wastewater collection, treatment and disposal facilities
- Disposal in non-nitrogen-sensitive watershed
- Potential regional solution for septage and potential source of operating revenue
- Easement across the UCWSR for effluent connection from Bourne is almost approved
- Rail spur on JBCC, existing contract with SEMASS
- Preservation of military mission
- Preservation/protection of federally designated sole-source aquifer
- Extensive land area, lack of abutters
- Consensus from JBCC, municipalities, DEP and CCC on benefits
- Potential future regional solutions for biosolids and/or source-separated organics digestion
- Potential capital and O&M cost savings due to efficiencies gained by economies of scale

Challenges

- Complicated land ownership/lease arrangements
- Different needs, goals and implementation timelines among towns and JBCC
- Shared military/ civilian facilities
- Capacity limitations of existing wastewater infrastructure
- Identification of mutually agreeable successor management entity to run facilities
- Land use restrictions in the Upper Cape Water Supply Reserve area
- Inconsistent WWTF performance
- Re-permitting of RIBs to receive different types of flow (e.g., municipal sewage vs treated landfill leachate) and flow from different communities
- Development of sustainable cost structure for future operations.
- Future changes in effluent limits or regulatory drivers (e.g., phosphorus, CECs)
- Potential third-party or non-governmental entity influence on the proposed project based on increased effluent flows and loadings to the Cape Cod Canal, Cape Cod Bay and Buzzards Bay.

Phase 1/ Year 0 to Year 5:

- Develop partnership and IMAs/IGAs with matrix of future flows
- Confirm initial management entity
- Transfer facility to initial management entity
- Development of full-build wastewater master plan
- Design and permitting of Phase 2 wastewater improvements
- Develop rate structure, sewer use ordinance, inter-municipal agreements, permit modifications, etc.

Phase 2/ Year 5 to Year 10:

- Complete construction of initial treatment and disposal upgrades for short-term and mid-term needs.
- Begin municipal connections.
- Create successor management entity (to be determined, refer to Section 3).
- Transfer facility to successor management entity.
- Design and permitting of Phase 3 wastewater improvements
- Continue municipal connections.

Phase 3/ Year 10 to Year 20:

- Complete construction of treatment and disposal upgrades for long-term needs.
- Continue municipal connections.

1.6.4 Options for Inter-Governmental Agreements and Management Entity

Inter-Governmental Agreements

The Upper Cape communities have previously developed inter-municipal agreements and it is expected that this will be a viable option for formalizing "next steps" among the towns. JBCC will also need to be a party to an inter-governmental agreement if this partnership were to proceed.

Management Entity

Previous studies have evaluated potential management models to allow for shared use of the wastewater facilities (CH2M-Hill, 2012). The current study presumes that an "initial management entity" will take over ownership of the wastewater facilities and manage the technical and financial aspects of the project until a "successor management entity" is established.

An initial list of potential successor management entities includes: 1) MassDevelopment; 2) one of the towns (Bourne, Falmouth, Mashpee or Sandwich); or 3) an existing or new special purpose district (e.g., the Upper Cape Regional Water Supply Collaborative). These options are evaluated further in Section 2 of this report.

1.6.5 Requested Capacity by Wastewater Type

Each of the towns and JBCC has provided capacity requests by wastewater type to address wastewater management needs including Nitrogen TMDL compliance. For the purposes of this study, the following terms will be used for this study for the wastewater types:

- ***Sewage*** is residential/commercial/light industrial wastewater collected and conveyed to the JBCC WWTF for treatment and disposal.
- ***Effluent*** is treated wastewater. References to "effluent disposal only" mean that the wastewater will be treated elsewhere (e.g., the Integrated Solids Waste Management or "ISWM" WWTF) and the effluent will be conveyed to the JBCC disposal system via the existing forcemain (i.e., not treated at the JBCC WWTF).
- ***Leachate*** is from the Bourne ISWM landfill.
- ***Leachate effluent*** is leachate treated at the proposed Bourne ISWM WWTF.
- ***Septage*** is the liquid/sludge mixture pumped from septic tanks.

At the project kick-off meeting, all towns agreed that including an allocation for receiving and treating septage at the JBCC WWTF is appropriate for this study. Accordingly, the "current condition" septage flows indicated in Table 1-2 will be used in the analysis moving forward as it is anticipated that increase in septage volume from non-sewered growth will offset the reduction in septage volume from current structures being connected to sewer.

Bourne

- Study Basis: The study basis includes the following key assumptions:
    1. Wastewater flow does not cross the Cape Cod Canal.
    2. Leachate effluent from the Bourne "ISWM WWTF" is connected to the JBCC effluent forcemain and disposal system (i.e., 100,000 gpd) in the short-term.
    3. Wastewater flow from Bourne wastewater planning areas 8, 9, 10, 12, 13, and 14 goes to the ISWM WWTF for co-treatment with landfill leachate and the effluent is directed to the JBCC effluent forcemain and disposal system in the mid-term and long-term. The ISWM WWTF would need to be designed for co-treatment under this approach.
    4. Wastewater flow from Bourne wastewater planning areas 15 through 20 goes to the JBCC WWTF location and is treated as sewage in the mid-term and long-term.
    5. Wastewater flow from Bourne wastewater planning area 11 (MacArthur Boulevard/Route 28) is split equally between the ISWM WWTF and the JBCC WWTF.
    6. Wastewater flows connected to sewer are estimated based on the priority assigned to the wastewater planning areas in the 2007 Tighe & Bond study
    7. Septage treatment capacity is provided at the JBCC WWTF.
- Low End: The low end estimate includes the following assumptions:
    1. Leachate effluent from the Bourne "ISWM WWTF" is connected to the JBCC effluent forcemain and disposal system (i.e., 100,000 gpd) in the short-term.
    2. A maximum of 100,000 gpd of wastewater flow from Bourne wastewater planning areas 8, 9, 10, 12, 13, and 14 goes to the ISWM WWTF for co-treatment with landfill leachate and the effluent is directed to the JBCC effluent forcemain and disposal system in the mid-term and long-term.
    3. Septage treatment capacity is provided at the JBCC WWTF.
- High End: Same elements/flows/volumes as the study basis.

Falmouth

- Study Basis: The study basis includes the following key assumptions:
    1. Some/most of the effluent from the existing Blacksmith Shop Road WWTF is directed to the JBCC effluent forcemain and disposal system. Specifically, in the mid-term, the BSR WWTF is assumed to receive and treat 1,200,000 gpd, of which 710,000 gpd of

effluent will go to the existing BSR WWTF RIBs and 490,000 gpd of effluent will go to the JBCC effluent disposal system. In the long-term, the BSR WWTF is assumed to receive and treat 2,200,000 gpd, of which 710,000 gpd of effluent will go to the existing BSR WWTF RIBs and 1,490,000 gpd of effluent will go to the JBCC effluent disposal system.

2. Septage treatment capacity is provided at the JBCC WWTF [Note, this is a conceptual scenario, Falmouth does not have any plans to terminate septage receiving at the BSR WWTF at this time].

- Low End: Same elements; however, less effluent is directed to the JBCC effluent forcemain and disposal system in the mid-term and the long-term.
- High End: The high end assumes that all effluent flow goes to the JBCC effluent disposal system in the mid-term and that the BSR WWTF is eventually abandoned and all Falmouth wastewater flow is directed to the JBCC WWTF in the long-term. Septage also goes to the JBCC WWTF.

Mashpee

- Study Basis: The study basis includes the following key assumptions:
    1. A specified amount of sewage from Mashpee will be directed to the JBCC WWTF
    2. Septage treatment capacity is provided at the JBCC WWTF.
- Low End: Same elements/flows/volumes as the study basis.
- High End: Same elements; however, more sewage is directed to the JBCC WWTF.

Sandwich

- Study Basis: The study basis includes the following key assumptions:
    1. A specified amount of sewage from Sandwich will be directed to the JBCC WWTF. For the study basis, the amount of capacity requested is equivalent to the capacity identified for the JBCC WWTF and the proposed so-called "IWS WWTF" in CWRMP Plan B.
    2. Septage treatment capacity is provided at the JBCC WWTF.
- Low End: Same elements, however, the amount of capacity is reduced to just the amount identified for the JBCC WWTF in CWRMP Plan B.

- High End: Same elements, however, the amount of capacity is reduced to the amount identified in for the JBCC WWTF, the proposed "IWS WWTF" and the proposed "CS WWTF" in CWRMP Plan A (fully traditional backup plan).

JBCC

- Study Basis: Future flow from military and non-military users was estimated to be 7,000 gpd (CH2M-Hill, 2012). This future flow is utilized herein.
- Low End/ High End: Same elements as the study basis.

A summary of the capacity requests is provided in Table 1-7.

TABLE 1-7: REQUESTED CAPACITY BY WASTEWATER TYPE

1.6.6 Capacity Needs at Planning Horizon

Based on our review of the four towns and JBCC wastewater needs, we have developed a summary of the capacity needs by entity of the 20-year planning horizon in Table 1-8. All flows are presented on an annual average flow basis.

- The short-term capacity needs can be met with a 0% increase in treatment capacity and a 28% increase in disposal capacity.
- The mid-term capacity needs will require a 111% increase in treatment capacity and a 372% increase in disposal capacity.
- The long-term capacity needs will require a 233% increase in treatment capacity and a 831% increase in disposal capacity.

TABLE 1-8: SUMMARY OF CAPACITY REQUESTS USED IN ENGINEERING ASSESSMENT

	Capacity Requested - Annual Average Flows (gpd)							
	JBCC	**Bourne**	**Falmouth**	**Mashpee**	**Sandwich**	**Total**	**Capacity Provided**	**% Increase Existing Capacity**
Existing								
Sewage Treatment	140,000	0	0	0	0	140,000	**360,000**	n/a
Septage Treatment	0	0	0	0	0	0		
Effluent Disposal Only	0	0	0	0	0	0		
Effluent Disposal	140,000	0	0	0	0	140,000	**360,000**	n/a
Short-Term (5-year)								
Sewage Treatment	147,000	0	0	200,000	0	347,000	**360,000**	0%
Septage Treatment	0	0	0	0	0	0		
Effluent Disposal Only	0	100,000	0	0	0	100,000		
Effluent Disposal	147,000	100,000	0	200,000	0	447,000	**460,000**	28%
Mid-Term (10 year)								
Sewage Treatment	147,000	259,000	0	200,000	100,000	706,000	**760,000**	111%
Septage Treatment	0	11,000	22,000	3,000	10,000	46,000		
Effluent Disposal Only	0	444,000	490,000	0	0	934,000		
Effluent Disposal	147,000	714,000	512,000	203,000	110,000	1,686,000	**1,700,000**	372%
Long-Term (20 year)								
Sewage Treatment	147,000	456,000	0	200,000	340,000	1,143,000	**1,200,000**	233%
Septage Treatment	0	11,000	22,000	3,000	10,000	46,000		
Effluent Disposal Only	0	651,000	1,490,000	0	0	2,141,000		
Effluent Disposal	147,000	1,118,000	1,512,000	203,000	350,000	3,330,000	**3,350,000**	831%
Notes	1	1	1	1	1		2, 4	3

1) Refer to Table 1-7 for additional information.

2) Existing Capacity based on WP 2014, GWDP and WWTF O&M.

3) Capacity for Short-Term, Mid-Term and Long-Term conditions are increases over the existing capacity.

4) Organic loading treatment capacity will need to account for concentrated nature of septage.

SECTION 2

ENGINEERING ASSESSMENT

2.1 INTRODUCTION

Section 1 of this report summarizes the previous wastewater planning efforts and capacity needs for each of the participating entities. This section of the report identifies and evaluates the technical factors, costs and management considerations associated with potential shared wastewater facilities at JBCC.

2.2 WASTEWATER FLOWS USED IN THE ENGINEERING ASSESSMENT

Different components of a wastewater system are designed based on different process conditions (e.g., minimum day, annual average, maximum month, maximum multi-day, maximum day and peak instantaneous, etc.). In the absence of existing data on short-term peak flows, peaking factors are typically utilized to establish the other conditions. For the purposes of this study:

- Sewage peaking factors were established using the TR-16 Guides for the Design of Wastewater Treatment Works curves entitled "Relation of Extreme Discharges on Maximum and Minimum Days to the Average Daily Discharge of Domestic Sewage" (New England Interstate Water Pollution Control Commission, 2016) and were adjusted upward by 0.2 to account for seasonal population/flow variations on Cape Cod. Septage peaking factors were set assuming that equalization tanks would be provided.
- Effluent-only peaking factors were estimated by assuming that the remote facilities (i.e., BSR WWTF and ISWM WWTF) have, or will have, effluent equalization tanks sized to meet these peaking factor limitations or will utilize existing or new effluent disposal systems local to the ISWM and BSR WWTFs to manage peak flows.

Table 2-1 summarizes the peaking factors which have been used for this project. The peaking factors from Table 2-1 were applied to the annual average flows from Table 1-8 in order to establish the wastewater flows that will be used for this engineering assessment. Table 2-2 summarizes the annual average, maximum 3-day flows and the peak conveyance flows for the existing, short-term, mid-term and long-term conditions. The flows in Table 2-2 have been used for the conceptual sizing and costing of proposed wastewater system components.

TABLE 2-1: PEAKING FACTORS FOR MIMIMUM AND MAXIMUM FLOW CONDITIONS

Ratio to Annual Average	Sewage	Septage	Effluent Only
Minimum Day	0.40	0.50	0.50
Minimum Month	0.75	0.75	0.75
Annual Average	1.00	1.00	1.00
Maximum Month	1.25	1.50	1.25
Maximum 3-Day	2.4 to 2.7	1.75	1.25
Peak Instantaneous	4.0 to 4.6	1.75	1.25

TABLE 2-2: FLOWS USED IN ENGINEERING ASSESSMENT

Flows in gpd	Annual Average	Maximum 3-Day	Peak Conveyance
Existing	140,000	386,000	1,400,000
Short-Term	450,000	1,080,000	1,750,000
Mid-Term	1,690,000	3,030,000	4,240,000
Long-Term	3,350,000	5,520,000	7,350,000

Note: Refer to Appendix A for a breakdown of flows by category. Rounded to nearest 10,000 gpd.

2.3 IDENTIFICATION OF FUTURE WASTEWATER SYSTEM COMPONENTS

This section identifies the components of the future wastewater system to address future wastewater needs at shared facilities. The analysis and costs are presented in these categories.

2.3.1 Conveyance

Each community will have a collection system that transports flow to the location of the regional conveyance facilities. This report addresses the conveyance system costs but will not address the collection system costs.

2.3.2 Treatment

The JBCC WWTF will require upgrade/replacement to serve the regional needs. This report considers the costs for WWTF upgrade/replacement at the current WWTF location or at the former WWTF location (immediately adjacent to the current location). Any potential future WWTF expansions to include more regional flow and/or regional biosolids processing and/or regional source separated organics digestion is beyond the scope of this study.

2.3.3 Transport to Effluent Disposal

WWTF effluent is conveyed to the existing RIBs via the existing 11-mile long, 12-inch diameter forcemain. This report considers the costs for upgrades to this forcemain as well as supplemental forcemain(s) to the supplemental or replacement effluent disposal methods.

2.3.4 Effluent Disposal

The JBCC RIBs will need to be supplemented or replaced in order to serve the regional needs. This report considers the costs for additional RIBs as well as other supplemental/replacement effluent disposal methods.

2.4 CONVEYANCE

This section identifies the options for wastewater conveyance systems required to support shared wastewater management opportunities for Bourne, Falmouth, Mashpee, Sandwich and JBCC. The objectives of the conveyance study include the following:

- Identify alignments for conveyance of sewage from Bourne's southern section, Mashpee and Sandwich to JBCC WWTF for treatment and disposal;
- Identify alignments for conveyance of treated wastewater ("effluent") from the JBCC WWTF, the Bourne ISWM WWTF and the Falmouth BSR WWTF to the JBCC treated effluent conveyance system and disposal areas;
- Identify rehabilitation of sections of the JBCC gravity sewer system where shorter alignments and capital cost savings are available;

- Review conceptual profiles of each force main alignment to evaluate conceptual static and dynamic head on the pumping system;
- Develop preliminary hydraulic calculations to determine conceptual forcemain sizes; and
- Determine conceptual number and size of required pump stations.

2.4.1 Concept Design Criteria

The following key assumptions are used in this analysis:

- Elevation data were obtained from topographic information within Google Earth.
- Conceptual forcemain piping and wastewater lift station sizing are based on the conveyance flows in Table 2-2.
- Raw wastewater concept design criteria:
    - Peaking factor used for pump station flow: 4.0
    - Minimum force main velocity: 3 ft/s
    - Maximum force main design pressure: 275 ft (120 psi)
- Treated effluent concept design criteria:
    - Peaking factor used for pump station flow: 1.25
    - Minimum force main velocity: none
    - Maximum force main design pressure: 275 ft (120 psi)
- Force main materials:
    - Existing effluent force main: ductile iron
    - Proposed force mains: C900/C905 DR 18 PVC (235 psi) or HDPE (200 to 255 psi)
- Medium wastewater/effluent lift stations:
    - Flow: up to 1200 gpm
    - Pumps: wetwell installation, submersible, up to 75 hp
    - Generator and control panel in pump house
    - Conceptual construction cost: $1M each
- Large wastewater/effluent lift stations:

- Flow: 1200gpm or more
- Pumps: drywell installation, greater than 75 hp
- Generator and control panel in pump building over wetpit/drypit installation
- Conceptual construction cost: $2.5M each

- Conveyance routes utilizing existing JBCC gravity conveyance systems assume the rehabilitation of those sections through trenchless methods. Rehabilitation costs are assumed to be $150 per foot.
- Forcemain costs vary depending on the conditions of the route and are shown below in Table 2-3. A route within a public way with heavy traffic volumes or dense development has a higher cost than a route along routes with little traffic or adjacent development.

TABLE 2-3: FORCEMAIN COSTS PER FOOT

Forcemain Diameter	Route Characteristics		
	Public Way or Dense Development	Off Public Way or Less Dense	Within Railroad Right of Way
8-inch	$200	$120	$300
12-inch	$240	$160	$340
18-inch	$280	$200	$380

2.4.2 Summary of Preferred Conveyance Options

Multiple alternatives for each town were evaluated and the details of this evaluation are found in Appendix A. Current preferred conveyance routes are shown on Figure 2-1 and identified as follows:

- Bourne North (effluent) – Proposed lift station at ISWM WWTF connected to existing JBCC effluent forcemain, via a new 8" Bourne forcemain.
- Bourne South (sewage) – Proposed lift station at the intersection of Valley Bars and County Roads to JBCC WWTF via a new 12" Bourne forcemain and rehabilitated gravity sewer (shared with Sandwich).

- Falmouth (effluent) – Proposed lift station at BSR WWTF connected to the JBCC effluent forcemain(s) via a new 18-inch Falmouth forcemain in Routes 28 and 151.
- Mashpee (sewage) – Proposed lift station on Back Road Site 1 (Town lot) to JBCC WWTF via new 8" Mashpee forcemain.
- Sandwich (sewage) – Proposed lift station on portion of Lot-06-236 at 40 Route 130 to JBCC WWTF via Sandwich forcemain, and rehabilitated gravity sewers (shared with Bourne).

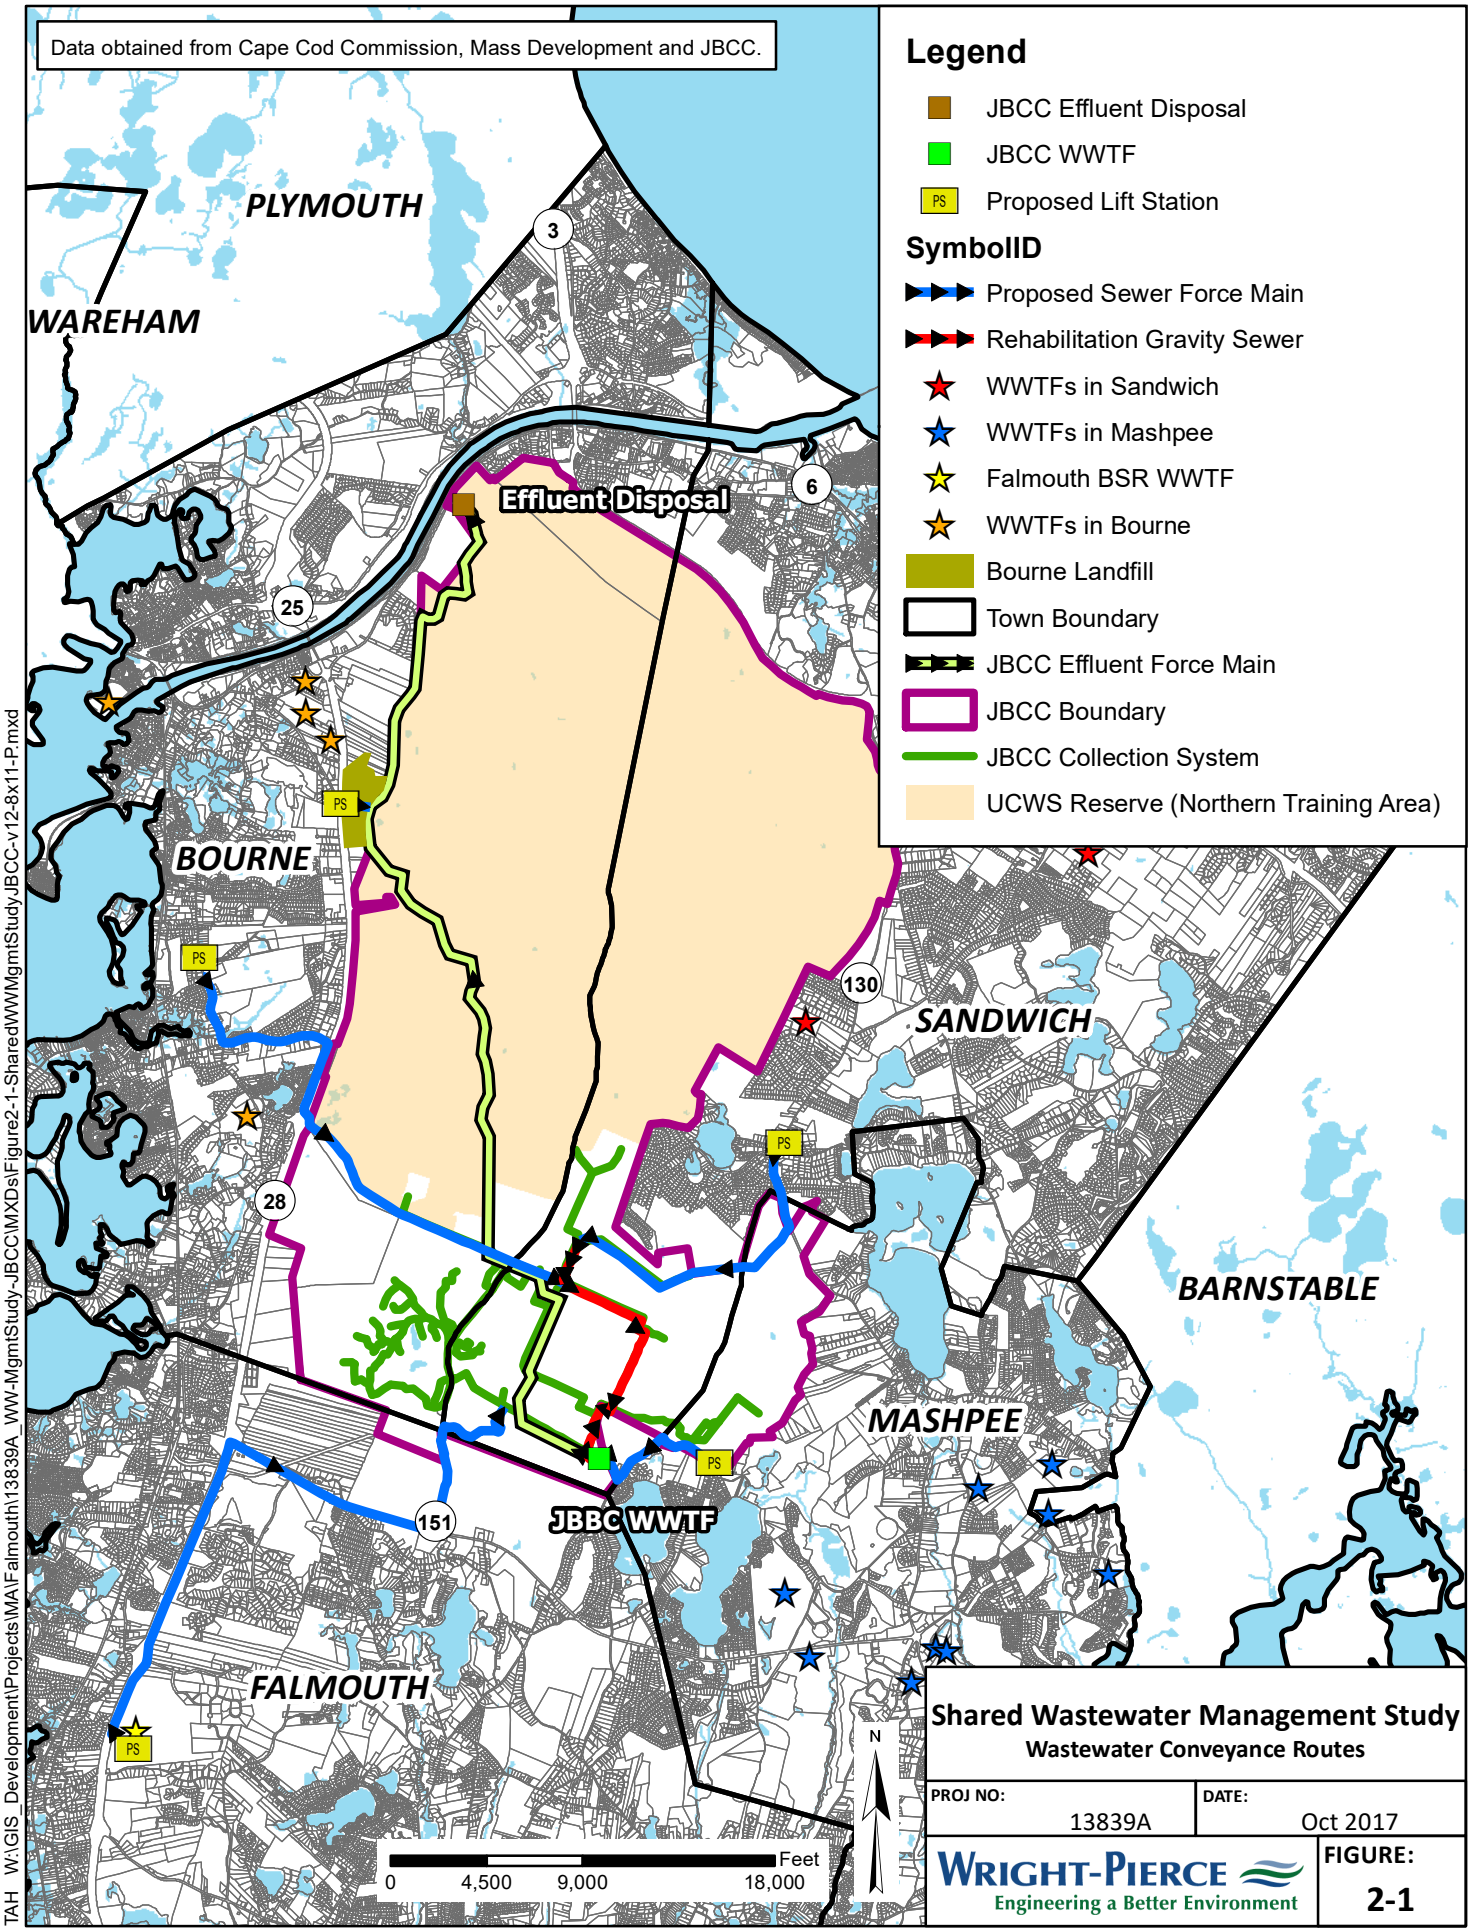
2.4.2.1 Preferred Bourne Alignment Details

One alignment was investigated for Bourne effluent flow from the ISWM WWTF to the JBCC effluent forcemain. We assumed the construction of a medium sized pump station to accommodate long-term conditions.

- 1 medium pump station, 570 gpm, 50 hp, velocity 1.7 fps
- 8" Forcemain, 100 feet

Option 1 was selected, which has the shortest route through the JBCC base, utilizing rehabilitated existing JBCC gravity sewer.

- 1 large pump station, 1250 gpm, 150 hp
- 12" Force main, velocity 3.6 fps, 5.1 miles
- JBCC rehabilitated gravity sewer, 2.3 miles
- Total route length: 7.4 miles
- Advantages - Least expensive (by $4.1M); shortest route by 2.1 miles; least amount in public ways and along dense development.
- Disadvantages - Uncertainty of obtaining construction easements within federal lands for forcemains; and uncertainty of the level of rehabilitation required for JBCC gravity sewers



Shared Wastewater Management Study

Wastewater Conveyance Routes

PROJ NO:	DATE:

WRIGHT-PIERCE
Engineering a Better Environment

FIGURE: 2-1

2.4.2.2 Preferred Falmouth Alignment Details

Option 1 was selected, which has the shortest route in public way.

- 1 Large Pump Station, 1300 gpm, 150 hp
- 18" Falmouth effluent forcemain, velocity 1.7 fps, 6.7 miles
- Total route length, 6.7 miles
- Advantages - Least expensive (by $0.1M).
- Disadvantages – Longer length in public way.
- Note: The route along the JBCC rail spur and right-of-way is approximately 1.4 miles shorter; however, the cost premium associated with constructing within the railroad right-of-way is significant. If Falmouth can negotiate fewer constraints than would typically be required by a railroad owner, then this shorter alignment may become less expensive and more favorable.

2.4.2.3 Preferred Mashpee Alignment Details

Option 1 was selected, which is the shortest route.

- Medium Pump Station, 560 gpm, 75 ft TDH, 20 hp
- 8" Mashpee forcemain, velocity 3.5 fps, 1.4 miles
- Total route length: 1.4 miles
- Advantages – Least expensive ($1.7M); shortest forcemain route by 3.4 miles
- Disadvantages – None identified.

2.4.2.4 Preferred Sandwich Alignment Details

Option 1 was selected, which has a shared rehabilitated gravity main with Bourne

- Large Pump Station, 1050 gpm, 40 hp
- 12" Dedicated Sandwich forcemain, velocity 3.0 fps, 2.9 miles
- JBCC rehabilitated gravity sewer, 0.4 miles (Sandwich) and 2.3 miles (shared with Bourne)
- Total route length: 5.6 miles
- Advantages - Least expensive- by $0.8M; shortest forcemain route by 0.9 miles
- Disadvantages - Uncertainty of obtaining construction easements within federal lands for forcemains; and uncertainty of the level of rehabilitation required for JBCC gravity sewers.

2.5 TREATMENT

This section identifies the treatment components of the future wastewater system, including the preliminary criteria used for sizing components. The primary factors which contribute to the selection of wastewater treatment processes are: wastewater flow and characteristics (domestic, commercial, industrial, septage, etc.); and effluent disposal method. Each of these factors is described below.

2.5.1 Wastewater Flow and Characteristics

The Upper Cape regional sewage treatment needs exceed the available capacity at the existing JBCC WWTF. As noted in Table 1-8, the targeted treatment capacity for sewage and septage flows are (annual average flow basis):

- Existing: 140,000 gpd
- Short-Term: 360,000 gpd
- Mid-Term: 760,000 gpd
- Long-Term: 1,200,000 gpd

The existing collection system serves the Cantonment, which includes domestic, food preparation and light industrial activities for the military population. The future collection system identified in Section 1 includes a higher volume of 'more conventional' sewage flows. The flow values above include 46,000 gpd of septage flow for mid-term and long-term. Septage is very concentrated and, in simplistic terms, has an 'equivalent load' of an additional 500,000 gpd of sewage and will result in higher cost for treatment on a 'per gallon basis'.

Given the order of magnitude increase in design flow, the existing treatment tank sizes and arrangement on the site will not be suitable for the necessary amount of expansion. Accordingly, we have assumed the WWTF will be replaced and will be constructed on the original WWTF site (i.e., adjacent to the current WWTF site). Portions of the existing WWTF will be rehabilitated for continued use, as described later in this section. There are many types of wastewater treatment processes which are applicable to this wastewater flow range (e.g., conventional activated sludge, sequencing batch reactors, oxidation ditches, membrane bioreactors, etc.); however, comparison

of the advantages/disadvantages and costs of the various type of wastewater treatment process is beyond the scope and objectives of this study. For the purposes of this report, sequencing batch reactor and membrane bioreactor activated sludge systems are considered.

2.5.2 Effluent Disposal Methods and WWTF Effluent Limits

The existing JBCC wastewater facilities have a Groundwater Discharge Permit (GWDP No 41-3) which is issued by the Department of Environmental Protection (DEP). The effluent limits imposed by DEP in GWDPs are common and well-established for rapid infiltration basins (RIBs) which do not discharge to watersheds of impaired waters or zones of contribution to drinking water wells (which is the case for the JBCC GWDP). Since the wastewater treatment and disposal needs defined herein are significantly greater than the existing GWDP, additional effluent disposal capacity will be needed. As noted in Table 1-8, the targeted effluent disposal capacity is 3,350,000 gpd (annual average flow basis).

This additional capacity will come in the form of additional land-based discharge (regulated by DEP) and/ or surface water discharge (regulated by EPA with input from DEP). The effluent disposal methods that were identified for consideration in this evaluation consist of: rapid infiltration; wicks; deep well injection; spray irrigation; effluent reuse; and outfall to surface water. The effluent disposal methods that were selected for more detailed evaluation consist of: rapid infiltration; wicks; deep well injection; and outfall to surface water. Each of these methods and the justification for keeping/eliminating methods is described in Section 2.7.

The anticipated WWTF effluent limits for each of the effluent disposal methods are presented in **Table 2-4**. The contents of this table should be reviewed with state and federal regulators at the appropriate time.

TABLE 2-4 ANTICIPATED MONTHLY AVERAGE WWTF EFFLUENT PERMIT LIMITS AND ASSOCIATED TREATMENT PROCESSES

Parameter	Rapid Infiltration	Wicks	Deep Well Injection	Outfall (Class SB)
Current				
BOD_5, mg/l	30	30	10	30
TSS, mg/l	30	30	5	30
Total Nitrogen, mg/l	10	10	5	5 (2)
Nitrate-Nitrogen, mg/l	10	10	5	n/a
Ammonia-Nitrogen, mg/l	n/a	n/a	n/a	n/a(4)
Oil & Grease, mg/l	15	15	n/a	n/a
Fecal Coliform, #/100 ml	200	200	14	88
Enterococci, #/100 ml	n/a	n/a	n/a	104
Total Residual Chorine, mg/l	n/a	n/a (1)	n/a (1)	n/a (3)
Total Recoverable Metals, mg/l	n/a	n/a	n/a	n/a (4)
Total Organic Carbon, mg/l	n/a	n/a	1	n/a
Turbidity, NTU	n/a	n/a	2	n/a
Virus Removal, log removal	n/a	n/a	5	n/a
Potential Future at Planning Horizon				
Total Phosphorus	unlikely	unlikely	unlikely	unlikely
Total Organic Carbon	unlikely	unlikely	applicable	unlikely
Unit Process				
Preliminary (Screening/Grit)	Yes	Yes	Yes	Yes
Primary	Yes	Yes	Yes	Yes
Conventional Nitrogen (TN <8 mg/l)	Yes	Yes	Yes	Yes
Enhanced Nitrogen (TN <5 mg/l)	No	No	Yes	Yes
Sand Filtration	No	Yes	No	No
Reverse Osmosis	No	No	Yes	No
Advanced Oxidation	No	No	Yes	No
Disinfection (Ultraviolet Light)	Yes	Yes	Yes	Yes
Chlorine Residual	No	Yes	Yes	No

Notes:

1.) Recommended for biofouling control. DEP would likely limit the chlorine residual to 4 mg/l.
2.) Presumed based on other surface water discharges in Massachusetts in southeast region.
3.) Use ultraviolet disinfection.
4.) Assume dilution factors of greater than 30:1 can be obtained which would preclude the need for metals or other toxics limits. Ammonia limits not needed since TN limit governs.

2.5.3 Concept Design Criteria

Treatment processes were selected to achieve the WWTF effluent limits associated with each effluent disposal method. These treatment processes are also summarized in Table 2-4. For example, in order to achieve the criteria for wicks, the new WWTF would need to include preliminary, primary, conventional nitrogen removal, sand filtration, disinfection and chlorine residual unit processes.

2.5.3.1 Existing WWTF

The existing WWTF will require some limited upgrades in the short-term in order to maintain reliability. These items were identified in the JBCC Water and Wastewater System Evaluation report (Wright-Pierce, 2014, Alternative 1A) and were summarized in Section 1.4.8 of this report. Once the new WWTF is constructed, the existing WWTF buildings and tankage will be upgraded and repurposed for continued use as administrative facilities, laboratory, shop, garages and septage receiving facilities.

2.5.3.2 Enhanced Nitrogen Removal/Sequencing Batch Reactor

The new WWTF will consist of an enhanced nitrogen removal (ENR) activated sludge treatment system targeting less than 5-mg/l effluent total nitrogen using a sequencing batch reactor (SBR) for the RIB, Wick and Canal Outfall disposal scenarios. The new WWTF will include the following additional items:

- Headworks Building (preliminary treatment).
- Process Building, to include process equipment (e.g., pumps, blowers, etc.), control room, sludge thickening/dewatering activities.
- Exterior primary treatment, SBR, sludge storage, and disinfection tankage.
- Odor control facilities.
- Standby power generator.
- Effluent pump station.

2.5.3.3 Enhanced Nitrogen Removal/ Membrane Bioreactor

The new WWTF will consist of an ENR activated sludge treatment system targeting less than 5-mg/l effluent total nitrogen using a membrane bioreactor (MBR) for the Deep Well Injection disposal scenarios. The new WWTF will include all the same elements as the ENR/SBR facility except that the MBR activated sludge tankage will also be enclosed in a building.

2.5.3.4 Sand Filtration

Conventional sand filtration will be included for the Wick effluent disposal option in order to keep the effluent total suspended solids well below the target criteria. The sand filtration system and appurtenant equipment will be located in a building.

2.5.3.5 Reverse Osmosis/ Advanced Oxidation

As noted in Section 2.7.3, reverse osmosis (RO) treatment will be used as the supplemental treatment method required to achieve the effluent limits specified for Deep Well Injection. It is presumed that Falmouth and Bourne effluent would not meet the necessary effluent limits for DWI without supplemental treatment, the ENR/MBR process will need to be sized for the full effluent disposal flow rate (depending on which composite scenario is applicable). In addition, RO produces reject water at approximately 10% to 20% of forward flow. For the purposes of this report, a reject rate of 15% has been utilized. This reject water has high concentrations of nutrients and organics and may have high concentrations of minerals (e.g., calcium, magnesium, sulfates, chlorides, etc.). This reject water will be recycled through the WWTF; accordingly, the WWTF needs to be upsized in order to treat the reject water. A reject water equalization storage tank, sized at 1 day of reject flow volume, is included in order to minimize any peaks or shock loadings. The reject water will also be treated via advanced oxidation to further breakdown TOC compounds prior to recycling through the WWTF.

An effluent storage tank will also be included for the purpose of storing effluent that does meet the criteria for DWI. This tank will be sized for 1 day effluent flow (3.3Mgal) to allow for the process to be remedied. Any liquid pumped to this tank will be disposed of via the RIBs or will be re-treated through the WWTF.

2.6 TRANSPORT TO EFFLUENT DISPOSAL

The concept design criteria for the effluent disposal piping are the same as was defined in Section 2.4.1 above. The following phased implementation approach was used for the transport to effluent disposal.

- Short term
    - Connect Bourne ISWM WWTF (effluent) to existing forcemain.
    - Connect Mashpee (sewage) to the JBCC collection system.
    - Continue to operate existing effluent pump station and existing effluent forcemains.
- Mid-term
    - Add additional flow from Bourne ISWM WWTF (effluent) and Mashpee (sewage)
    - Connect Falmouth BSR WWTF (effluent) to the JBCC effluent forcemains.
    - Connect Bourne-South (sewage) and Sandwich (sewage) to the JBCC collection system. Flow addition via septage from all communities as well.
    - Construct new 18-inch force main and valving interconnection with existing 12-inch force main.
    - Operate new effluent pump station and existing/new effluent forcemains.
- Long-term
    - Add additional flow from Bourne ISWM WWTF (effluent), Bourne-South (sewage), Falmouth BSR WWTF (effluent), and Sandwich (sewage).
    - Construct new 18-inch forcemain and valving interconnection with existing 12-inch and existing 18-inch forcemain.

2.7 EFFLUENT DISPOSAL

This section identifies the effluent disposal components of the future wastewater system, including the preliminary criteria used for sizing components. As noted above, the projected annual average effluent flows are 3,350,000-gpd. The needed additional capacity will come in the form of additional land-based discharge (regulated by DEP and in some cases by EPA as well) and/ or surface water discharge (regulated by EPA with input from DEP). The following effluent disposal methods are considered most applicable for this WWTF:

- Rapid infiltration
- Wicks
- Deep well injection
- Spray irrigation
- Effluent reuse
- Outfall to surface water

Subsurface leaching was not considered due to the relatively low application rates and relatively large land area requirement. A brief description of each effluent disposal method is presented below to provide context for the implications on the treatment unit processes required at the WWTF presented in Section 2.5 of this report. The locations of existing Zone II water supply protection areas and current/former contamination plumes are shown on Figure 2-2. The locations of MEP watersheds and TMDL status of each watershed are shown on Figure 2-3.

2.7.1 Rapid Infiltration

Rapid infiltration, also referred to as open sand beds or rapid infiltration basins (RIBs), can operate at high loading rates on sites with good permeability and significant depth to groundwater. Year-round application is routine. The reduced footprint compared with subsurface disposal often outweighs the drawback that the selected site can only be used for effluent disposal and that the effluent must be disinfected. A smaller disposal footprint also broadens the number of parcels that can be used as effluent disposal sites. Rapid infiltration systems require fencing around the perimeter to keep out wildlife and humans. The maintenance of the system includes periodic solids removal from the application surface (scarifying) and infrequent weeding. Rapid infiltration beds are considered less aesthetically pleasing than other alternatives and may not be recommended in densely populated areas.

2.7.1.1 Re-Rating Existing RIBs

In order to maximize the capacity of the existing RIBs, the following upgrades are recommended:

- Changing the GWDP to allow the 840,000 gpd value to represent the "Maximum 3-Day Peak Flow, moving average" instead of the current "Maximum Day";
- Segmenting the RIBs such that the site functions as 8 RIBs vs the existing 4 RIBs (which would allow the reserve area to represent 12% of the total infiltrative surface instead of the existing 25% of the total infiltrative surface); and
- Increasing the permitted loaded rate of the RIBs from 4.37 gpd/sf to a significantly higher rate (assumed to be 7 gpd/sf for this analysis) through large-scale loading tests, coordinated and approved with DEP.

In combination, these re-rating measures are anticipated to increase the permitted capacity from 840,000 gpd to 1,550,000 gpd. These items will need to be closely coordinated with DEP.

2.7.1.2 Sizing of New RIBs

For the purposes of this report, rapid infiltration at or near the existing RIB site will be sized based on 7 gpd/sf and will require a total site footprint based on 2 times the calculated infiltration area (3-day max flow basis) to account for site buffers/setbacks, roadways, etc. We have assumed the subsurface conditions in the immediate vicinity of the existing RIB site will have similar hydrogeologic properties and that the resulting groundwater mounds will be consistent with the existing groundwater mound.

2.7.2 Wicks

A wick is a vertical cylinder of highly permeable material that provides an efficient path for effluent to travel from the surface point of discharge to the soil in the vadose (unsaturated) zone. Effluent from a wick receives soil aquifer treatment (SAT) through the vadose zone. Wicks allow for very high loading rates on a small footprint because they disperse effluent both horizontally and vertically. Another advantage to wicks is the ability to bypass less permeable material. Wicks are not very intrusive. The only above-grade components include an access vault and cover.

This technology is relatively new and therefore DEP has stringent permitting requirements. First, the design must include standby wicks to provide more than 100 percent redundant disposal capacity, so that if a wick were to fail or be overloaded, another wick can be brought on-line immediately. Second, there must be another permitted disposal location that could be developed with a traditional system if the wicks fail prematurely. Extensive hydrogeologic evaluations are required to determine the suitability of the soil for wicks. WWTF effluent must be filtered to maintain a total suspended solids concentration of 5 mg/l or less. The use of chlorine to manage biofouling have the potential to create trihalomethanes (THMs) in groundwater due to elevated background concentrations of chloroform in the groundwater on Cape Cod. This should be considered in permitting/design.

This technology has been permitted at three locations in Massachusetts (i.e., Hingham, Tisbury and West Island in Fairhaven) and is being considered for implementation in at least one other location in Massachusetts (i.e., Orleans). For the purposes of this report, each wick will be sized to handled 100,000 gpd of effluent (3-day max flow basis).

2.7.3 Deep Well Injection

Deep well injection (DWI) involves a special-purpose well designed for the disposal of effluent into the groundwater in the saturated zone. The groundwater in the Upper Cape is designated as a Sole Source Aquifer (Sagamore Lens). DWI would be regulated by the DEP under the Groundwater Discharge regulations (314 CMR 5.00) and by the EPA under the Underground Injection Control (UIC) program and the Sole Source Aquifer (SSA) program. As of the date of this report, "aquifer storage and recovery" (ASR) and indirect potable water reuse have been implemented in water-strained areas of the United States (e.g., California, Florida, Arizona). There are no full-scale DWI applications for effluent disposal in Massachusetts at this time; however, there are numerous groundwater treatment systems on JBCC that use a pump/treat/disposal approach similar to DWI. A DWI pilot test was conducted at the Hyannis WPCF in 2003 (*Pilot Test for Using Injection Wells for Reclaiming Treated Municipal Wastewater, Town of Barnstable, MA*, Stearn & Wheler, 2003). The pilot test report recommended filtration (<10 micron, to prevent fouling), maintaining a chlorine residual (to prevent biofouling), and additional pilot-scale and full-scale testing prior to further consideration of use on Cape Cod. DWI will have similar concerns regarding potential THM formation as wicks. This should be considered in permitting/design.

Based on the requirements outlined in 314 CMR 5.10, the treatment limits summarized below are applicable for discharge within a Zone II, for a discharge within a Zone II and with less than a 2-year travel time to a water supply well, and for any groundwater discharge "without the benefit of treatment in the unsaturated zone".

	Column A Within Zone II (4A-a)	Column B Within Zone II and Less than 2-Year Travel Time (4A-c,d)	Column C Any GW Discharge without Treatment in Unsaturated Zone (5.10.4C)
TSS	<10 mg/l	<5 mg/l	<5 mg/l
Turbidity	<5 NTU	<2 NTU	<2 NTU
TOC	<3 mg/l	<1 mg/l	<1 mg/l
Total Nitrogen and Nitrate-Nitrogen	<10 mg/l	<5 mg/l	<5 mg/l
Fecal Coliform	<200/ 100ml	<14/ 100ml	<14/ 100ml
Viruses	n/a	>5 log removal	>5 log removal

The primary regulatory focus for deep well injection applications is the impact on drinking water (i.e., TOC, fecal coliform and virus removal). As noted in the table above, there is no difference in the effluent limits between Column B and Column C. This means that the regulations provide no relief in treatment standards for the DWI approach even if located remote from water supply wells.

In order to achieve the criteria for discharge within a Zone II and less than a 2-year travel time to a water supply well (Column B) or for any discharge "without the benefit of treatment in the unsaturated zone" (Column C), a reverse osmosis (RO) treatment system will be required primarily related to the TOC limits of <1 mg/l. For the purposes of this report, the approach is to inject highly treated effluent into the Sole Source Aquifer very deep in the aquifer (i.e., between approximately EL -100 to EL -200, or approximately 300 feet below ground surface) and substantially below the lowest elevation of the deepest drinking water supply wells. The typical screened interval in the Bourne and Falmouth water supply wells is EL 5.0 to EL -46.6 (USGS, SIR-2004-5181, Table 1-3). The premise is that water is returned to the local hydrologic cycle by replenishing the water levels in the Sagamore Lens at the bottom of the aquifer. At this depth, it is presumed that all DWI effluent will emerge beyond all nitrogen sensitive embayments/watersheds. The DWI will not include any concentrated reject water. For the purposes of this report, each DWI well is assumed to convey 750,000 gpd effluent flow (3-day max flow basis).

If the criteria for discharge within a Zone II (Column A) were applicable, a granular activated carbon (GAC) filtration system would likely be sufficient primarily based on its presumed ability to achieve <3 mg/l TOC. A GAC filtration system would be much less costly and less complicated to operate than the other treatment options and may be sufficiently conservative for permitting, given the following considerations:

- Much of the water to be disposed of via DWI already recharges the Sagamore Lens in a decentralized manner through individual septic systems.
- The DWI effluent would be treated to a substantially higher level than the existing decentralized treatment levels.
- The proposed DWI volume represents an estimated 1.7% of the annual average precipitation recharge to the Sagamore Lens with an assumed 3.35-mgd DWI recharge and an estimated 190-mgd annual average precipitation recharge (USGS, 2000).
- The DWI effluent would be injected approximately 50 to 100 feet below the bottom of the deepest drinking water well in the Sagamore Lens.

2.7.4 Spray Irrigation

Landscape spray irrigation is an example of technology that can be used at site with a dual use (e.g., effluent can be applied to parks, sports fields, golf courses, or landscaping. All of these activities are associated with human activity and require meeting the effluent reuse guidelines (DEP reclaimed water regulations and US EPA Reclaimed Water Guidelines), which usually adds to the cost of wastewater treatment. Irrigation is certainly restricted to seasonal operation which requires either winter storage or a complementary effluent disposal system. This technique uses moderate application rates.

Based on an assumed application rate of 1.5 inches of wastewater per week and an assumed total site area at 1.5 times the area required for spray fields to account for site buffers/setbacks, roadways, etc. The mid-term site area needs are 55 acres total and the long-term site area needs are 146 acres total. Based on the presumption that this amount of land would likely need to be within in the UCWS Reserve/ Northern Training area and would likely be in or around existing Zone II water supply protection areas and existing contamination plumes, this approach is determined to be not viable.

2.7.5 Effluent Reuse

DEP uses the term "reclaimed water" which it defines as wastewater that has been treated at a wastewater treatment facility to an advanced degree and used again for various applications. The fundamental premise behind effluent reuse is the recognition of the value of water and the nutrients it may carry, tempered by the public health aspects of public contact with wastewater-derived material.

A good way to contrast "effluent disposal" and "use of reclaimed water" is to consider spray irrigation. A spray irrigation site that receives typical treatment plant effluent must include fencing or other means of preventing public access, as well as significant vegetated buffers to control spray drift (i.e., effluent disposal). If a higher level of treatment is provided, DEP allows for spray irrigation on golf courses where the public has access (i.e., reclaimed water).

The artificial recharging of aquifers is only permitted in watershed basins and sub-basins which are stressed water resource areas where it is necessary to replenish stream flow, enhance the productivity and capacity of an aquifer, and/or improve upon or mitigate water quality problems. The water quality criteria for the treated wastewater are extremely rigorous, requiring that reclaimed water be virtually pathogen and contaminant free, and are dependent on which “class” of effluent reuse is proposed. Based on the requirements outlined in 314 CMR 20.17, the treatment limits summarized below are applicable for the various classes of reclaimed water use.

	Class A Reuse	Class B Reuse	Class C Reuse
BOD_5, mg/l	10	30	30
TSS, mg/l	5	10	30
Total Nitrogen, mg/l	-	-	-
Nitrate-Nitrogen, mg/l	10	10	10
Turbidity, NTU Average Maximum	 2 10	 - -	 - -
Fecal Coliform, #/100ml Median Maximum	 0 14	 14 100	 0 200
Potential Uses	<u>Public contact</u> Irrigation Toilet flushing Agriculture Industrial use Car washes Fire protection Recreational Impoundments	<u>No public contact likely</u> Irrigation Concrete mix Aggregate washing Street cleaning	<u>No public contact</u> Irrigation of non-edibles Industrial use

The primary regulatory focus for effluent reuse applications is the impact on human health from incidental contact (i.e., fecal coliform). The effluent limits for effluent reuse are less stringent than for deep well injection with the exception of fecal coliform, which is substantially more stringent.

There are a number of potential effluent reuse applications at JBCC, including golf course irrigation, vehicle washing, toilet flushing and fire protection. Each of these potential uses is intermittent and will not represent a disposal source for all or even a large portion of the effluent flow. Accordingly, this approach is considered viable but only as a supplemental method in the future. This approach has not been incorporated into the cost analysis.

2.7.6 Outfall to Surface Water

A new effluent discharge to surface water in Massachusetts must meet the requirements of Massachusetts Ocean Sanctuaries Act MGL Ch.132A, Sec.16G (OSA). The OSA requires that the following 10 items must be met (*italics indicate text from MGL*):

1) *The new or modified discharge shall be consistent with the intent and purpose of the act. Any discharge shall meet the water quality standards of the receiving water body and the standards of the act to protect the appearance, ecology and marine resources of the waters of the sanctuary.*
2) *The new or modified discharge shall meet the United States Environmental Protection Agency's approved TMDL, if any, on the receiving water body.*
3) *The applicant shall have adopted and implemented a plan approved by the department requiring the pretreatment of all commercial and industrial wastes discharged to the POTW.*
4) *The applicant shall have adopted and implemented a program for water conservation according to the guidelines established by the water resources commission.*
5) *The applicant shall have adopted and implemented a plan, approved by the department, to control and minimize inflow and infiltration.*
6) *The applicant shall have adopted and implemented a plan, approved by the department, to control any combined sewer overflows.*
7) *The new or modified discharge shall not significantly affect the quality or quantity of existing or proposed water supplies by reducing ground or surface water replenishment.*
8) *The new or modified discharge is consistent with the policies and plans of the Massachusetts coastal zone management program.*
9) *The new or modified discharge and treatment plans are consistent with all applicable federal, state and local laws, ordinances, by-laws, rules and regulations protecting the environment, including but not limited to, the requirements of chapters 21, 91, 130 and 131.*
10) *The proposed discharge and outfall structure will not adversely impact marine fisheries or interfere with fishing grounds or the normal operation of fishing vessels.*

If the above can be met, then a surface water discharge could be permitted by DEP and EPA. The JBCC effluent discharge would need to meet standards set forth in state and federal water quality legislation. These standards establish minimum effluent discharge requirements which must be satisfied at all times. In accordance with Section 402 of the Clean Water Act, the WWTF's effluent quality requirements would be stipulated in a National Pollutant Discharge Elimination System (NPDES) permit which would be issued by the EPA. For the purposes of this report, we have presumed that a permit for surface water discharge to the Cape Cod Canal, which is designated as

a Class SB waterway by the Massachusetts DEP (SWQ Standards) and is not designated as an Outstanding Resource Water or an Area of Critical Environmental Concern, can be obtained.

MADEP Implementation Policy for Mixing Zone (January 1993) defines how a mixing zone is established for a surface water outfall. A "mixing zone" is an area or volume of a waterbody in the immediate vicinity of a discharge where the initial dilution of the discharge occurs. Within a mixing zone, excursions from certain water quality criteria may be tolerable, provided this does not interfere with the existing or designated uses of the segment. Water quality criteria apply at the boundary of the mixing zone. The mixing zone is a function of the proposed outfall flow rate versus the minimum flow of the receiving water. In the case where there is tidal flow, there is a significant amount of judgement used by the permit writer in calculating the appropriate dilution factor and sizing the mixing zone. The following physical parameters were used in our evaluation:

- Minimum channel width at the channel bottom of 450 feet.
- Minimum channel width at the water surface of 670 feet.
- Minimum water depth of 32 feet.
- Estimated westward flow of 22,000 Mgal per tide cycle and an estimated eastward flow of 19,000 Mgal per tide cycle, with a net 8,500 Mgal per tide cycle to the west (Sandwich Draft Environmental Impact Statement, 1981).
- Canal water velocity between 3 to 5 fps between high and low tide and a minimum net velocity of 0.1 fps at slack tide.
- Depth of water over diffusers of 30 feet, minimum.
- The use of multi-port diffusers oriented perpendicular to receiving water flow, with a discharge velocity of approximately 10 fps per port, in order to maximize dispersion and mixing of effluent with the receiving water.

In the case of a simple single-directional flow (i.e., river), the dilution factor is calculated by the formula: (River flow + WWTF flow) / WWTF flow. On this basis, the estimated dilution factor

would be 2,500:1 for an effluent flow of 3.50 mgd and a receiving water flow of 8,500 mgd. However, given that this application would be for tidal, dual-directional flow, the simple dilution factor is not applicable. Based on our experience with tidal outfalls, we anticipate that it will be possible to achieve a dilution factor of at least 30:1 with an overall diffuser length of 50 to 60 feet. We recommend a minimum dilution factor of 20:1 in order to avoid the toxics criteria. Given that the Canal is a heavily used commercial shipping channel, heavily used recreational fishing location and has a strong current, construction and maintenance of an outfall will be expensive.

It is important to note the following considerations related to a surface water outfall:

- Site-specific data collection and modelling will be required in order to determine actual dilution factor at this location.
- Long-term water quality monitoring will be needed to establish existing conditions in order for MADEP to make an anti-degradation determination.
- A "parallel to shore diffuser" or a "sidebank outfall" would be preferred based on the existing uses of the Canal and the construction/maintenance aspects of this application
- Numerous other factors go into siting and permitting a surface water outfall, including evaluation of existing water quality, completion of an anti-degredation review, and evaluation of existing uses (including human uses and aquatic life uses).
- The application and review process for a new surface water discharges should be expected to take a minimum of 3 to 5 years and the successful conclusion is not assured.

2.7.7 Summary of Land-Based Effluent Disposal Alternatives

The hydrogeologic aspects of the effluent disposal options have been reviewed by GeoHydroCycle (GHC). GHC's analysis is presented in Appendix B and summarized here.

2.7.7.1 Rapid Infiltration Beds

The existing 4 RIBs, once upgraded and loaded at the projected 1.55-mgd rate, will produce a groundwater mound of approximately 10 to 15 feet above the seasonal high water table. That mound is expected to dissipate in a down-gradient direction sufficiently to prevent any breakout

of effluent-impacted groundwater. All of the effluent-impacted groundwater will emerge in the Cape Cod Canal over several hundred feet of its length, without impacting drinking water wells.

A set of 4 new RIBs located immediately west of the existing RIBs is expected to exhibit similar mound heights when those RIBs are loaded with the medium-term flow of 1.55 mgd. While there may be some superposition of the mounds of the existing and new RIBs, the additional mound is relatively minor compared to the significant unsaturated zone at this location. No break-out or well impacts are expected.

The set of 6 new RIBs needed for the long-term flows (an additional 2.4 mgd) is expected to behave similarly to the existing and medium-term RIBs since they would be loaded at the same surficial rate in a similar geologic setting.

2.7.7.2 Wicks

Wicks are a relatively new disposal technology for Massachusetts. The significant depth to water table and glacial outwash soils at JBCC provide the conditions were wicks can be successful. Wicks would best be located outside of nitrogen-sensitive watersheds and downgradient from water supply wells. The location, design and capacity of wicks can only be determined through large-scale testing.

2.7.7.3 Deep Well Injection

Deep injection wells could be located in an area near the military cemetery at the southwest corner of JBCC and near the existing WWTF at the southeast corner of JBCC. There are no existing contaminant plumes or Zone IIs in either location. With screens located near bedrock, the injection wells would discharge approximately 100 feet to 150 feet below the intake screens at the deepest water supply wells. The near-bedrock discharges would allow the effluent-impacted groundwater to emerge in Buzzards Bay (westerly injection wells) or in Nantucket Sound (easterly injection wells), with little or no expected impact on coastal embayments. The travel time from the injection wells to the point of emergence is expected to be 2 or more decades.

Injection wells are a new technology for Cape Cod and the location, design and capacity of the wells would be determined only through large-scale testing. The ability to bypass coastal embayments would need to be further demonstrated through detailed groundwater modeling.

2.8 IDENTIFICATION OF COMPOSITE ALTERNATIVES

This section identifies and describes the following alternatives for the treatment and disposal aspects of the future wastewater system:

1) New WWTF with RIBs
2) New WWTF with RIBs and Wicks
3) New WWTF with RIBs and Deep Well Injection
4) New WWTF with RIBs and Canal Outfall
5) New WWTF with Deep Well Injection
6) New WWTF with Canal Outfall

As described previously, the above disposal methods were determined to be the most appropriate. Spray irrigation was determined to be not feasible at this scale and effluent reuse is possible but only as a supplemental disposal method. Treatment process schematics for each alternative are shown on Figure 2-4. Each of the alternatives includes limited upgrades to the existing JBCC wastewater facilities in order to maintain permit compliance and capacity in the short-term to mid-term. All flow rates indicated in Section 2.8 reference the 3-day peak flow. Each of the alternatives includes a description of the anticipated phasing requirements. A summary of the upgraded and new facilities for each of the composite alternatives is presented on the following pages. The project phasing and management entity boundaries which are included in the planning-level cost estimates are shown on Figure 2-5.

2.8.1 New WWTF with RIBs

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/SBR WWTF plus disinfection. • 4 new RIBs on the adjacent US Government parcel (ACOE) to achieve an additional 1.55-mgd capacity. • 1 new effluent forcemain (11.0 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • 6 new RIBs on the adjacent US Government parcel (ACOE) to achieve an additional 2.42-mgd capacity. • 1 new effluent forcemain (11.0 miles) located parallel to existing (3 total forcemains).

2.8.2 New WWTF with RIBs and Wicks

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/SBR WWTF plus sand filtration and disinfection. • Assume that Bourne ISWM WWTF and Falmouth BSR WWTF can meet the effluent TSS and turbidity requirements for wicks (i.e., no cost included herein). • 16 new wicks to achieve an additional 1.55-mgd capacity. • 1 new effluent forcemain (11.0 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • 25 new wicks to achieve an additional 2.42-mgd capacity. • 1 new effluent forcemain (11.0 miles) located parallel to existing (3 total forcemains).

2.8.3 New WWTF with RIBs and Deep Well Injection

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/MBR WWTF plus RO/Storage and disinfection. • 3 new DWI wells in the Cantonment to achieve an additional 1.55-mgd capacity. • Add RIBs or wicks to serve as reserve disposal (1.55 mgd) • 1 new effluent forcemain (2.3 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • 4 new DWI wells in the Cantonment to achieve an additional 2.42-mgd capacity. • 1 new effluent forcemain (2.3 miles) located parallel to existing (3 total forcemains).

2.8.4 New WWTF with RIBs and Canal Outfall

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/SBR WWTF plus disinfection. • Assume that Falmouth BSR WWTF and Bourne ISWM WWTF can meet the effluent requirements for a Canal outfall (i.e., no cost included herein). • New Canal outfall sized for an additional 3.97-mgd capacity. • New effluent forcemain (11.5 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • New effluent forcemain (11.5 miles) located parallel to existing (3 total forcemains).

2.8.5 New WWTF with Deep Well Injection

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Maintain existing RIBs to serve as reserve disposal. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/MBR WWTF plus RO/Storage and disinfection. All Falmouth and Bourne effluent flow brought to JBCC WWTF site. • 6 new DWI wells in the Cantonment to achieve an additional 3.10-mgd capacity. • 1 new effluent forcemain (2.3 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • 4 new DWI wells in the Cantonment to achieve an additional 2.42-mgd capacity. • 1 new effluent forcemain (2.3 miles) located parallel to existing (3 total forcemains).

2.8.6 New WWTF with Canal Outfall

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Maintain existing RIBs to serve as reserve disposal. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Mid-Term: • New ENR/SBR WWTF plus UV disinfection. • Assume that Bourne ISWM WWTF and Falmouth BSR WWTF can meet the effluent requirements for a Canal outfall (i.e., no cost included herein). • New Canal outfall sized for an additional 5.52-mgd capacity. • New effluent forcemain (11.5 miles) located parallel to existing. • Connect Falmouth BSR WWTF (effluent), Bourne and Sandwich (sewage)
Long-Term: • New effluent forcemain (11.5 miles) located parallel to existing (3 total forcemains).

2.9 EVALUATION OF COMPOSITE ALTERNATIVES

This section evaluates the composite alternatives for the future wastewater system for cost and non-cost factors. Planning-level cost estimates for the long-term flows are summarized in Table 2-5. Planning-level cost estimates for the mid-term flows are summarized in Table 2-6

2.9.1 Planning-Level Capital Costs

Planning-level capital cost estimates were developed using cost estimating procedures consistent with industry standards utilizing concept layouts, unit cost information, and planning-level cost curves, as necessary. The capital costs include the following key components: wastewater collection, transport-to-treatment, wastewater treatment, transport-to-disposal, effluent disposal, land acquisition, and technical services and contingencies. Key technical data were compiled for all plans, based on conceptual designs. Next, typical "unit costs" were applied (e.g., dollars per foot of pipe, or dollars per pump station) using recent experience from publicly-bid wastewater projects across New England. Unit costs for “baseline” treatment and disposal facilities (i.e., ENR/SBR and disinfection) were taken from the Barnstable County Cost Report (“*Comparison of Costs for Wastewater Management Systems Applicable to Cape Cod*”, April 2010). Once basic construction costs were estimated, allowances were added for contingencies and technical services (40% of construction subtotal) and financing/legal/administration expenses (3% of construction subtotal). Land costs were excluded from this analysis. Backup information and additional assumptions are identified in Appendix A. The cost information presented herein is in current dollars and is based on ENR Index 10800. The planning-level capital costs for the long-term flows are summarized in Table 2-5 and indicate that:

- Option 1 (New WWTF with RIBs) is the alternative with the lowest capital cost
- Option 4 (New WWTF with RIB & Outfall) has the second lowest capital cost
- Option 2 (New WWTF with RIB & Wicks) has the third lowest capital

TABLE 2-5: SUMMARY OF PLANNING-LEVEL COST ESTIMATES AND COST ALLOCATION (BASED ON LONG-TERM CONSTRUCTED AS A SINGLE PROJECT)

Option	1	2	3	4	5	6
Description of Effluent Disposal	**RIB**	**RIB & Wicks**	**RIB & DWI**	**RIB & Outfall**	**DWI**	**Outfall**
Capital Cost						
Construction - Conveyance	$27,030,000	$27,030,000	$27,030,000	$27,030,000	$27,030,000	$27,030,000
Construction - Treatment	$38,900,000	$41,300,000	$66,100,000	$41,300,000	$72,700,000	$41,300,000
Construction - Transport to Disposal	$22,900,000	$22,900,000	$5,160,000	$23,950,000	$6,340,000	$23,950,000
Construction - Disposal	$9,500,000	$8,900,000	$11,700,000	$6,700,000	$12,900,000	$8,400,000
Contingency, Technical, Legal/Admin/Finance	$42,280,000	$43,060,000	$47,300,000	$42,560,000	$51,160,000	$43,290,000
Total Capital Cost	**$140,610,000**	**$143,190,000**	**$157,290,000**	**$141,540,000**	**$170,130,000**	**$143,970,000**
Ratio to Lowest - Total Capital Cost	1.00	1.02	1.12	1.01	1.21	1.02
Ratio to Lowest - Capital Cost, excl. Conveyance	1.00	1.03	1.16	1.01	1.29	1.03
Annual Operation & Maintenance Cost	**$2,110,000**	**$2,210,000**	**$5,230,000**	**$2,310,000**	**$6,490,000**	**$2,310,000**
Ratio to Lowest - Annual O&M	1.00	1.05	2.48	1.09	3.08	1.09
Total Annual Debt Service on Capital Cost	$8,600,000	$8,760,000	$9,620,000	$8,660,000	$10,400,000	$8,800,000
Total Equivalent Annual Cost (Note 3)	**$10,710,000**	**$10,970,000**	**$14,850,000**	**$10,970,000**	**$16,890,000**	**$11,110,000**
Ratio to Lowest - Equivalent Annual Cost	1.00	1.02	1.39	1.02	1.58	1.04
EAC per thousand gallons of disposal capacity	$8.76	$8.97	$12.14	$8.97	$13.81	$9.09

Notes:

1) Costs are presented in current dollars based on Engineering News Record Construction Cost Index 10800 (October 2017).
2) Refer to Appendix A for supporting information.
3) Equivalent Annual Cost equals Annual O&M Cost plus the Annual Debt Service on Capital Cost.
4) Allocation for Conveyance is 100% to each town. Allocation for treatment/transport/disposal is pro-rated based on flow capacity requested.
5) Blue indicates lowest cost option, green indicates second lowest cost option and orange indicates third lowest cost option.

2.9.2 Planning-Level Operation and Maintenance Costs

Annual operation and maintenance (O&M) costs were developed for each plan for the purposes of comparison among the plans. These planning-level O&M costs were developed using the anticipated wastewater flow rates for each plan. Unit O&M costs were taken from the Barnstable County Cost Report (April 2014). These O&M estimated include the following types of expenses: labor, including fringe benefits; electrical energy for powering pumps and treatment equipment; fuel for building heating and vehicular use; chemicals; disposal of dewatered sludge; laboratory testing and other permit compliance costs; administrative costs such as insurance; and equipment maintenance and replacement. The cost information presented herein is in current dollars and is based on ENR Index 10800. Backup information and additional assumptions are identified in Appendix A. The annual O&M costs for the long-term flows are summarized in Table 2-5 and indicate that:

- Option 1 (New WWTF with RIBs) is the alternative with the lowest annual O&M cost
- Option 2 (New WWTF with RIBs & Wicks) has the second lowest annual O&M cost
- Option 4 (New WWTF with RIBs & Outfall) has the third lowest annual O&M cost, tied with Option 6 (New WWTF with Outfall)

2.9.3 Equivalent Annual Cost

The “equivalent annual cost" (EAC) is a standard economic tool that allows for the calculation of a single "cost" to represent the combination of capital costs and annual expenses for O&M. The equivalent annual cost is the sum of the annual O&M cost plus the annualized debt service on the capital costs. For the purposes of this study, the present worth has been computed assuming a 2% interest rate and a 20-year loan based on presumed DEP CWSRF (Clean Water State Revolving Fund) loan financing. The equivalent annual costs for the long-term flows are summarized in Table 2-5 and indicate that:

- Option 1 (New WWTF with RIBs) is the alternative with the lowest equivalent annual cost
- Option 2 (New WWTF with RIBs & Wicks) has the second lowest equivalent annual cost tied with Option 4 (New WWTF with RIB & Outfall)
- Option 6 (New WWTF with Outfall) has the third lowest equivalent annual cost

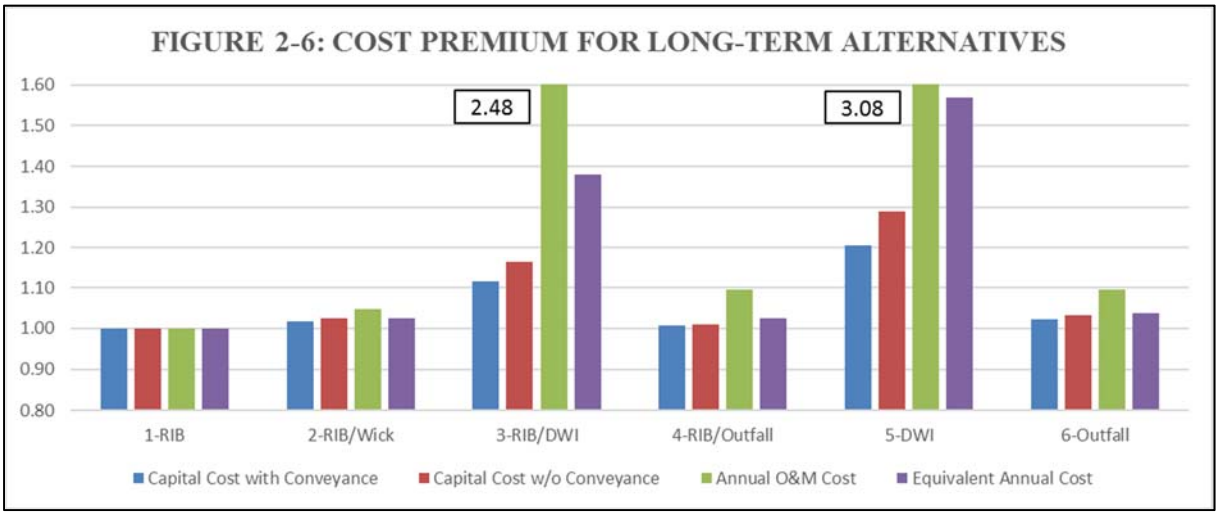
2.9.4 Considerations for Composite Alternatives

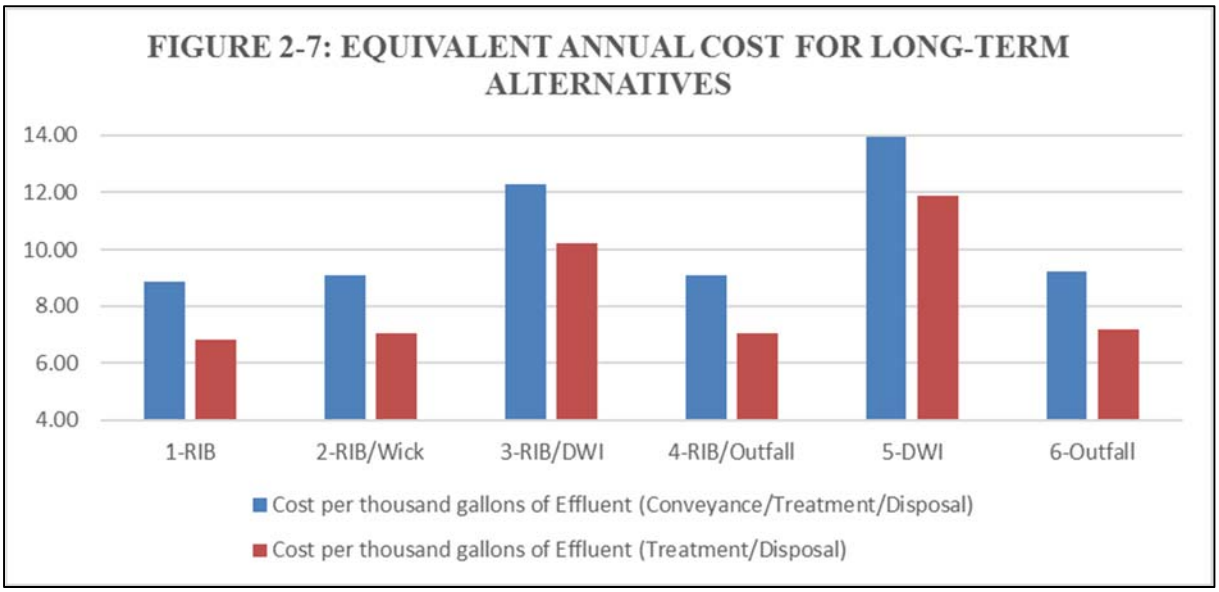
- This analysis represents a complex matrix of alternatives and considerations. There may be other combinations of composite alternatives which are determined to be of interest based on this analysis.
- Each alternative represents a scenario that requires a number of technical, political, permitting and logistical matters to fall into place.
- Laboratory testing should be conducted for a suite of primary and secondary drinking water parameters on the existing WWTF effluent in order to better assess implications to RO treatment throughput and reject water production.
- Pilot testing should be completed on WWTF effluent with potential MBR and RO treatment processes to better assess sizing implications for this project.
- Each alternative includes two new forcemains plus the existing forcemain to the disposal locations (i.e., 3 total forcemains). The reasons for this include increased operational flexibility and redundancy and decreased capital cost for mid-term phasing. This approach could be modified to reduce the long-term capital costs. For example, for Options 1, 2, 4, and 6, a single large effluent forcemain could be installed (i.e., 2 total forcemains) which would save approximately $16M but reduce piping redundancy and would increase the mid-term costs.
- The costs associated with "transport-to-disposal" are significant due to the distance from the WWTF site. Based on a review of Figure 2-2 (Zone II and Contamination Plumes) and Figure 2-3 (MEP Watersheds and TMDL Status), it does not appear that additional RIB sites or wick sites near the existing effluent forcemain would be feasible or recommended until the Canal South watershed is reached, which is approximately 60% of the distance to the existing RIB location and which is within the Reserve/Northern Training Area.
- By selecting disposal sites closer to the WWTF via the use of deep well injection, the transport-to-disposal cost is significantly reduced; however, this savings is more than offset by the additional cost and complexity of the treatment processes required.
- The deep well injection alternatives use RO treatment to achieve the stringent DEP standard related to TOC removal. It may be possible to implement a granular activated carbon (GAC) filtration process but it would likely require changes in the DEP regulations following a

detailed pilot testing protocol. A GAC filtration approach would lower the capital, annual O&M and equivalent annual cost for deep well injection.

- Assuming the towns have relatively few effluent disposal sites which are outside of nitrogen-sensitive MEP watersheds, then the use of the JBCC wastewater facilities will save the towns costs associated with additional sewering required to offset effluent disposal within a nitrogen sensitive area.
- Option 1 (New WWTF with RIBs) is the lowest cost alternative for long-term and mid-term conditions. The cost premium associated with Options 2, 4 and 6 are relatively small (i.e., less than 5%) for the long-term (refer to the "ratio rows" in Table 2-5). For this level of analysis, it is reasonable to consider Options 1, 2, 4, and 6 as equivalent from a cost perspective. Options 3 and 5 are considerably higher cost. The cost premiums are illustrated on Figure 2-6 below.
- A similar analysis was performed for the mid-term costs (refer to Appendix A). The results of the mid-term analysis show a similar ranking of alternatives for capital cost, annual O&M cost and equivalent annual cost. As would be expected, the capital cost, annual O&M cost and equivalent annual cost are lower for the mid-term; but the unit cost (EAC per thousand gallons of disposal capacity) is higher due to diseconomies of scale.
- Costs associated with phased implementation have not been considered. These costs will be considered for the recommended plan.
- It will be important for the participants to agree on whether to make selections and decisions based on the long-term cost or the mid-term.

FIGURE 2-6: COST PREMIUM FOR LONG-TERM ALTERNATIVES





2.9.5 Evaluative Criteria

This section of the report describes the evaluative criteria that were used for this project and resulting ratings. Each alternative was rated as "advantageous", "neutral" or "disadvantageous" for each of the evaluative criteria. Each criterion and the basis for the rating is summarized below.

- Capital cost: This is an objective measure and is the planning-level cost for the project, including technical services and contingency. "Advantageous" is indicated for the lowest cost alternative and any alternatives within 5% of the lowest cost. "Neutral" is indicated for other alternatives that are between 5% and 10% higher than the lowest cost alternative. "Disadvantageous" is indicated for alternatives that are 10% or more higher than the lowest cost alternative.
- Equivalent annual cost: This is an objective measure and is the planning-level equivalent annual cost for the project, including debt service on the capital cost and the annual O&M costs. "Advantageous" is indicated for the lowest cost alternative and any alternatives within 5% of the lowest cost. "Neutral" is indicated for other alternatives that are between 5% and10% higher than the lowest cost alternative. "Disadvantageous" is indicated for alternatives that are 10% or more higher than the lowest cost alternative.

- Technical viability: This is a subjective measure of viability. "Advantageous" is indicated for alternatives approved and in use in Massachusetts.
- Land area required: This is an objective/relative measure and represents total land area needed outside of the Cantonment for treatment and disposal.
- Availability of required land: This is a subjective measure and represents the ease with which land can be obtained. "Advantageous" is indicated for land within the Cantonment or the site currently "owned" by the 102nd ANG. "Neutral" is indicated for land in the Reserve/Northern Training Area. "Disadvantageous" is indicated for land owned by Federal agencies or the public.
- Permitting challenges: This is a subjective measure and represents the effort associated with obtaining the necessary regulatory permits. "Advantageous" is indicated for approaches currently approved in Massachusetts (RIBs and wicks). "Neutral" is indicated for approaches used elsewhere in Massachusetts but with significant technical hurdles at this location. "Disadvantageous" is indicated for approaches not currently approved in Massachusetts.
- Time required for implementation: This is a subjective measure and represents the time necessary to secure land and permits. This is a measure of availability of necessary land (ANL) and permitting challenges (PC). "Advantageous" is indicated only if ANL and PC are both advantageous. "Disadvantageous" is indicated if ANL and PC are both disadvantageous. "Neutral" is indicated for all others.
- Regulatory requirements/short-term: This is a subjective measure and represents the immediate/short-term regulatory framework. "Advantageous" is indicated for groundwater discharges outside of Zone II and with soil aquifer treatment in the unsaturated zone. "Neutral" is indicated for all others.
- Regulatory requirements/long-term: This is a subjective measure and represents the potential for additional effluent treatment parameters in the long-term. "Advantageous" is indicated for groundwater discharges outside of Zone II and with soil aquifer treatment in the unsaturated zone. "Neutral" is indicated for surface water discharges and discharges without soil aquifer treatment in the unsaturated zone.
- Operational flexibility: This is a subjective measure and represents the how much flexibility and redundancy is built into the treatment and disposal processes. All alternatives are intended to provide the same relative flexibility and redundancy.

- Operational complexity: This is an objective measure and represents the complexity of the overall treatment and disposal schematic. "Advantageous" is indicated for alternatives with no additional unit processes/disposal types. "Neutral" is indicated for alternatives with one or two additional unit processes/disposal types. "Disadvantageous" is indicated for alternatives with three or more additional unit processes/disposal types.
- Expandability: This is a subjective/relative measure and represents the ability of the alternative to be expanded in the future. "Disadvantageous" is indicated for RIBs because of the relatively large land footprint required for additional disposal capacity. "Neutral" is indicated for all other alternatives.
- Public perception: This is a subjective measure and represents the perception of the general public on the various alternatives. "Advantageous" is indicated for alternatives that would have no or very limited public profile. "Neutral" is indicated for alternatives that impact surface water. "Disadvantageous" is indicated for alternatives that impact drinking water.
- Non-Governmental Organization (NGO) perception: This is a subjective measure and represents the perception of non-governmental organizations on the various alternatives. "Advantageous" is indicated for no or very limited public profile. "Disadvantageous" is indicated for alternatives that impact surface water or drinking water.
- Sustainability/ groundwater supply: This is an objective measure and represents the whether the alternative recharges the drinking water supply. "Advantageous" is indicated for alternatives that do recharge the Zone II. "Disadvantageous" is indicated for alternatives that do not.
- Sustainability/ chemical use: This is an objective measure and represents whether chemical use will increase. "Advantageous" is indicated for alternatives that do not increase chemical use. "Neutral" is indicated for alternatives that add one chemical process. "Disadvantageous" is indicated for alternatives that add two or more chemical processes.
- Sustainability/ greenhouse gas emissions: This is a subjective/relative measure and represents the increase in energy use. "Advantageous" is indicated for alternatives that are substantially the same energy use. "Neutral" is indicated for alternatives that have a minor increase in energy use. "Disadvantageous" is indicated for alternatives that have a significant increase in energy use.

A summary of the evaluative criteria is presented in Table 2-6 and indicates the following:

- Option 1 – New WWTF with RIBs has the most Advantageous scores (10) and least Neutral scores (3).
- Option 2 – New WWTF with RIB/Wick has the most "Advantageous plus Neutral" scores (16) and the least Disadvantageous scores (1).
- Option 3 – New WWTF with RIB/DWI is tied for the most Disadvantageous scores (8).
- Option 4 – New WWTF with RIB/Outfall has the second highest "Advantageous plus Neutral" scores (14).
- Option 5 – New WWTF with DWI is tied for the most Disadvantageous scores (8).
- Option 6 – New WWTF with Outfall has the third highest "Advantageous plus Neutral" scores (13).

This matrix of alternatives identifies four options with essentially equivalent costs (with the RIB option being the lowest cost) and two options with higher costs (both options being DWI). All of these alternatives each have fairly challenging hurdles related to permitting, public perception, non-governmental organization perception, or all three.

[Remainder of this page is left intentionally blank]

TABLE 2-6: SUMMARY OF EVALUATIVE CRITERIA

Criteria A = Advantageous; N = Neutral; D = Disadvantageous	**1** **RIB**	**2** **RIB/Wick**	**3** **RIB/DWI**	**4** **RIB/Outfall**	**5** **DWI**	**6** **Outfall**
Capital Cost	A	A	D	A	D	A
Equivalent Annual Cost	A	A	D	A	D	A
Technical Viability	A	N	N	N	N	N
Land Area Required	D	A	A	N	A	N
Availability of Necessary Land	D	N	A	D	A	D
Permitting Challenges	N	N	D	N	D	N
Time Required for Implementation	N	N	N	N	N	N
Regulatory/ Short-Term	A	A	N	N	N	N
Regulatory/ Long-Term	A	A	N	N	N	N
Operational Flexibility	N	N	N	N	N	N
Operational Complexity	A	N	D	N	D	N
Expandability	D	N	N	A	N	A

Number of Disadvantageous Ratings	**4**	**1**	**8**	**3**	**8**	**4**
Number of Advantageous and Neutral Ratings	**13**	**16**	**9**	**14**	**9**	**13**

2.9.6 Cost Breakdown by Phase

The cost breakdown is based on Option 6 (Outfall) because it is the most conservative (i.e., most expensive) of the four composite alternatives that have relatively equivalent cost (i.e., Options 1, 2, 4 and 6). Costs for the phases break down as follows:

- Short-Term Costs – These costs consist of the items identified in Section 1.4 of this report as well as the conveyance costs for Bourne ISWM WWTF and Mashpee sewage.
- Mid-Term Costs – These costs consist of 65% of the ultimate treatment costs, 50% of the ultimate transport to disposal costs and 60% of the ultimate disposal costs as well as all of the conveyance costs for Bourne, Falmouth, Mashpee and Sandwich. These percentages were selected based on engineering judgment for the anticipated scope of work.
- Long-Term Costs – These costs consist of the remainder of the treatment, transport to disposal and disposal costs.

The cost breakdown by phase is presented in Table 2-7. Additional information is provided in Appendix A.

TABLE 2-7: CAPITAL COST BY PHASE (ENR CCI 10800)

	Short-Term	**Mid-Term**	**Long-Term**
Conveyance	$3.6M	$25.4M	$0M
Treatment	$1.9M	$25.6M	$13.8M
Transport	$0.3M	$11.8M	$11.8M
Disposal	$0.4M	$4.6M	$3.4M
Contingency, Technical, Legal, Admin., Finance	$2.7M	$29.1M	$12.5M
Total	$8.9M	$96.5M	$41.5M

2.9.7 Cost Allocation Among Participants

Costs for the various wastewater system components were allocated in the following ways:

- Conveyance – Costs were attributed to the individual towns, except where new or rehabilitated infrastructure is shared and except for baseline inflow removal at JBCC. When shared, the costs are split evenly among the affected individual towns. None of the conveyance costs were attributed to JBCC. Inflow removal costs associated with the existing system are the responsibility of JBCC. As noted earlier in this section, conveyance costs include the cost of the final lift station to convey flow to the JBCC system.
- Transport and Disposal – Costs were attributed to the individual towns and JBCC on a pro-rata flow basis, in accordance with the requested effluent disposal capacity indicated in Section 1.
- Contingency/Technical/Legal/Administration/Finance – Costs were attributed to the individual towns and JBCC pro-rata based on the subtotal of the planning-level construction costs.

The percentage of total effluent flow by phase is presented in Table 2-8. These percentages are used to allocate O&M costs. The basis for allocation of capital costs is presented in Table 2-9. This allocation was used for the mid-term and long-term conditions. The allocations of capital cost, annual O&M, and equivalent cost are presented in Table 2-10, Table 2-11 and Table 2-12, respectively. Additional information is presented in Appendix A.

TABLE 2-8: PERCENTAGE OF TOTAL EFFLUENT FLOW BY PHASE

	Short-Term	Mid-Term	Long-Term
JBCC	33%	9%	4%
Bourne	22%	42%	34%
Falmouth	0%	30%	45%
Mashpee	45%	12%	6%
Sandwich	0%	7%	11%
Total	100%	100%	100%

TABLE 2-9: BASIS FOR CAPITAL COST ALLOCATION (LONG-TERM FLOW)

	Annual Average Flow		% of Total	
	Treatment	Transport/ Disposal	Treatment	Transport/ Disposal
JBCC	147,000	147,000	13%	4%
Bourne	467,000	1,118,000	39%	34%
Falmouth	22,000	1,512,000	2%	45%
Mashpee	203,000	203,000	17%	6%
Sandwich	350,000	350,000	29%	11%
Total	1,189,000	3,330,000	100%	100%

TABLE 2-10: CAPITAL COST ALLOCATION (ENR CCI 10800)

	Short-Term	Mid-Term	Long-Term
JBCC	$1.5M	$5.6M	$3.5M
Bourne	$1.8M	$34.8M	$15.0M
Falmouth	$0M	$28.0M	$10.2M
Mashpee	$5.6M	$7.7M	$4.7M
Sandwich	$0M	$20.4M	$8.1M
Total	$8.9M	$96.5M	$41.5M

TABLE 2-11: ANNUAL O&M ALLOCATION (ENR CCI 10800)

	Short-Term	Mid-Term	Long-Term
JBCC	$0.23M	$0.13M	$0.10M
Bourne	$0.15M	$0.62M	$0.78M
Falmouth	$0M	$0.44M	$1.05M
Mashpee	$0.31M	$0.18M	$0.14M
Sandwich	$0M	$0.09M	$0.24M
Total	$0.69M	$1.46M	$2.31M

TABLE 2-12: EQUIVALENT ANNUAL COST ALLOCATION (ENR CCI 10800)

	Short-Term	Mid-Term	Long-Term
JBCC	$0.32M	$0.47M	$0.31M
Bourne	$0.26M	$2.74M	$1.70M
Falmouth	$0M	$2.16M	$1.67M
Mashpee	$0.65M	$0.65M	$0.43M
Sandwich	$0M	$1.34M	$0.74M
Total	$1.23M	$7.36M	$4.85M

Note:
1) Annual debt services on capital costs is calculated based on a CWSRF at 2% interest for 20 years (CRF 16.35).

It is important to note that cost allocations per entity will change if not all entities ultimately elect to participate or if entities elect to participate at higher or lower flow rates than indicated in Section 1 of this report. Cost allocations will also change if different allocation assumptions are utilized.

2.9.8 Comparison of Costs to Previous Town Planning Documents

This section of the report compares the capital cost allocation to cost estimates prepared as a part of previous planning documents prepared for each entity. This review is described below for each entity. The metric that will be used is "capital cost per thousand gallons of effluent in one year" (i.e., total costs divided by one year of effluent flow). For Alternative 6 (Outfall) in this report, the overall capital cost per thousand gallons of effluent per year is approximately $121 (JBCC SWMS). Additional supporting information is provided in Appendix A and Appendix C.

JBCC

Currently JBCC has a small customer base which results in relatively high unit costs for treatment and debt allocation. Bringing additional customers (i.e., other towns) will significantly reduce this cost burden in the short-term, mid-term and long-term. There is no sewer service expansion for JBCC, so there is no need to calculate or compare the cost metrics. The current operating budget for the JBCC facilities is approximately $0.5M per year, as compared to a project equivalent annual cost of $0.32M to $0.47M as shown on Table 2-12. Given that JBCC's existing operating budget

does not include any debt service (and the projected herein do include debt service), this shows a strong economy of scale for JBCC.

Bourne

Bourne completed wastewater planning for the portion of town north of the Cape Cod Canal in 2007 (as noted in Section 1), but has not completed wastewater planning for the portion of town south of the Cape Cod Canal. Using the Phase 1 wastewater flows and planning-level costs from the Bourne Wastewater Management Study (Tighe & Bond, 2007) and adjusting the costs to current dollars, the Bourne WMS indicates a capital cost per thousand gallons of effluent per year at approximately $162 in current dollars. This is 1.27 times than Bourne's share of the JBCC SWMS which is $127 in current dollars (see Appendix A). This shows a strong economy of scale for Bourne.

Falmouth

As a part of this project, Falmouth's wastewater planning consultant (GHD) was retained to develop a comparison of Falmouth costs under previous planning efforts to the Falmouth costs projected as a part of this evaluation. A technical memorandum from GHD is included in Appendix C. In short, the previous planning efforts indicate a capital cost per thousand gallons of effluent per year at approximately $107 to $170 in current dollars. As presented in Appendix C, Falmouth's projected share of the JBCC SWMS is $104 and $85 for mid-term and long-term, respectively. The JBCC SWMS is projected to cost Falmouth about the same in the mid-term as it planned in the DCWMP. The JBCC SWMS is projected to cost Falmouth less in the long-term than it planned in the DCWMP. Regionalization is expected to be a benefit to Falmouth.

Mashpee

As a part of this project, Mashpee's wastewater planning consultant (GHD) was retained to develop a comparison of Mashpee costs under previous planning efforts to the Mashpee costs projected as a part of this evaluation. A technical memorandum from GHD is included in Appendix C. In short, the previous planning efforts indicate a capital cost per thousand gallons of

effluent per year at approximately $78 for the recommended plan (i.e., connecting to JBCC with a smaller regional approach) and at approximately $207 for the backup plan (i.e., constructing a WWTF in Mashpee to treat and disposal of the same effluent volume), both in current dollars. As presented in Appendix C, Mashpee's projected share of the JBCC SWMS is $27, $130 and $193 for short-term, mid-term and long-term, respectively. These comparative numbers do not include the conveyance costs because they are equal between the WNMP and the JBCC SWMS approaches. The JBCC SWMS is projected to cost Mashpee substantially less in the short-term than was anticipated in the WNMP. The JBCC SWMS is projected to cost Mashpee more in the long-term than was anticipated in the WNMP; however, even at a higher cost, participating in a regional solution at JBCC is projected to cost less than Mashpee providing equivalent facilities on its own (i.e., working separately).

Sandwich

Sandwich completed town-wide wastewater planning in 2017. The Sandwich plan calls for two WWTFs, one near the Cape Cod Canal and one near the Sandwich Industrial Park. Using the wastewater flows and planning-level costs from the Sandwich draft Comprehensive Water Resources Management Plan (Wright-Pierce, 2017) and adjusting the costs to current dollars, the Sandwich CWRMP indicates a capital cost per thousand gallons of effluent per year at approximately $286 in current dollars. This is 1.28 times than Sandwich's share of the JBCC SWMS which is $223 in current dollars (see Appendix A). This shows a strong economy of scale for Sandwich.

Summary

As described on the previous pages, a regional approach appears to be generally favorable for the communities and JBCC and warrants continued consideration. A summary of the cost comparisons described on the previous pages is presented below in the units of "capital cost per thousand gallons of effluent capacity per year".

	JBCC Shared Wastewater Management Study	**Previous Planning Documents**
Bourne (sewage)	$127 (LT)	$162 (LT)
Bourne (leachate)	-	No information received
Falmouth	$85 (LT) to $104 (MT)	$107 to $170 (LT)
Mashpee	$27 (ST) to $193 (LT)	$78 (RP LT) to $207 (BP LT)
Sandwich	$223 (LT)	$286 (LT)

1. Refer to Appendix A for additional details regarding JBCC, Bourne and Sandwich.
2. Refer to Appendix C for additional details regarding Falmouth and Mashpee.
3. Cost metrics are based on October 2017 dollars (ENR CCI 10800). See Appendix A for more information.

It is important to note that these cost estimates are based on numerous key assumptions as described in this report, specifically including: the number of participants identified in Section 1.6; the capacity requests and timing of flows identified in Section 1.6; the phasing approach described in Section 2.8; and the loan financing terms identified in Section 2.9. Changes in these assumptions will result in adjustments to costs and cost allocations and may result in changes in cost comparisons. As more detailed cost information becomes available, these cost allocation comparisons should be refined.

SECTION 3

MANAGEMENT AND POLICY ISSUES

3.1 MANAGEMENT ENTITY

A publicly owned treatment works requires a management entity which must be able to fulfill the following common functions:

- **Planning.** Quantifying wastewater management needs; estimating wastewater flows; determining the necessary level of treatment; evaluating options for collection, treatment and disposal; identifying and evaluating sites; estimating project costs; and obtaining public input.
- **Land Acquisition.** Obtaining fee simple interest or easement rights for land for collection, treatment and disposal functions.
- **Permitting.** Obtaining all the permits and regulatory approvals to allow the proposed wastewater facilities to be built.
- **Design.** Selecting and contracting with design professionals to prepare plans and specifications for the facilities to be built.
- **Construction.** Bidding and issuing contracts for the construction of wastewater facilities, and overseeing the construction.
- **Operation.** Operating and maintaining the wastewater facilities including periodic replacement of failed equipment.
- **Monitoring.** Monitoring the performance of the wastewater facilities, reviewing the performance of the wastewater facilities against the permit requirements and conditions, and taking appropriate action in the event of noncompliance.
- **Funding.** Collecting and/or appropriating funds to pay the capital costs for wastewater facilities and the expenses for ongoing operation and maintenance.

In a successful program, all of the necessary functions will be accomplished without undue cost or complexity.

3.1.1 Initial Management Entity

MassDevelopment has been in discussions with the Air Force and the Air National Guard for several years regarding potentially acquiring ownership of the JBCC water and wastewater systems. MassDevelopment has successfully implemented a similar arrangement in Devens, Massachusetts (formerly Fort Devens). A final decision has not been made by MassDevelopment at the time of publication of this report. Other entities could serve as an initial (and successor) management entity; refer to Section 3.1.2 below.

3.1.2 Potential Successor Management Entities

The following potential successor management entities have been identified:

- **Host Town with Customer Agreements.** It is possible that ownership of the JBCC wastewater system could be transferred to one of the four towns, which in turn could enter into customer agreements with the other towns and the JBCC sewer users. This could make sense if one of the towns had the desire to undertake this significant responsibility. There may also be legal issues to address related to the fact that the WWTF is located in Sandwich and the effluent disposal system is located in Bourne.
- **Creation of a New Special Purpose District.** This approach would require an act of the Legislature to create a new special purpose district. This new district would presumably be established with a governing board representing each of the towns and JBCC. A new special purpose district seems to have significant merit because several towns may benefit from a regional facility, and the JBCC infrastructure is centrally located with respect to Bourne, Falmouth, Mashpee and Sandwich. A new special purpose district would require a number of implementation steps related to establishing a charter, hiring staff, securing office space, developing billing protocols, etc.
- **Modification of an Existing Special Purpose District.** This approach would modify the charter of an existing special purpose to undertake ownership responsibilities for the existing JBCC wastewater systems. A logical example of this approach is the Upper Cape Regional Water Supply Cooperative (UCRWSC) which was established by an act of the Massachusetts Legislature in 2000 and is governed by a Board of Managers with representatives from the

Bourne Water District, Town of Falmouth, Sandwich Water District and Mashpee Water District. This approach may be less logistically and administratively challenging than to create a new special purpose district.

3.1.3 Evaluative Criteria

Each of the management options described above has advantages and disadvantages which can be identified by considering the following evaluative criteria:

- **Ease in implementation**. If a new management structure is difficult to implement, there is less chance of success and higher cost to bring it to fruition.
- **Political acceptability.** The status quo would constitute an impediment to a new entity.
- **First costs to implement.** The ideal option would carry low costs for formation. It would also use existing public employees wherever possible.
- **Potential for long-term cost savings**. The more functions that can be handled regionally, the greater the potential for savings due to economies of scale.
- **Ability to raise money**. The principal means of financing wastewater projects has traditionally been through property taxation and betterment assessments. An effective entity should have access to funds through both means, and others if possible.
- **Loss of local control.** A regional entity will suffer from a real or perceived loss of local control. To the extent that decisions impacting cost, growth and environmental quality are made by someone other than the towns (and town meetings), there could be some opposition.
- **Ability to obtain grants and loans.** A regional entity would need to be carefully established such that the entity would be eligible for grants and loans for environmental infrastructure.

These criteria cover a broad range of issues. Individual towns or interest groups may have other criteria to add to this list, and may place differing emphasis on these criteria.

3.1.4 Summary of Management Entities

Given the options and evaluative criteria described above, a new or modified special purpose district would likely provide the most advantages to the customer communities and entities. The management entity could vary based on the individual wastewater system components. Suggested successor management entities organized by wastewater system component are summarized below. These elements are also schematically on Figure 2-5 by project phase (i.e., short-term, mid-term and long-term).

Wastewater System Component	**Suggested Successor Management Entity**
Collection	Individual towns
Conveyance	Special purpose district (or individual towns)
Treatment	Special purpose district
Transport to Disposal	Special purpose district
Disposal	Special purpose district

Ultimately, the selection of an approach will require input from staff, elected officials and legal counsel for each participating customer community as well as JBCC.

3.2 MULTIPLE PERMITTEES FOR EFFLUENT DISCHARGE PERMIT

This evaluation considers regional treatment at the existing or upgraded JBCC WWTF as well as shared disposal facilities for effluent treated at the JBCC WWTF, the Bourne ISWM WWTF and the Falmouth BSR WWTF. While the use of a single effluent disposal system for multiple WWTFs has been done before, it is far from common and requires that EPA and/or DEP consider the following important permitting factors:

- Sources of wastewater to the individual WWTFs (i.e., residential, commercial, industrial, septage, leachate);
- Treatment processes used at the individual WWTFs;
- Average and peak flow rates, jointly and severally;
- Effluent limits, monitoring requirements and monitoring locations for the individual WWTFs;

- Effluent limits, monitoring requirements and monitoring locations for the common disposal method;
- Legal and financial assurances for meeting effluent limits and groundwater quality standards; and
- Legal and financial assurance for asset management.

The management entity must have the ability to monitor effluent quality from the individual WWTFs and enforce effluent quality standards, or must have the other individual municipalities named as "co-permittees" on the permit. Discussions with DEP regarding the specifics of how the permit will be written should occur as soon as possible.

3.3 ALLOCATION OF AVAILABLE CAPACITY

In the long-term, each participating entity will secure the desired amount of capacity by committing an appropriate amount of the capital cost to the management entity. In the short-term, there is less capacity available than has been requested. It may be necessary to establish a method to allocate the available capacity until such time as the JBCC wastewater system is upgraded in the mid-term. There are numerous potential methods to allocate capacity. A listing of potential methods is provided below.

- Highest bidder
- Highest environmental benefit
- Quickest environmental benefit
- Highest economic benefit to communities
- Equalize economic benefit to communities
- First-come, first-served or "shovel-ready" projects

Each of these methods has some technical, political and financial trade-offs that should be discussed among the participants looking for short-term capacity.

3.4 INTER-MUNICIPAL/ INTER-GOVERNMENTAL AGREEMENTS

This project represents a potential regional approach to address wastewater management needs. It is expected that the remaining planning could take several years and may require one or more iterations to the cost model identified herein. It will be important that each participant clearly indicate its intentions to the other participants in order to converge on an acceptable solution. It is anticipated that one or more inter-municipal/inter-governmental agreements (IMA/IGA) may be necessary in order to implement the project.

- The initial IMA/IGA would commit the towns to collaboratively complete planning phase activities and to confirm conceptual capacity commitments and allocation of capacity in the short-term, mid-term and long-term. The initial IMA/IGA should include all potential participating entities.
- Subsequent IMA(s)/IGA(s) would be required to commit to flow neutral regulations, sewer use regulations, sewer user charges, and capital cost contributions in order to complete design, permitting and construction phase activities. It is envisioned that communities would enter into the subsequent IMAs/IGAs when they prepare to expend capital to connect to the wastewater system.

3.5 PRE-REQUISITES TO CAPITAL IMPROVEMENTS

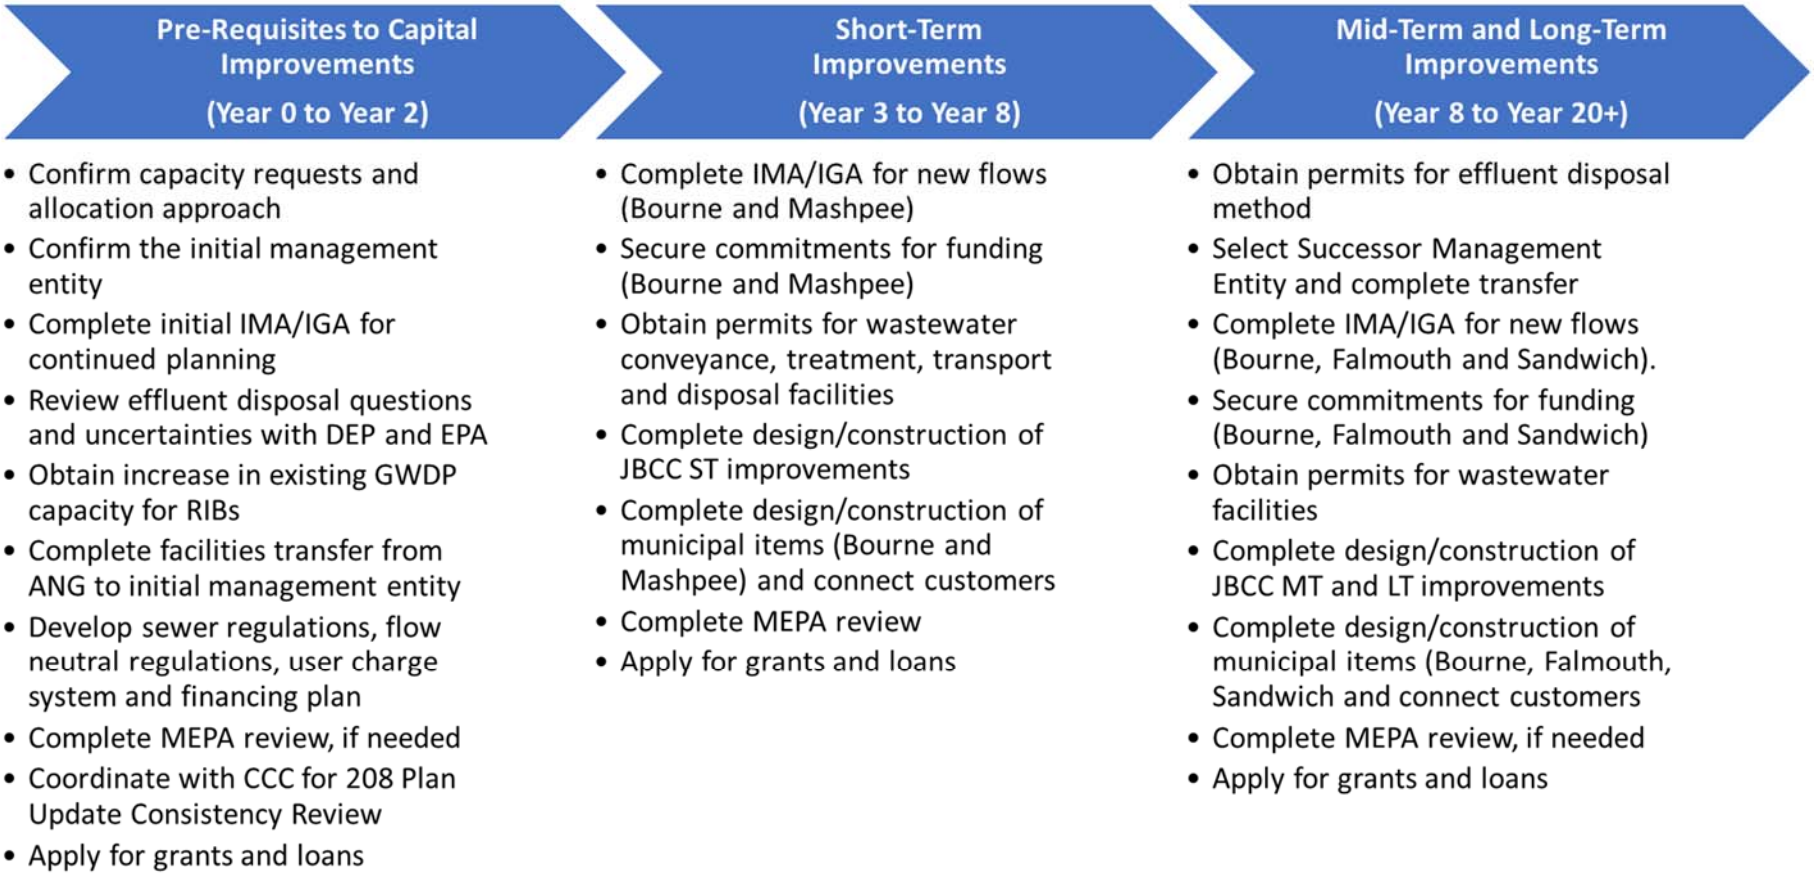
The following is a general list of pre-requisites to implementing any capital improvements related to providing capacity to regional participants beyond the existing system users.

- Complete planning, including confirming conceptual capacity commitments and developing consensus regarding allocation of capacity in the short-term.
- Confirm the initial management entity and complete the initial transfer of ownership
- Develop initial IMA/IGA
- Obtain increase in existing GWDP capacity (prior to short-term improvements)
- Obtain permit approvals from EPA and/or DEP for the selected disposal alternative (prior to mid-term improvements)

- Develop sewer regulations (all) and flow neutral regulations (towns), including coordination with local Boards of Health
- Develop sewer user charge system
- Develop a specific procurement and financing plan
- Secure commitments for the allocated capital costs, including design and permitting, via town meeting authorizations
- Secure commitments for the O&M rate structure
- Enact any special legislation necessary to implement the selected plan
- Acquire land and/or easements for conveyance, treatment, transport and disposal, as required
- Conduct Massachusetts Environmental Policy Act (MEPA) review
- Coordinate with Cape Cod Commission regarding the "208 Plan Update Consistency Review" [Note, the Commission has issued draft "Guidance on Section 208 Plan Update Consistency Review". The initial management entity would need to facilitate this review in coordination and collaboration with the four towns. The majority of the criteria for the consistency review are geared towards municipal planning by the designated Waste Treatment Management Agency (WMA). A proposed regional use of the JBCC wastewater system for the benefits of municipalities which are addressing water quality needs is consistent with the Commission's recommendations contained in Section 7 of the 208 Plan Update.]
- Complete design and obtain permitting for remainder of the project elements from EPA, DEP, local Town boards (Planning, Conservation, Historic District, etc.)
- Apply for grants and loans.

Figure 3-1 presents key pre-requisite activities by project phase.

FIGURE 3-1: DECISION FLOW CHART BY PROJECT PHASE



SECTION 4

CONCLUSIONS AND RECOMMENDATIONS

4.1 CONCLUSIONS

Based on our evaluations, we offer the following conclusions regarding the potential for expanding the JBCC wastewater system to serve as a regional facility:

- There is a regional need on the Upper Cape for facilities to provide wastewater treatment (short-term), septage treatment (mid-term) and effluent disposal (short-term, mid-term and long-term).
- Regionalizing the JBCC wastewater system provides economies of scale and provides apparent cost savings to the potential participating communities (based on capacity requests described herein).
- From a technical perspective, the advantages of regionalizing the JBCC wastewater system exceed the disadvantages. The municipalities will need to evaluate the advantages and disadvantages from political and policy perspectives.
- As described in Section 2, six composite alternatives were identified to provide regional facilities for wastewater treatment of the capacities requested by each municipality and JBCC. The composite alternatives are differentiated primarily by the effluent disposal method that is utilized.
  - Four of the six composite alternatives have essentially equal costs and collectively represent the lowest cost alternatives. These four composite alternatives are Rapid Infiltration Basins (Alternative 1), Rapid Infiltration Basins plus Wicks (Alternative 2), Rapid Infiltration Basins plus a Cape Cod Canal Outfall (Alternative 4) and a Cape Cod Canal Outfall (Alternative 6).
  - In the mid-term and long-term, Rapid Infiltration Basins and Wicks (Alternatives 1 and 2) will require some additional land near the existing disposal site and will require additional hydrogeologic study to obtain permit approvals. In the mid-term and long-term, a Cape Cod Canal Outfall (Alternatives 4 and 6) will require some additional land between the

existing disposal site and the Cape Cod Canal and will require additional study to address the requirements of the Massachusetts Ocean Sanctuaries Act (refer to Section 2.7.6).

- The use of Deep Well Injection in combination with Rapid Infiltration Basins (Alternative 3) has a substantially higher capital cost (1.12 times), annual O&M cost (2.48 times) and equivalent annual cost (1.39 times) than the lowest cost alternatives because Reverse Osmosis treatment processes are required at the WWTF. These differentials are related to the additional capital and operating costs associated with the reverse osmosis treatment process. Alternative 3 could be more cost competitive if there was additional flexibility allowed under Massachusetts regulations or if GAC treatment system could achieve similar requirements under the current regulations. Under either scenario, additional hydrogeologic study as well as pilot testing of Deep Well Injection and WWTF treatment processes would be required. The use of Deep Well Injection only (Alternative 5) should be ruled out at this time due to excessive costs; however, if the Cape Cod Canal were considered nitrogen-sensitive or the Sagamore Lens need additional recharge, then it may be appropriate to consider this alternative in the future.

- Each of the effluent disposal options described herein is allowed under Massachusetts law and regulation; however, each of the disposal options has site-specific challenges related securing permit approvals. These challenges are related to both technical factors and public perception. These challenges should be explored with DEP and EPA as a part of continued planning efforts.
- The cost allocation methodology presented herein is a flow-based allocation model. Other methods of cost allocation could be developed. If some communities choose not to participate, now or later, the capital costs and the cost allocation will change.
- A management entity for the regional facility must be established. Perhaps both as an interim management entity and as longer-term successor management entity. The long-term management entity is recommended to be a new or modified special purpose district.
- As more detailed cost information becomes available, these cost allocation comparisons should be updated and refined.

4.2 RECOMMENDATIONS AND IMPLEMENTATION STEPS

Based on our evaluations, there are sufficient advantages to the participating municipalities and JBCC to warrant continued planning efforts. The following continued planning activities should be a high priority in order to advance this effort:

Activities	**Responsible Party**
Prepare initial letters of support from each participating community.	Towns, JBCC
Secure additional grant funds or local funds from each participating community to continue planning activities identified in Figure 3-1.	Falmouth (as fiscal agent)
Prepare and execute the initial IMA/IGA as described in Section 3.4.	Towns, JBCC
Complete tasks needed to facilitate acceptance of Bourne landfill leachate effluent from the ISWM WWTF.	Bourne
Complete tasks needed to facilitate acceptance of Mashpee sewage.	Mashpee
Coordinate with DEP and EPA regarding DWI, Canal outfall, wicks and RIB permitting issues and uncertainties.	All
Initiate tasks to increase the capacity of the existing RIBs.	All

MEMORANDUM

TO:	File	**DATE:**	8/23/2017, rev 11/27/2017
FROM:	Ed Leonard	**PROJECT NO.:**	13839A
SUBJECT:	JBCC Shared Wastewater Management Study Flow Estimate Backup Materials		

Attached are the following cost estimate backup materials:

1. Basis for Bourne Flows to JBCC Wastewater Facilities
2. Bourne Wastewater Management Study, Figure 2-5
3. Supporting Information for Table 1-8
4. TR-16 Flow Peaking Factor Chart
5. Supporting Information for Table 2-2

Basis for Bourne Flows

The Bourne Wastewater Management Study (Tighe & Bond, 2007) included estimates of existing and future wastewater flow town-wide, as summarized in Table 3-4 of the Bourne WMS, and an assessment of "priority", as shown on Figure 2-5 (attached). The prioritization approach is presented in Section 2.5 of the Bourne WMS and includes consideration of: performance of existing on-site wastewater systems; location relative to 100-year flood plain; location relative to low permeability soils; and location relative to estuaries and coastal embayments.

The Bourne WMS did not assess or estimate off-site wastewater management needs; accordingly, a cursory assessment was conducted in order to support the JBCC SWMS effort. The wastewater flows are summarized on the attached table entitled "Basis for Bourne Flows to JBCC Wastewater Facilities" dated 22 Aug 2017. The following assumptions were utilized in preparing these estimates:

- Wastewater flow identified for off-site treatment and disposal was estimated by the following percentages using the information presented on Bourne WMS Figure 2-5: 25% for low priority (blue, green); 50% for medium priority (yellow, orange); and 75% for high priority (red).

- Wastewater flow does not cross the Cape Cod Canal.
- Wastewater flow from Areas 8 through 14 (except Area 11) goes to the ISWM WWTF location and is connected to the effluent forcemain along with the leachate flow. Area 11 (MacArthur Boulevard/Route 28) is split equally between the ISWM and JBCC WWTFs.
- Wastewater flow from Areas 15 to 20 goes to the JBCC WWTF location and is treated as sewage.
- Septage goes to the JBCC WWTF.

Bourne confirmed via email on 8/15/2017 and 8/23/2017 that the attached flow estimates were suitable for use in this planning effort. Bourne will need to develop a more detailed assessment of off-site wastewater management needs as a part of a town-wide or targeted watershed management planning effort.

Total - Septage Capacity				0	11,000	11,000
Total - Effluent Disposal Only				100,000	444,000	651,000
Total - Effluent Disposal				100,000	714,000	1,118,000

NOTES:
1) Estimated flows based on Tighe & Bond Table 3-4 and 3-9. All flows presented as annual average flows.
2) Estimated flows based on Tighe & Bond Figure 2-5 using the following: blue and green = 25%, yellow and orange = 50%, red = 75%.
3) Estimated flows to ISWM WWTF will be for effluent disposal capacity and estimated flow to JBCC WWTF will be for sewage capacity.

MEMORANDUM

TO:	File	**DATE:**	10/26/2017
FROM:	E. Whatley, J. Ducharme	**PROJECT NO.:**	13839A
SUBJECT:	JBCC Shared Wastewater Management Study Evaluation of Conveyance Options		

This memorandum identifies the options for wastewater conveyance systems required to support shared wastewater management opportunities for the towns of Bourne, Falmouth, Mashpee, Sandwich and Joint Base Cape Cod (JBCC). Supplemental information is included in the following attachments:

- Conveyance Option Worksheet with plan and profile figures
- Conveyance Options Costs
- JBCC Conveyance Improvement Worksheet

1.1 OBJECTIVES

The objectives of the conveyance study include the following:

- Identify alignments for conveyance of sewage from Bourne's southern section, Mashpee and Sandwich to JBCC WWTF for treatment and disposal;
- Identify alignments for conveyance of treated wastewater ("effluent") from the JBCC WWTF, the Bourne ISWM WWTF and the Falmouth BSR WWTF to the JBCC treated effluent conveyance system and disposal areas;
- Identify rehabilitation of sections of the JBCC gravity sewer system where shorter alignments and capital cost savings are available;
- Review conceptual profiles of each forcemain alignment to evaluate conceptual static and dynamic head on the pumping system;
- Develop preliminary hydraulic calculations to determine conceptual forcemain sizes; and
- Determine conceptual number and size of required lift stations.

1.1.1 Concept Design Criteria

The following key assumptions are used in this analysis:

- Elevation data was obtained from topographic information within Google Earth.
- Conceptual forcemain piping and wastewater lift station sizing are based on the conveyance flows in Tables 1 and 2.

TABLE 1 RAW WASTEWATER CONVEYANCE FLOWS

(Raw Wastewater Lift Station Peaking Factor: 4)

Flow Source	Existing Flows		Short-Term Flows		Mid-Term Flows		Long-Term Flows

Sandwich	-	-	-	-	110,000	95	350,000	304
Total Effluent Disposal	140,000	122	452,000	392	1,691,000	1,468	3,335,000	2,895

- Raw wastewater concept design criteria:
    - Peaking factor used for lift station flow: 4.0
    - Minimum forcemain velocity: 3 fps
    - Maximum forcemain design pressure: 275 ft (120 psi)
- Effluent concept design criteria:
    - Peaking factor used for lift station flow: 1.25
    - Minimum forcemain velocity: none
    - Maximum forcemain design pressure: 275 ft (120 psi)
- Forcemain materials:
    - Existing effluent forcemain: ductile iron
    - Proposed forcemains: C900/C905 DR 18 PVC (235 psi) or HDPE (200 to 255 psi)
- Pump calculations:
    - Method: Hazen-Williams with friction value of 130
    - Pump Horsepower approximation per Hydraulic Institute method
- Medium-sized wastewater and effluent lift stations:
    - Flow: up to 1200 gpm
    - Pumps: submersible, up to 75 hp
    - Wetwell and valve vault
    - Generator and control panel in pump house
    - Conceptual construction cost: $1M each
- Large-sized wastewater and effluent lift stations:
    - Flow: 1200 gpm or more
    - Pumps: drypit installation, greater than 75 hp
    - Generator and control panel in pump building over wetpit/drypit installation
    - Conceptual construction cost: $2.5M each

- Conveyance routes utilizing existing JBCC gravity conveyance systems assume the rehabilitation of those sections through trenchless methods. Rehabilitation costs are assumed to be $150 per foot.
- Forcemain costs vary depending on the conditions of the route and are shown below in Table 3. A route within a public way with heavy traffic volumes or dense development has a higher cost than a route along routes with little traffic or adjacent development.

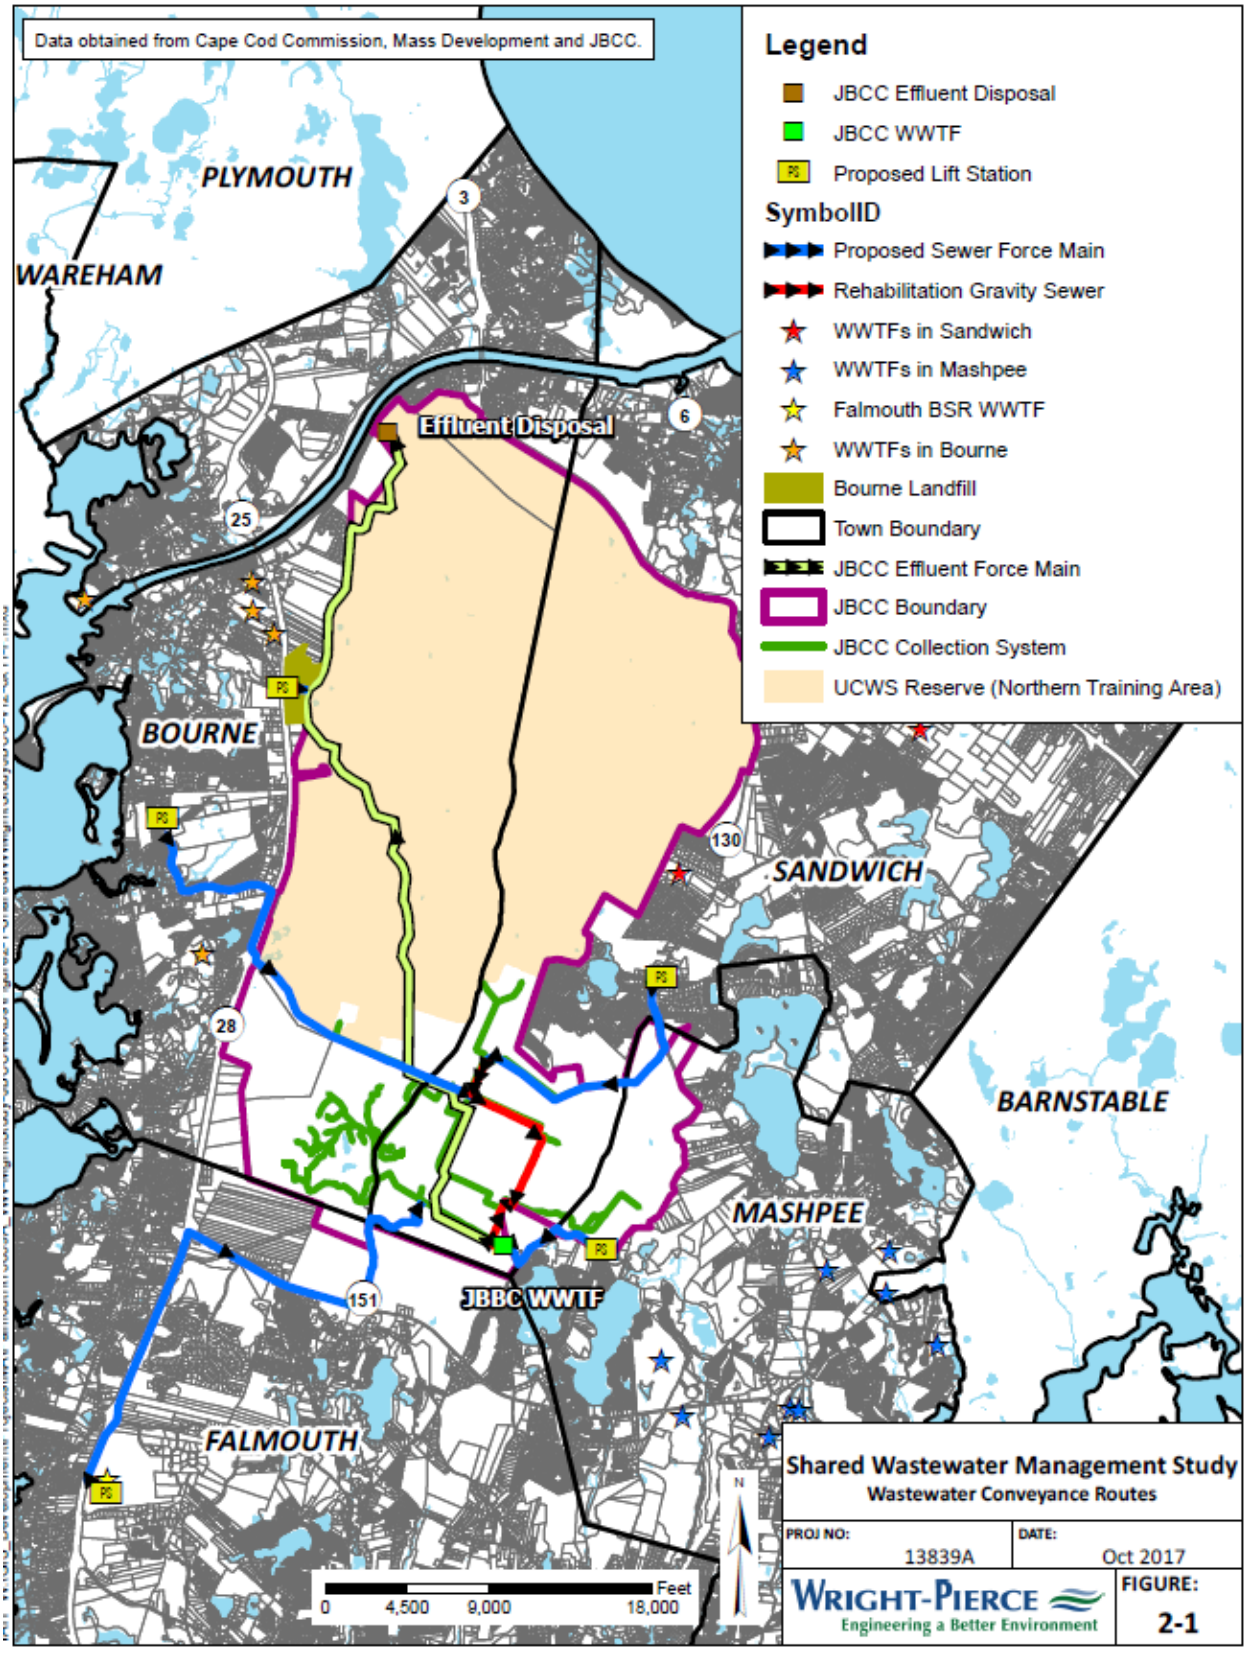
TABLE 3: FORCEMAIN UNIT COSTS

Forcemain Diameter	Route Characteristics		
	Public Way/Dense (Cost/ft)	Off Public Way or Less Dense (cost/ft)	Railroad Right of Way (cost/ft)
8-inch	$200	$120	$300
10-inch	$220	$140	$320
12-inch	$240	$160	$340
14-inch	$260	$180	$360
18-inch	$280	$200	$380

1.2 SUMMARY OF PREFERRED CONVEYANCE OPTIONS

Current preferred conveyance routes are shown on **Figure 2-1** and identified as follows:

- Bourne North (effluent) – Proposed lift station at ISWM WWTF connected to existing JBCC effluent forcemain, via a new 8" Bourne forcemain.
- Bourne South – Proposed lift station at the intersection of Valley Bars and County Roads to JBCC WWTF via a new 12" Bourne forcemain and rehabilitated gravity sewer (shared with Sandwich).
- Falmouth (effluent) – Proposed lift station at BSR WWTF connected to the JBCC effluent forcemain(s) via a new 18" Falmouth forcemain in Routes 28 and 151.
- Mashpee – Proposed lift station on Back Road Site 1 (Town lot) to JBCC WWTF via new 8" Mashpee forcemain.
- Sandwich – Proposed lift station on portion of Lot-06-236 at 40 Route 130 to JBCC WWTF via 12" Sandwich forcemain, and rehabilitated gravity sewers (shared with Bourne).



Data obtained from Cape Cod Commission, Mass Development and JBCC.

1.3 CONVEYANCE ALIGNMENTS EVALUATED

1.3.1 Bourne Alignments

The following alignments were investigated for Bourne sewage flow from the southern sections of town. This piping is required in the mid-term.

- Option 1. Shortest route through the JBCC base, utilizing existing JBCC gravity sewer
    - 1 large lift station, 1250 gpm, 235 ft TDH, 150 hp
    - 12" forcemain, velocity 3.6 fps, 5.1 miles
    - JBCC rehabilitated gravity sewer, 2.3 miles
    - Total route length: 7.4 miles
    - Advantages
        - Least expensive - by $4.1M
        - Shortest route by 2.1 miles
        - Shortest length within public way / dense route
    - Disadvantages
        - Uncertainty of obtaining construction easements within federal lands for forcemains
        - Uncertainty of the level of rehabilitation required for JBCC gravity sewers
- Option 2A. Route utilizing the Shining Sea bike corridor, 1 lift station
    - 1 large lift station, 1400 gpm, 250 ft TDH, 175 hp
    - 14" forcemain, velocity 3.0 fps, 9.5 miles
    - Total route length, 9.5 miles
- Option 2B. Route utilizing the Shining Sea bike corridor, 2 lift stations
    - 2 large lift stations, 1250 gpm, 175 ft TDH, 100 hp
    - 12" forcemain, velocity 3.6 fps, 9.5 miles
    - Total route length, 9.5 miles
- Option 3A. Route primarily in public way
    - 1 large lift station, 1400 gpm, 250ft TDH, 175 hp

  - 14" forcemain, velocity 3.0 fps, 9.9 miles
  - Total route length, 9.9 miles

- Option 3B. Route primary in public way
  - 2 large lift stations, 1250 gpm, 175 ft TDH, 120 hp
  - 12" forcemain, velocity 3.6 fps, 9.9 miles
  - Total route length, 9.9 miles

Bourne Option 2A, 2B, 3A and 3B appear to be less favorable option based on the following:

- Advantage
  - Avoids having to obtain extensive construction easements within federal lands for forcemains
  - Avoids concern over the level of rehabilitation required for JBCC gravity sewers
- Disadvantage
  - High costs

One alignment was investigated for Bourne effluent flow from the ISWM WWTF to the JBCC effluent forcemain. We assumed the construction of a medium sized lift station to accommodate long-term conditions.

  - 1 medium lift stations, 570 gpm, 180 ft TDH, 50 hp, Velocity 1.7 fps
  - Existing 8" Forcemain, 100 feet

A summary of the Bourne-South Options is shown below.

TABLE 4: BOURNE CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2A	Option 2B	Option 3A	Option 3B
Cost	$M	9.9	14.0	15.5	16.0	17.5
Rehabilitated JBCC sewer (50% Share)	1000 ft	12.3	0.0	0.0	0.0	0.0
Medium PS (Bourne – North)	Each	1	1	1	1	1
Large PS	Each	1	1	2	1	2
Forcemain in public way/dense	1000 ft	12.7	38.5	38.5	17.8	17.8
Forcemain off public way/less dense	1000 ft	14.5	13.5	13.5	32.2	32.2

1.3.2 Falmouth Alignments

The following alignments were investigated for Falmouth effluent flow from the BSR WWTF to the JBCC WWTF effluent forcemain. This piping is required in the mid-term.

- Option 1. Route in public way
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 6.7 miles
    - Total route length, 6.7 miles
    - Advantages
        - Least expensive by $100,000
        - Eliminates potentially expensive railroad coordination costs in Option 3
    - Disadvantage
        - Lengthy section of the route is in right of way
- Option 2. Route in public way, with semi-utilization of the Shining Sea bike corridor
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 8.1 miles
    - Total route length. 8.1 miles
    - Advantages
        - Shorter section of the route is in right of way
        - Eliminates potentially expensive railroad coordination costs in Option 3
    - Disadvantage
        - More expensive than Option 1 by $1M
- Option 3. Route in public way and rail right of way
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 5.3 miles
    - Total route length, 5.3 miles
    - Advantages
        - Shortest route
        - Potential to be less expensive with favorable railroad coordination costs

- Disadvantages
  - Costs associated with railroad safety and flagmen expenses during construction and regular operation
  - Efficient access to the rail corridor during and after construction
  - Potential damage from vibration caused by rail traffic

A summary of the Falmouth Conveyance Options is shown below.

TABLE 5: FALMOUTH CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2	Option 3
Cost	$M	11.7	12.7	11.8
Large PS	Each	1	1	1
Forcemain in public way/dense	1000 ft	25.9	20.1	13.8
Forcemain in railroad right of way	1000 ft	0.0	0.0	14.2
Forcemain off public way/less dense	1000 ft	9.5	22.6	0.0

1.3.3 Mashpee Alignments

The following alignments were investigated for Mashpee sewage flow to the JBCC WWTF. This piping is required in the short-term.

- Option 1. Mashpee forcemain to connect directly to JBCC WWTF
  - Medium lift station, 560 gpm, 75 ft TDH, 20 hp
  - 8” Dedicated Mashpee forcemain, velocity 3.5 fps, 1.4 miles
  - Total route length: 1.4 miles
  - Advantages
    - Least expensive by $1.7M
    - Shortest forcemain route by 3.4 miles
    - Reduced lift station size
    - Smaller diameter force main
  - Disadvantages
    - None

- Option 2. Mashpee forcemain to shared rehabilitated gravity main with Sandwich and Bourne
    - Medium lift station, 1040 gpm, 140 ft TDH, 70 hp
    - 12" Dedicated Mashpee forcemain, velocity 3.0 fps, 4.2 miles
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 4.8 miles
    - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be cost advantages for Mashpee.
    - Advantages
        - Forcemain would be dedicated to Mashpee and maintaining correct operating conditions would be easier for Mashpee.
        - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be cost advantages for Mashpee.
    - Disadvantages
        - More expensive than Option 1 by $2.4M. (Note: Mashpee Option 3 requires Sandwich to choose Option 2 which is $0.8M more expensive for Sandwich).
- Option 3. Mashpee forcemain to forcemain shared with Sandwich and rehabilitated gravity main shared with Sandwich and Bourne
    - Medium lift station, 1040 gpm, 140 ft TDH, 70 hp
    - 12" Dedicated Mashpee forcemain, velocity 3.0 fps, 2.4 miles
    - 12" S Outer Road forcemain, 0.7 miles, shared with Sandwich
    - 12" Reilly Rd/Grandville Ave forcemain, 1.1 miles, shared with Sandwich
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 4.8 miles
    - Advantages

        - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be additional cost advantages.
    - Disadvantages
        - More expensive than Option 1 by $1.7M.

A summary of the Mashpee options is shown below.

TABLE 6: MASHPEE CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2	Option 3
Cost	$M	2.5	4.9	4.2
Rehabilitated JBCC sewer (33% Share)	1000 ft	0	3.4	3.4
Medium PS	Each	1	1	1
Forcemain in public way/dense	1000 ft	7.5	3.0	3.0
Forcemain off public way/less dense	1000 ft	0	18.9	9.7
Forcemain off public way/less dense - 50% share with Sandwich	1000 ft	0	0.0	9.3

1.3.4 Sandwich Alignments

The following alignments were investigated for Sandwich sewage flow to the JBCC WWTF. The conveyance system is required in the mid-term.

- Option 1. Sandwich forcemain to connect to shared rehabilitated gravity main with Bourne
    - Medium lift station, 1050 gpm, 75 ft TDH, 40 hp
    - 12” Dedicated Sandwich forcemain, velocity 3.0 fps, 2.9 miles
    - JBCC rehabilitated gravity sewer, 0.4 miles
    - JBCC rehabilitated gravity sewer, 1.7 miles, shared with Bourne
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne
    - Total route length: 5.7 miles
    - Advantages
        - Least expensive by $0.8M
        - Shortest forcemain route by 0.9 miles
    - Disadvantages

        - Uncertainty of obtaining construction easements within federal lands for forcemains
        - Uncertainty of the level of rehabilitation required for JBCC gravity sewer mains.

- Option 2. Sandwich forcemain to connect shared forcemain with Mashpee (Mashpee Option 2) and shared rehabilitated gravity main with Bourne and Mashpee
    - Medium lift station, 1050 gpm, 140 ft TDH, 60 hp
    - 12" Dedicated Sandwich forcemain, velocity 3.0 fps, 4.2 miles
    - 12" S Outer Road forcemain, 0.7 miles, shared with Mashpee
    - 12" Reilly Rd/Grandville Ave forcemain, 1.1 miles, shared with Mashpee
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 6.6 miles
    - Advantages
        - If Mashpee implements Option 2, there would be cost savings with implementation of Sandwich Option 2.
    - Disadvantages
        - More expensive by $0.8M

TABLE 7: SANDWICH CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2
Cost	$M	5.0	5.8
Rehabilitated JBCC sewer (100% Share)	1000 ft	2.2	0.0
Rehabilitated JBCC sewer (50% Share)	1000 ft	12.3	3.4
Medium PS	Each	1	1
Forcemain in public way/dense	1000 ft	3.5	3.5
Forcemain off public way/less dense	1000 ft	11.9	18.3
Forcemain off public way/less dense – share with Mashpee	1000 ft	0.0	9.3

1.3.5 Effluent Conveyance Systems

The effluent conveyance system will require improvements to accommodate anticipated flow increases in each phase.

- Existing Conveyance System Data
    - Existing forcemain
        - 12-inch diameter
        - 10.8 miles
        - Ductile iron
        - Design friction factor, C, 130
        - Distance to high point, 5.8 miles (30,600 feet)
        - Static head: 210 feet
    - Existing system design assumptions
        - Conveyance main operates as a forcemain to the high point and forcemain friction calculations are based on 5.8 miles.
        - From the high point, around 150 feet of head is available to drive flow to the RIB's. A flow of about 1500 gpm uses up the available head.
        - With one pump running at the JBCC WWTF, there is available capacity in the short term for Bourne to discharge treated effluent into the JBCC forcemain at the ISWM.

1.4 SCHEDULE OF IMPROVEMENTS

1.4.1 Short-term improvements:

- JBCC / All Participants
    - Maintain operation of existing lift station and forcemain
    - Accommodate flows from JBCC and Mashpee arriving at the effluent lift station (252,000 gpd / peaked pump flow of 320 gpm)

- Bourne
  - At the ISWM, install a lift station designed to accommodate mid-term and long-term flows
  - Make connection to existing JBCC forcemain
  - Install additional valves and stubs to make a future connection to new effluent forcemains without disrupting service.
- Falmouth – no changes
- Mashpee
  - Construct Mashpee lift station and forcemain conveying flow to the WWTF.
- Sandwich – no changes

1.4.2 Mid-term improvements:

- JBCC / All Participants
  - Maintain operation of existing lift station and forcemain
  - Accommodate effluent from JBCC, Bourne-South, Mashpee and Sandwich in the existing effluent forcemain (peaked pump flow of 640 gpm)
  - Construct new parallel forcemain from Falmouth connection to the RIB's with interconnection valving with existing 12-inch forcemain
- Bourne
  - Connect ISWM forcemain into new 18-inch forcemain (peaked flows increase from 87 to 385 gpm)
  - Construct Bourne Option 1 including lift station, forcemain and JBCC gravity sewer rehabilitation
- Falmouth
  - Construct Falmouth 18-inch forcemain to valving interconnection with existing 12-inch forcemain and new 18-inch forcemain
  - Direct Falmouth flow to new 18-inch forcemain (peaked pump flow of 444 gpm)
- Mashpee – no changes
- Sandwich

- Construct Sandwich lift station, forcemain and JBCC gravity sewer rehabilitation

1.4.3 Long-term improvements

- JBCC / All Participants
  - Construct second 18-inch effluent forcemain and interconnections
- Bourne
  - Connect discharge from ISWM WWTF to second JBCC 18-inch forcemain

MEMORANDUM

TO:	File	**DATE:**	11/27/2017
FROM:	Ed Leonard	**PROJECT NO.:**	13839A
SUBJECT:	JBCC Shared Wastewater Management Study Cost Estimate Backup Materials		

Attached are the following cost estimate backup materials:

1. Costs for Conveyance Alternatives (Existing/ Short-Term/ Mid-Term/ Long-Term)
2. Costs for Treatment, Transport-to-Disposal and Disposal Alternatives (Long-Term)
3. Costs for Composite Wastewater Management Alternatives (Long-Term)
4. Cost Allocation for Composite Wastewater Alternative, Option 6 (All Phases)
5. Cost Comparison for Bourne and Sandwich

re: JBCC
Shared Wastewater Management Study
Hydrogeologic Considerations
GHC #17017

Dear Mr. Leonard:

At Wright-Pierce's request, GeoHydroCycle, Inc. (GHC) looked into the geohydrologic considerations related to Rapid Infiltration Basins, Wicks, and Deep Injection Wells at Joint Base Cape Cod (JBCC).

Rapid Infiltration Basins

GeoHydroCycle, Inc. (GHC) conducted groundwater mounding for the existing 4 Rapid Infiltration Beds (RIBs) located in the northern portion of JBCC near the Cape Cod Canal. The goal of this work has been to estimate the effects of groundwater mounding under wastewater loading conditions greater than the permitted rate. Groundwater mounding was accomplished with the finite difference model MODFLOW following MassDEP guidelines[1]. Input data for the model came from available data and information at JBCC and other available online sources.

Based on the modeling results, the assessment showed that the existing RIBs have the capacity to receive treated wastewater at 1.55 million gallons per day without causing: 1) mounding that would exceed MassDEP design requirements; or 2) breakout along the land surface in the down gradient direction toward the Cape Cod Canal.

Figure 1 shows a cross-section through the JBCC RIB area starting at the Cape Cod Canal and extending approximately one mile south away from the Canal. As the figure shows, natural groundwater flows toward the Cape Cod Canal, and beneath the RIB area there is at least 70 feet separation between groundwater and the land surface. Even as groundwater approaches the Canal, the vertical separation remains between 5 and 10 feet below ground surface.

(617) 527-8668 (f)

[1] Massachusetts DEP. November 2014. *Guidelines for the Design, Construction, Operation, and Maintenance of Small Wastewater Treatment Facilities with Land Disposal.*

GeoHydroCycle, Inc.

Figure 2 shows the results of a groundwater mounding simulation where wastewater was discharged into the 4 RIBs at a rate of 1.295 mgd, or 5 gpd/sf into all 4 beds. Because MassDEP allows the use of 80% of the daily maximum wastewater discharge in groundwater mounding models, the actual discharge would be 1.619 mgd, which is more than double the 0.800 mgd permitted for the RIBs. Figure 2 demonstrates that the discharge would only cause a 12 foot increase in groundwater levels beneath the 4 RIBs.

Figure 3 shows groundwater elevation contours that would result from adding the groundwater mound heights onto local groundwater. As Figure 3 shows, although the mounded groundwater is at elevation 30, it is still 60 feet below the land surface at the JBCC RIBs, and down gradient of the RIBs the mounded groundwater remains well below the land surface.

Existing information indicates that the hydrogeologic conditions beneath the adjacent property to the west is very similar to what exists beneath the JBCC RIBs. Based on this information, GHC would expect that additional sets of RIBs located on available property to the west of the existing RIBs would exhibit similar mound heights when the new RIBs are all loaded at 5.0 gpd/sf.

Wicks

Wicks, a relatively new technology in Massachusetts, provide a useful and cost effective disposal option. The significant depth to water table and glacial outwash soils at JBCC provide the conditions were wicks can be successful. Wicks can be thought of as large diameter wells that provide a vertical conduit transmitting wastewater down to the water table. For a given discharge, Wicks use less land area than conventional disposal technologies and can be used to transmit effluent vertically through tight soils to more conductive hydrogeologic formations.

Deep Well Discharge

GeoHydroCycle, Inc. compiled hydrogeologic information relative to three possible deep discharge well sites within the JBCC Cantonment Area. The goal of this work was to look at different types of hydrogeologic conditions that would either positively or negatively affect the placement of a deep well to discharge treated wastewater at a particular site. GHC downloaded and reviewed online USGS data to accomplish this goal.

Figure 4 shows JBCC in the western portion of Cape Cod and the five towns (Falmouth, Bourne, Sandwich, Barnstable and Mashpee) around the base. The Cantonment Area is located in the southern portion of JBCC, and Figure 4 shows the possible locations of three deep wells, DW-1, DW-2 and DW-3. Figures 5, 6 and 7 show the geologic makeup of the soils at the three deep well locations. Those figures also show the types of soil around the well, the hydraulic properties of the soils, and the depth range of the screened entrance for municipal wells in the vicinity of the deep well.

(617) 527-8668 (f)

GeoHydroCycle, Inc.

Soil types can be used to infer the general ability of the well to discharge water to groundwater. Typically, sands and gravels provide a much better media for discharge wells than do silts or clays. Soil hydraulic conductivity is also a good indicator of a well's ability to act as a discharge well. The greater the hydraulic conductivity, the greater the well's ability to discharge to groundwater. A municipal well's screen is where water is drawn into the well, and the greater the separation depth between the deep well's screen and the municipal well's screen, the less likely it is for the municipal well to draw in deep well wastewater.

The placement of the deep wells took into consideration the location of municipal well Zone IIs or wellhead protection areas. Wells DW-1 and DW-2 were located outside Zone IIs and well DW-3 was located within a Zone II. A Zone II is defined by state regulations as that land area that provides water to a municipal well under drought conditions, and the location of a deep well discharging treated wastewater in a Zone II would be considered negatively under current regulations even with a large vertical separation. On a technical basis there should be a large enough vertical separation to allow deep well injection without impacting municipal wells.

Figure 8 presents possible groundwater pathways from each deep well to the ocean. This figure is based on general groundwater contours published by the Cape Cod Commission. As Figure 8 shows groundwater in the area of deep well DW-2 flows to the west toward Buzzards Bay, and could be expected to travel 15,000 feet in groundwater before reaching the Bay. Deep wells DW-1 and DW-3 travel with groundwater to the south toward Vineyard Sound, but the travel path for both wells is much longer, 7.4 and 8.4 miles respectively. The further travel distances, and times, provide more opportunity for the wastewater to be drawn upward and end up discharging to one of the many ponds or estuaries instead of the ocean. The longer flow paths also adversely change the natural groundwater quality of a much larger volume of groundwater than do shorter pathways.

Injection wells are a new technology for Cape Cod and the location, design and capacity of the wells would be determined only through large-scale testing. The ability to bypass coastal embayments would need to be further demonstrated through detailed groundwater modeling.

If you have any questions, please feel free to call me.

Sincerely,
GeoHydroCycle, Inc.

Stephen W. Smith, P.E., P.HGW.

Memorandum

November 28, 2017

To:	Ed Leonard – Wright Pierce	Ref. No.:	11151818
From:	J. Jefferson Gregg, P.E., BCEE	Tel:	774-470-1640
CC:	Rodney Collins – Town of Mashpee, MA Amy Lowell – Town of Falmouth, MA		
Subject:	**Cost Review – JBCC Shared Wastewater Management Study** **Towns of Falmouth, MA and Mashpee, MA**		

1. Introduction

GHD Inc. was contracted by Wright Pierce for consulting services as part of their Joint Base Cape Cod (JBCC) Shared Wastewater Management Study through a grant received by the Town of Falmouth, MA. The data in this memorandum is provided subject to the limitations in Section 6.0.

GHD's tasks included review of draft documents provided by Wright Pierce related to their efforts on the project, attendance at a workshop held at the Mashpee Town Hall on October 18, 2017 with the other project participants, and then provide general comments on the draft documents and the costs presented. The general review of preliminary costs was done on behalf of the communities of Falmouth, MA and Mashpee, MA and would be based on existing planning documents developed by GHD for those two communities. No new costs were to be developed as part of this evaluation. Comparison was made following the Wright Pierce phasing framework of Short Term (2017 to 2020), Mid Term (2020 to 2040) and Long Term (2040+).

The existing planning documents referenced for comparison are as follows:

- "Shared Watershed Management Study: Towns of Bourne, Falmouth, Mashpee, Sandwich and Joint Base Cape Cod – Preliminary Strategy and Engineering Assessment Report – DRAFT", Town of Falmouth, Ma, October 2017, Wright Pierce. (JBCC Report)
- "Final Recommended Plan/ Final Environmental Impact Report", Town of Mashpee Sewer Commission, May 2015, GHD Inc. (WNMP)
- "Draft Comprehensive Wastewater Management Plan and Draft Environmental Impact Report, and Notice of Project Change – Little Pond, Great Pond, Green Pond, Bournes Pond, Eel Pond, and Waquoit Bay Watersheds and Recommendations for West Falmouth Harbor Watershed – Volume 1 and 2", Town of Falmouth, MA, July 2012, GHD Inc. (DCWMP/DEIR)

Supplemental information was also consulted as it related to the previous GHD planning efforts and past cost development for both Falmouth, MA and Mashpee, MA.

2. Task 3 General JBCC Report Review

On October 16, 2017, GHD was provided with the JBCC DRAFT Report for review and comment prior to the October 18, 2017 workshop. GHD identified the following comments summarized as follows: (Wright Pierce general responses are summarized in *italics*)

1. Section 1.3.3 "Mashpee" – GHD requested that reference to the July 31, 2015 Certificate of the Secretary of Energy and Environmental Affairs on the Final Environmental Impact Report be included in this section. *Reference will be included in final document.*
2. Section 1.4.8, last bullet – GHD suggested clarification be provided on where the 8-inch FM section is, as all other references to the effluent FMs at JBCC are of 12-inch pipe. *Clarification will be provided in final document.*
3. Section 1.6.3, first paragraph, 3rd sentence. Should read "advantageous", not "advantages". *Correction made in final document.*
4. Table 1-7 Requested Capacity By Wastewater Type, following discussions with the Town of Mashpee. Please revise two rows:
    a. Mid Term – High End (gpd) change from 200,000 gpd to 370,000 gpd
    b. Long Term – High End (gpd) change from 200,000 gpd to 850,000 gpd

    It is our understanding that these changes in values do not impact the Study Basis or Cost Estimations. *Table 1-7 will be modified per the request, and values do not impact Study Basis.*
5. Section 2.4.2, fourth bullet "Mashpee (sewage)"; Mashpee requested that the location of the lift station be made consistent with the approved WNMP. There is no lift station proposed at the Mashpee Rotary to convey wastewater to JBCC. GHD provided additional information during discussions with Wright Pierce regarding the location of the pumping station to JBCC. During that discussion, GHD suggested two potential options:. either at the "Back Road Site 1" location as shown on Figure 6-4, or at the proposed lift station location proposed for Subarea "L" off of Hooppole Road. *WP will show pumping station at Back Road Site 1.*
6. Section 2.4.2.3 – Preferred Mashpee Alignment Details. See Comment #5.
7. Table 2-4 Unit Processes – suggested that Deep Well Injection and Outfall would be the same for "Conventional Nitrogen" either both "yes" or both "no". *Correction made in final document.*
8. Sections 2.8.2, 2.84 and 2.8.6 – suggested that Mid-Term first bullet be clarified. Is the assumption that they currently meet these requirements, or that they will by the time of Mid-Term implementation. *Additional clarification will be provided in final document.*
9. GHD asked if there would be a table presenting the "Short-Term" breakdown. GHD suggested that a simple table of % contribution by each town under the Short-, Mid-, and Long-Term options be presented. *Updates provided by WP.*

10. Section 2.9.4 –"Conveyance", GHD asked if cost splitting by flow contribution was considered for shared infrastructure? *It was clarified that other methods were not considered for this report, but it is acknowledged that other methods could be used.*

11. Section 2.9.6 – Evaluation Criteria.

    a. Public perception – GHD asked why impact to surface water was considered "neutral", isn't there concern over ocean outfalls and the public perception – wouldn't this be the same as the "NGO" perception? *It was clarified that public perception was considered different than NGO perception on this topic, but that this is a subjective criteria.*

    b. Groundwater Protection – GHD suggested modifying this title or breaking into two categories, as it could be interpreted that "protection" and "sustainability" might be different relative to Zone IIs. *It was clarified that this would be changed to "Sustainability/Groundwater supply". Groundwater protection is covered by permitting.*

    c. Sustainability/chemical use – GHD asked if there was consideration of decrease in chemical use as the advantage. *It was clarified that chemical use was related to the number of processes, not chemical quantities*.

12. Appendix A – Evaluation Conveyance Options memo should be updated – see Comment #5. *Correction will be made in final document.*

3. Task 4 Mashpee Review

The following tables summarize the analysis used to look at capital costs for various options.

GHD has elected to evaluate the wastewater treatment and recharge option components at JBCC, and compare then to similar options identified as part of the Mashpee WNMP. As part of the Mashpee WNMP, JBCC was considered for treatment and recharge. In order to compare to the JBCC Report, the following considerations were made:

1. The WNMP considered treatment at JBCC using their existing facilities and presumed that only improvements to the existing WWTF would be necessary. Conveyance costs were included in their overall collection system costs and were not broken out separately. In addition, it was assumed for the JBCC option that the existing rapid infiltration basins (RIBs)/open sand beds would be sufficient to handle the flows recommended.

2. An alternative to the WNMP sending flow to JBCC was to construct new facilities at the "Back Road Site 1". This evaluation considers an MBR for treatment and recharge at open sand beds.

3. These WNMP options were then compared to the JBCC-Option 1 which included SBRs and RIBs.

4. Conveyance costs were not considered since they are considered each town's responsibility, thus these costs were not broken out in the WNMP..

5. Costs were then calculated on a dollars per thousand gallon treated ($/Kgal) per Wright-Pierce's request. Each component was calculated individually and then added up to consider those conditions where flow may change between what is being treated and what is being recharged.

Table 3.1 presents the summary of the Short-Term costs prepared by Wright-Pierce for the Treatment and Disposal options.

Table 3.2 presents the summary of the Mid-Term costs prepared by Wright-Pierce for the Treatment and Disposal options.

Table 3.3 presents the summary of the Long-Term costs prepared by Wright-Pierce for the Treatment and Disposal options.

Table 3.4 presents a summary of the WNMP costs prepared for the following three options:

1. Phase 2 (JBCC Option) – this option is the recommended plan, where 200,000 gpd would be sent to JBCC and treated using the existing facilities (expanded with a parallel oxidation ditch added), and recharged using the existing RIBs.
2. Phase 2 (Back Roads Site - MBR) – This option represents the "fall back" option presented in the Recommended Plan if the JBCC facility was not available to Mashpee. This would include a new WWTF and RIBs.

Table 3.5 presents the comparison between each option and identifies each option by high, medium, and lowest capital cost on a $/Kgal basis.

Table 3.1 Short-Term - Mashpee

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Baseline Treatment Only					
WP-Option 6	200,000	$1,090,000	$468,700	$1,558,700	$21
Supplemental Treatment Only					
WP-Option 6	200,000	$-	$-	$-	$-
Disposal (with Transport) Only					
WP-Option 6	200,000	$309,734	$133,186	$442,920	$6
Total					
WP-Option 6 - WWTF and Recharge (RIB)					$27

Notes:
1. Costs are based on values prepared by Wright-Pierce in their Draft October 2017 report and appendices.
2. Conveyance Costs Not included, because locations could vary when compared to each alternative (including CWMPs) and all Costs by Town only.
3. Contingency column represents "Contingencies/Fiscal, Legal, Engineering" (43%) differ from those for the WNMP (40% assumed in WNMP).

Table 3.2 Mid-Term - Mashpee

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Baseline Treatment Only					
WP-Option 6	203,000	$5,443,338	$2,340,635	$7,783,973	$105
Supplemental Treatment Only					
WP-Option 6	203,000	$-	$-	$-	$-
Disposal (w/ Transport) Only					
WP-Option 6	203,000	$1,310,126	$563,354	$1,873,480	$25
Total					
WP-Option 6 - WWTF and Recharge (RIB)					$130

Notes:
1. Costs are based on values prepared by Wright-Pierce in their Draft October 2017 report and appendices.
2. Conveyance Costs Not included, because locations could vary when compared to each alternative (including CWMPs) and all Costs by Town only.
3. Contingency column represents “Contingencies/Fiscal, Legal, Engineering” (43%) differ from those for the WNMP (40% assumed in WNMP).

Table 3.2 Long-Term - Mashpee

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Baseline Treatment Only					
WP-Option 6	203,000	$7,786,169	$3,348,053	$11,134,222	$150
Supplemental Treatment Only					
WP-Option 6	203,000	$-	$-	$-	$-
Disposal (w/ Transport) Only					
WP-Option 6	203,000	$2,236,257	$961,591	$3,197,848	$43
Total					
WP-Option 6 - WWTF and Recharge (RIB)					$193

Notes:
1. Costs are based on values prepared by Wright-Pierce in their Draft October 2017 report and appendices.
2. Conveyance Costs Not included, because locations could vary when compared to each alternative (including CWMPs) and all Costs by Town only.
3. Contingency column represents “Contingencies/Fiscal, Legal, Engineering” (43%) differ from those for the WNMP (40% assumed in WNMP).

Table 3.3 Mashpee WNMP (2015)

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Treatment Only					
Phase 2 JBCC Option	200,000	$4,000,000	$1,720,000	$5,720,000	$78
Phase 2 Back Roads Site	200,000	$9,860,000	$4,240,000	$14,100,000	$193
Disposal (w/ Transport) Only					
Phase 2 JBCC Option	200,000	$-	$-	$-	$-
Phase 2 Back Roads Site	200,000	$720,000	$310,000	$1,030,000	$14
Total					
Phase 2 (JBCC Option)					$78
Phase 2 (Back Roads Site - MBR)					$207

Notes:
1. Contingency column represents “Contingency/Fiscal, Legal, Engineering” changed to 43% to match JBCC evaluation (40% assumed in WNMP).
2. Base line cost adjusted from 2015 values (ENR 9922) to 2017 Costs per JBCC ENR (10800).
3. Mashpee Alternative assumed no improvements needed to effluent recharge facilities at JBCC.
4. Mashpee Alternative assumed existing JBCC WWTF could be used and expanded vs. construction of a new WWTF.

Table 3.4 Mashpee Summary ($/Kgal)

Option	Mashpee WNMP (JBCC)	Mashpee WNMP (Back Roads - MBR)	JBCC Short-Term	JBCC Mid-Term	JBCC Long-Term
WW Treatment and Recharge (RIB)	$78	$207	$27	$130	$193

Notes:
1. RIB = Rapid Infiltration Basin/Open Sand Bed
2. Green = Lowest Cost
3. Orange = Mid Cost
4. Red = High Cost

As can be seen in Table 3.4, the Mashpee WNMP recommended plan presents the lowest capital cost option. This is primarily because it does not call for an entirely new WWTF and does not require construction of new

RIBs. O&M costs were not compared directly as there was no breakout by “process”, “town”, and “option” provided for the JBCC report.

4. Task 5 – Falmouth Review

The following tables summarize the analysis used to look at capital costs for various options. Comparisons are strictly made in an effort to compare cost development for this JBCC Report relative to previous planning efforts in Falmouth, MA and are not intended to represent any recommended plan for Falmouth, MA as they are currently still in the midst of Comprehensive Planning.

GHD has elected to evaluate the wastewater treatment and recharge option components at JBCC and compare then to similar options identified as part of the evaluations performed in developing the Falmouth Draft CWMP/DEIR. As part of the Falmouth Draft CWMP planning efforts, several alternatives for JBCC were considered for treatment and recharge. The Town of Falmouth is still in planning, has been working on addressing their TMDLs through multiple approaches, and has not finalized any recommendation regarding the use of JBCC; therefore comparisons are made based on evaluations performed as part of the Draft CWMP development back in 2009 and 2012. In order to compare to the JBCC Report, the following considerations were made:

1. Conveyance costs were included in their overall collection system costs and were not broken out separately.
2. Costs for Falmouth were based on those developed as part of the DCWMP/DEIR. It should be noted that these were not the final recommendations of the Town; however they were used as they provided a group of comparable scenarios.
3. Costs were then calculated on a dollars per thousand gallon treated ($/Kgal) per Wright-Pierce request. Each component was calculated individually and then added up to consider those conditions where flow may change between what is being treated and what is being recharged.
4. Option 6 (as outlined in Section 2 of the JBCC Report was used as the evaluation point) – New WWTF at JBCC and ocean outfall (OO) (Falmouth continues treatment at the existing BSR WWTF)
5. O&M costs were not compared directly as there was no breakout by “process”, “town”, and “option” provided for the JBCC report.

Table 4.1 presents the summary of the Mid-Term costs prepared by Wright-Pierce for the Treatment and Disposal options, plus upgrade costs for the BSR WWTF to continue treatment in the long-term. Upgrade costs represent the portion of the costs that would be sent to JBCC for effluent disposal (i.e., Falmouth would have additional upgrade costs for the effluent flow that would stay in Falmouth).

Table 4.2 presents the summary of the Long-Term costs prepared by Wright-Pierce for the Treatment and Disposal options, plus upgrade costs for the BSR WWTF to continue treatment in the long-term. Upgrade costs represent the portion of the costs that would be sent to JBCC for effluent disposal (i.e., Falmouth would have additional upgrade costs for the effluent flow that would stay in Falmouth).

Table 4.3 presents a summary of the DCWMP/DEIR costs prepared for the following three options:

1. 3A - JBCC WWTF with Recharge at the Falmouth County Club (FCC).
2. 3C - JBCC WWTF with RO and Well Injection.
3. 1D – Blacksmith Shop Road (BSR) WWTF with Ocean Outfall.

These options were considered the most comparable to the JBCC Report options, based on their treatment and discharge technologies.

Table 4.4 presents the comparison between each option and identifies each option by high, medium, and lowest capital cost on a $/Kgal basis.

Table 4.1 Mid Term – Falmouth

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Baseline Treatment Only					
WP-Option 6	512,000	$6,297,248	$2,707,816	$9,005,064	$48
Supplemental Treatment Only					
WP-Option 6	512,000	$-	$-	$-	$-
Disposal (w/ Transport) Only					
WP-Option 6	512,000	$7,451,190	$3,204,012	$10,655,202	$56
Total					
WP - Option 6 - WWTF and Recharge (OO)					$104

Notes:
1. Costs are based on values prepared by Wright Pierce in their Draft October 2017 report and appendices.
2. Conveyance Costs Not included, because locations could vary when compared to each alternative (including CWMPs) and all Costs by Town only.
3. Contingency column represents “Contingencies/Fiscal, Legal, Engineering” (43%) differ from those for the CWMP (50% assumed in DCWMP/DEIR).
4. Treatment flows and costs adjusted to account for off-site (not at JBCC) wastewater treatment. Estimated $/Kgal used based on Option 1D of the DCWMP/DEIR for 490,000 gpd balance.

Table 4.2 Long Term - Falmouth

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Baseline Treatment Only					
WP-Option 6	1,512,000	$18,440,041	$7,929,218	$26,369,259	$48
Supplemental Treatment Only					
WP-Option 6	1,512,000	$-	$-	$-	$-
Disposal (w/ Transport) Only					
WP-Option 6	1,512,000	$14,349,266	$6,170,184	$20,519,450	$37
Total					
WP - Option 6 - WWTF and Recharge (OO)					$85

Notes:

1. Costs are based on values prepared by Wright Pierce in their Draft October 2017 report and appendices.
2. Conveyance Costs Not included, because locations could vary when compared to each alternative (including CWMPs) and all Costs by Town only.
3. Contingency column represents “Contingencies/Fiscal, Legal, Engineering” (43%) differ from those for the CWMP (50% assumed in DCWMP/DEIR).
4. Treatment flows and costs adjusted to account for off-site (not at JBCC) wastewater treatment. Estimated $/Kgal used based on Option 1D of the DCWMP/DEIR for 1,490,000 gpd balance.

Table 4.3 Falmouth DCWMP/DEIR (2009/2012)

Scenario	Flow (gpd)	Baseline Cost ($)	Contingency (43%)	Subtotal ($)	$/Kgal
Treatment Only					
3A (Phase 1 and 2) Table 5-1	1,800,000	$32,700,000	$14,100,000	$46,800,000	$71
3C (Phase 1 and 2) Table 5-4	1,800,000	$68,000,000	$29,200,000	$97,200,000	$148
1D (Phase 1 and 2) - Table 5-5	1,800,000	$21,400,000	$9,200,000	$30,600,000	$47
Disposal (w/Transport) Only					
3A (Phase 1 and 2) Table 5-1	1,800,000	$16,400,000	$7,100,000	$23,500,000	$36
3C (Phase 1 and 2) Table 5-4	1,800,000	$10,100,000	$4,300,000	$14,400,000	$22
1D (Phase 1 and 2) - Table 5-5	1,800,000	$47,900,000	$20,600,000	$68,500,000	$104
Total					
3A (Phase 1 and 2) Table 5-1					$107
3C (Phase 1 and 2) Table 5-4					$170
1D (Phase 1 and 2) - Table 5-5					$151

Notes:

1. 3A - JBCC WWTF with Recharge at FCC
2. 3C - JBCC WWTF with RO and Well Injection
3. 1D - BSR WWTF with Ocean Outfall
4. Conveyance cost based on Major PS and FM cost row from spreadsheets
5. Contingency column represents “Contingency/Fiscal, Legal, Engineering” changed to 43% to match JBCC evaluation
6. Base line cost adjusted from July 2009 values (ENR 8570) to 2017 Costs per JBCC ENR (10800)

Scenario Flow (gpd)	Estimated $/Kgal
DCWMP WW Treatment and Recharge (RIB)	$107
DCWMP WW Treatment and Recharge (DWI)	$170
DCWMP WW Treatment and Recharge (OO)	$151
Option 6 – Mid-Term (JBCC Report)	$104
Option 6 – Long-Term (JBCC Report)	$85

Notes:

1. RIB = Rapid Infiltration Basin/Open Sand Bed
2. DWI = Deep Well Injection
3. OO = Ocean Outfall
4. Green = Lowest Cost
5. Orange = Mid Costs
6. Red = High Costs

5. Summary

Based on this initial review of the documents and costs:

- The Mashpee WNMP recommendations (i.e., to send 200,000 gpd of sewage to JBCC upgaded for a smaller scale regional use) still appear to be the most cost effective for that community, however, the Mashpee WNMP was not intended to consider a larger scale regional use of the JBCC facility. If all of the communities were in agreement and a larger effluent discharge option were presented, the Town of Mashpee may consider requesting additional sewage treatment capacity in order to alleviate stress on its existing embayments. At this time the short-term goals of Mashpee appear consistent with the short-term goals presented in the JBCC report.
- The Falmouth DCWMP/DEIR costs indicate that it is slightly less cost effective for Falmouth to work independently in the long term and essentially the same under mid-term conditions. Irrespective of the term, the Town is in the middle of its planning efforts and changes and alternatives identified during that process may show the JBCC alternatives more cost effective. The alternatives for Falmouth were much closer in cost than those presented for Mashpee.
- There are still a significant number of unknowns regarding the use of JBCC which would influence each of these communities and their future decision making process; however, the planning-level cost estimates are indicative of potential cost savings in the long-term due to regionalization. Mashpee and Falmouth should continue to stay engaged on the potential regional use of the JBCC wastewater facilities.

6. Limitations

GHD has not been involved in the direct preparation of the JBCC Report and makes no statement in the JBCC Report other than the contents of this memorandum.

The Cost Estimates are a preliminary estimate only. Actual prices, costs, and other variables may be different to those used to prepare the Cost Estimate and may change. No detailed quotation has been obtained for actions identified herein. GHD does not represent, warrant or guarantee that the works/project can or will be undertaken at a cost which is the same or less than the Cost Estimates presented.

No information provided as part of this memorandum shall be used for design or construction.

MEMORANDUM

TO:	File	**DATE:**	5/13/2019
FROM:	E. Whatley, J. Ducharme, J. Srey	**PROJECT NO.:**	13839/20008A
SUBJECT:	JBCC Shared Wastewater Management Study Evaluation of Conveyance Options		

This memorandum identifies the options for wastewater conveyance systems required to support shared wastewater management opportunities for the towns of Bourne, Falmouth, Mashpee, Sandwich, Joint Base Cape Cod (JBCC), and Barnstable. Supplemental information is included in the following attachments:

- Conveyance Option Worksheet with plan and profile figures
- Conveyance Options Costs
- JBCC Conveyance Improvement Worksheet

1.1 OBJECTIVES

The objectives of the conveyance study include the following:

- Identify alignments for conveyance of sewage from Barnstable, Bourne's southern section, Mashpee and Sandwich to JBCC WWTF for treatment and disposal;
- Identify alignments for conveyance of treated wastewater ("effluent") from the JBCC WWTF, the Bourne ISWM WWTF and the Falmouth BSR WWTF to the JBCC treated effluent conveyance system and disposal areas;
- Identify rehabilitation of sections of the JBCC gravity sewer system where shorter alignments and capital cost savings are available;
- Review conceptual profiles of each forcemain alignment to evaluate conceptual static and dynamic head on the pumping system;
- Develop preliminary hydraulic calculations to determine conceptual forcemain sizes; and
- Determine conceptual number and size of required lift stations.

1.1.1 Concept Design Criteria

The following key assumptions are used in this analysis:

- Elevation data was obtained from topographic information within Google Earth.
- Conceptual forcemain piping and wastewater lift station sizing are based on the conveyance flows in Tables 1 and 2.

TABLE 1: RAW WASTEWATER CONVEYANCE FLOWS

(Raw Wastewater Lift Station Peaking Factor: 4)

Total Effluent Disposal	**140,000**	**122**	**452 ,000**	**392**	**2,191,000**	**1,902**	**4,535,000**	**3,937**

- Raw wastewater concept design criteria:
    - Peaking factor used for lift station flow: 4.0
    - Peaking factor used for Barnstable lift station flow: 3.6
    - Minimum forcemain velocity: 3 fps
    - Maximum forcemain design pressure: 275 ft (120 psi)
- Effluent concept design criteria:
    - Peaking factor used for lift station flow: 1.25
    - Minimum forcemain velocity: none
    - Maximum forcemain design pressure: 275 ft (120 psi)
- Forcemain materials:
    - Existing effluent forcemain: ductile iron
    - Proposed forcemains: C900/C905 DR 18 PVC (235 psi) or HDPE (200 to 255 psi)
- Pump calculations:
    - Method: Hazen-Williams with friction value of 130
    - Pump Horsepower approximation per Hydraulic Institute method
    - Assumed pump efficiency for sewage: 50%
    - Assumed pump efficiency for effluent: 65%
- Medium-sized wastewater and effluent lift stations:
    - Flow: up to 1200 gpm
    - Pumps: submersible, up to 75 hp
    - Wetwell and valve vault
    - Generator and control panel in pump house
    - Conceptual construction cost: $1M each

- Large-sized wastewater and effluent lift stations:
    - Flow: 1200 gpm to 2000 gpm
    - Pumps: drypit installation, greater than 75 hp
    - Generator and control panel in pump building over wetpit/drypit installation
    - Conceptual construction cost: $2.5M each
- Very large-sized wastewater and effluent lift stations:
    - Flow: 2000 gpm or more
    - Pumps: drypit installation
    - Horsepower: up to 200 hp
    - Generator and control panel in pump building over wetpit/drypit installation
    - Conceptual construction cost: $5M each
    - For pumps requiring 300 hp, add an additional $1M.
- Air release structures
    - Located at high points
    - Conceptual construction costs: $25,000 each
- Conveyance routes utilizing existing JBCC gravity conveyance systems assume the rehabilitation of those sections through trenchless methods for options that do not include Barnstable. Rehabilitation costs are assumed to be $150 per foot. For options that include Barnstable, new gravity sewers required accommodate large flows are assumed to be $300 per foot.
- Forcemain costs vary depending on the conditions of the route and are shown below in Table 3. “Public Way/Dense” refers to a route within a public way with heavy traffic volumes or dense development and has a higher cost than a route referred to as “Public Way/Less Dense” which includes routes within a public way with little traffic. Force main costs assume full-depth trench paving and full-width mill and overlay.
- For the large-diameter effluent force main routes through JBCC, the costs for 18-inch and 20-inch force mains are approximates $200 /LF and $210 / LF, respectively.

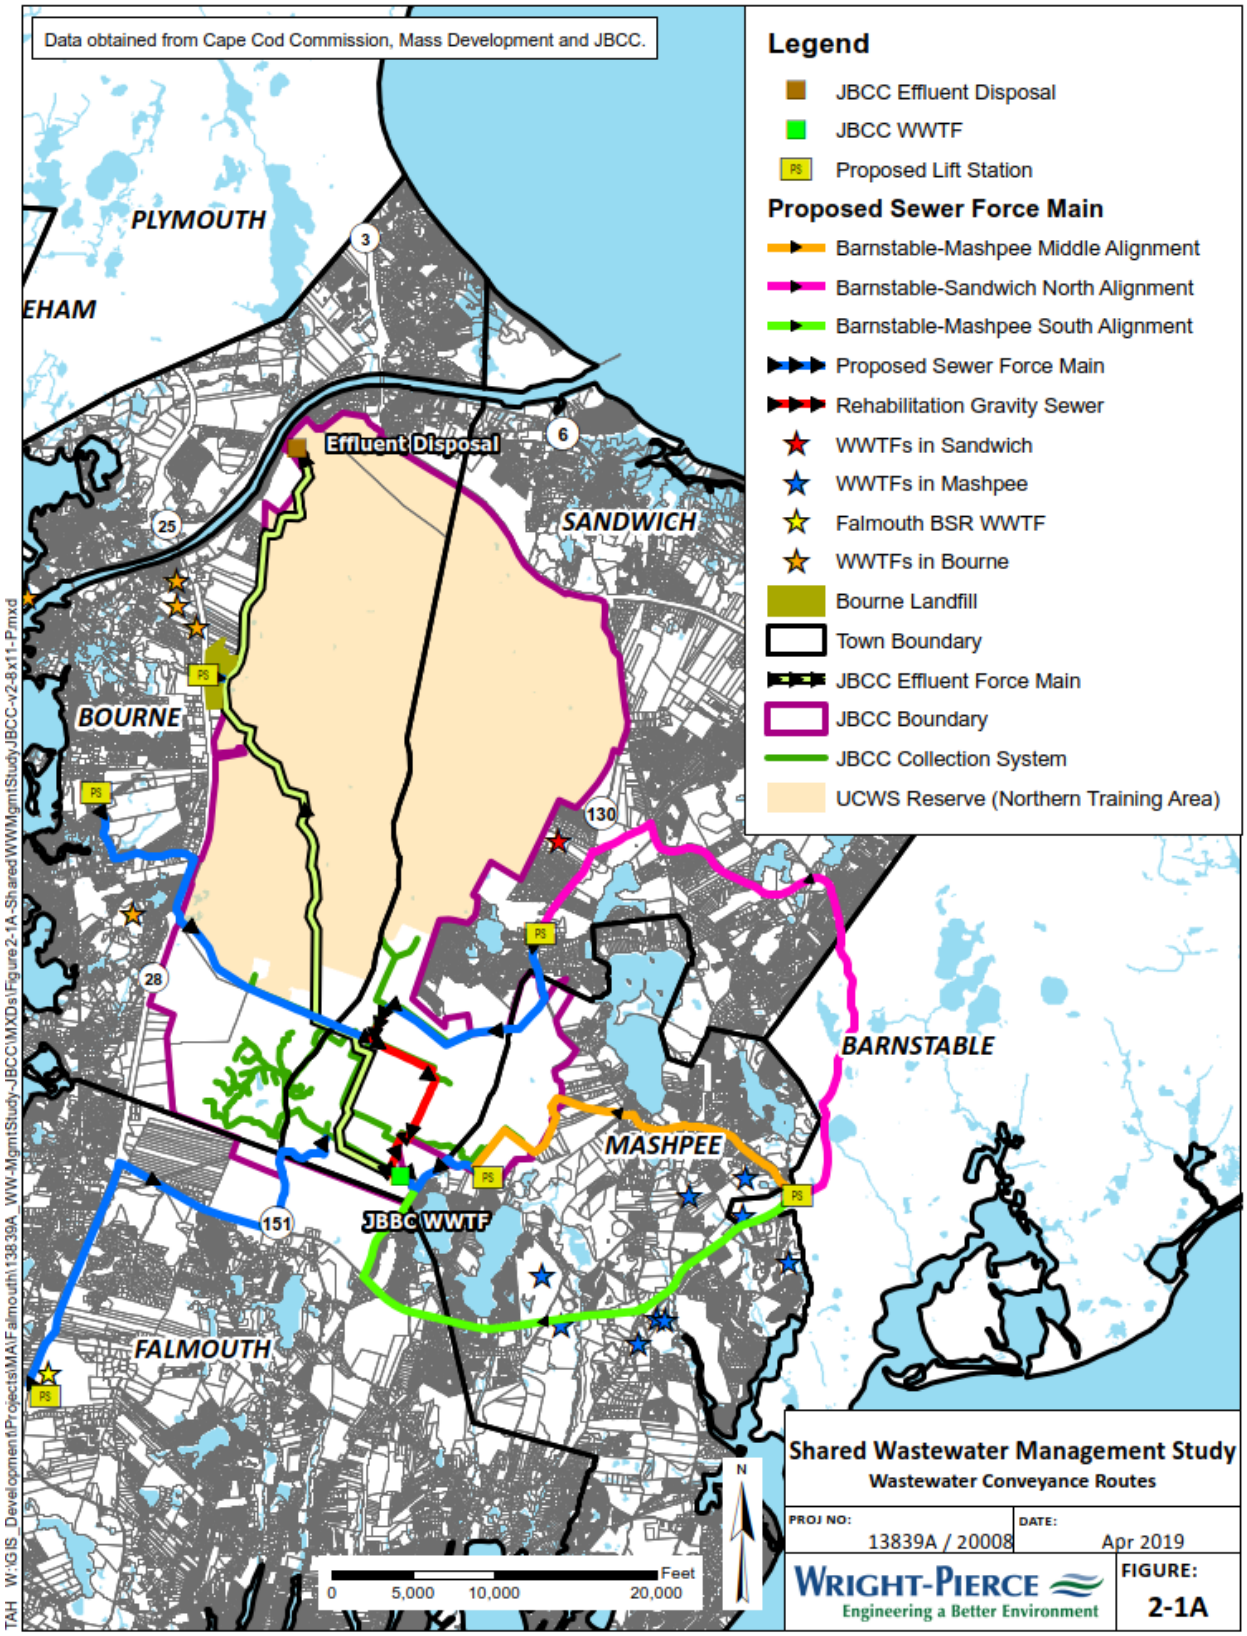
TABLE 3: FORCEMAIN UNIT COSTS

Forcemain Diameter	Route Characteristics		
	Public Way/Dense (Cost/ft)	Public Way/ Less Dense (cost/ft)	Railroad Right of Way (cost/ft)
8-inch	$200	$180	$300
10-inch	$215	$195	$320
12-inch	$230	$210	$340
14-inch	$245	$225	$360
16-inch	$260	$240	$360
18-inch	$280	$250	$380
20-inch	$300	$260	$400

1.2 SUMMARY OF PREFERRED CONVEYANCE OPTIONS

Current preferred conveyance routes are shown on **Figure 2-1A** and identified as follows:

- Bourne North (effluent) – Proposed lift station at ISWM WWTF connected to existing JBCC effluent forcemain, via a new 8" Bourne forcemain.
- Bourne South – Proposed lift station at the intersection of Valley Bars and County Roads to JBCC WWTF via a new 12" Bourne forcemain and rehabilitated gravity sewer (shared with Sandwich).
- Falmouth (effluent) – Proposed lift station at BSR WWTF connected to the JBCC effluent forcemain(s) via a new 18" Falmouth forcemain in Routes 28 and 151.
- Mashpee – Proposed lift station on Back Road Site 1 (Town lot) to JBCC WWTF via new 8" Mashpee forcemain.
- Sandwich – Proposed lift station on portion of Lot-06-236 at 40 Route 130 to JBCC WWTF via 12" Sandwich forcemain, and rehabilitated gravity sewers (shared with Bourne).
- Barnstable – Proposed lift station at intersection of Route 130 and Falmouth Road to JBCC WWTF via a new 20" Barnstable forcemain through Newton Road to a shared Sandwich forcemain and new gravity sewers (shared with Sandwich and Bourne).



Data obtained from Cape Cod Commission, Mass Development and JBCC.

1.3 CONVEYANCE ALIGNMENTS EVALUATED

1.3.1 Bourne Alignments

The following alignments were investigated for Bourne sewage flow from the southern sections of town. This piping is required in the mid-term.

- Option 1. Shortest route through the JBCC base, utilizing existing JBCC gravity sewer
    - 1 large lift station, 1250 gpm, 235 ft TDH, 150 hp
    - 12" forcemain, velocity 3.6 fps, 5.1 miles
    - JBCC rehabilitated gravity sewer, 2.3 miles
    - Total route length: 7.4 miles
    - Advantages
        - Least expensive - by $4.1M
        - Shortest route by 2.1 miles
        - Shortest length within public way / dense route
    - Disadvantages
        - Uncertainty of obtaining construction easements within federal lands for forcemains
        - Uncertainty of the level of rehabilitation required for JBCC gravity sewers
- Option 2A. Route utilizing the Shining Sea bike corridor, 1 lift station
    - 1 large lift station, 1400 gpm, 250 ft TDH, 175 hp
    - 14" forcemain, velocity 3.0 fps, 9.5 miles
    - Total route length, 9.5 miles
- Option 2B. Route utilizing the Shining Sea bike corridor, 2 lift stations
    - 2 large lift stations, 1250 gpm, 175 ft TDH, 100 hp
    - 12" forcemain, velocity 3.6 fps, 9.5 miles
    - Total route length, 9.5 miles
- Option 3A. Route primarily in public way
    - 1 large lift station, 1400 gpm, 250ft TDH, 175 hp

  - 14" forcemain, velocity 3.0 fps, 9.9 miles
  - Total route length, 9.9 miles

- Option 3B. Route primarily in public way
  - 2 large lift stations, 1250 gpm, 175 ft TDH, 120 hp
  - 12" forcemain, velocity 3.6 fps, 9.9 miles
  - Total route length, 9.9 miles

Bourne Option 2A, 2B, 3A and 3B appear to be less favorable option based on the following:

- Advantage
  - Avoids having to obtain extensive construction easements within federal lands for forcemains
  - Avoids concern over the level of rehabilitation required for JBCC gravity sewers
- Disadvantage
  - High costs

One alignment was investigated for Bourne effluent flow from the ISWM WWTF to the JBCC effluent forcemain. We assumed the construction of a medium sized lift station to accommodate long-term conditions.

  - 1 medium lift stations, 570 gpm, 180 ft TDH, 50 hp, Velocity 1.7 fps
  - Existing 8" Forcemain, 100 feet

A summary of the Bourne-South Options is shown below.

TABLE 4: BOURNE CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2A	Option 2B	Option 3A	Option 3B
Cost (2019 Dollars)	$M	10.5	15.2	17.0	16.1	17.8
Rehabilitated JBCC sewer (50% Share)	1000 ft	12.3	0.0	0.0	0.0	0.0
Medium PS (Bourne – North)	Each	1	1	1	1	1
Large PS	Each	1	1	2	1	2
Forcemain - public way/dense	1000 ft	12.7	17.8	17.8	38.5	38.5
Forcemain – public way/ less dense	1000 ft	14.5	32.2	32.2	13.5	13.5

1.3.2 Falmouth Alignments

The following alignments were investigated for Falmouth effluent flow from the BSR WWTF to the JBCC WWTF effluent forcemain. This piping is required in the mid-term.

- Option 1. Route in public way
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 6.7 miles
    - Total route length, 6.7 miles
    - Advantages
        - Least expensive by $100,000
        - Eliminates potentially expensive railroad coordination costs in Option 3
    - Disadvantage
        - Lengthy section of the route is in right of way
- Option 2. Route in public way, with semi-utilization of the Shining Sea bike corridor
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 8.1 miles
    - Total route length. 8.1 miles
    - Advantages
        - Shorter section of the route is in right of way
        - Eliminates potentially expensive railroad coordination costs in Option 3
    - Disadvantage
        - More expensive than Option 1 by $1M
- Option 3. Route in public way and rail right of way
    - 1 Large lift station, 1300 gpm, 220 ft TDH, 150 hp
    - 18" Falmouth effluent forcemain, velocity 1.7 fps, 5.3 miles
    - Total route length, 5.3 miles
    - Advantages
        - Shortest route
        - Potential to be less expensive with favorable railroad coordination costs

- Disadvantages
  - Costs associated with railroad safety and flagmen expenses during construction and regular operation
  - Efficient access to the rail corridor during and after construction
  - Potential damage from vibration caused by rail traffic

A summary of the Falmouth Conveyance Options is shown below.

TABLE 5: FALMOUTH CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2	Option 3
Cost (2019 Dollars)	$M	12.1	13.8	11.8
Large PS	Each	1	1	1
Forcemain - public way/dense	1000 ft	25.9	20.1	13.8
Forcemain - railroad right of way	1000 ft	0.0	0.0	14.2
Forcemain -public way/less dense	1000 ft	9.5	22.6	0.0

1.3.3 Mashpee Alignments

The following alignments were investigated for Mashpee sewage flow to the JBCC WWTF. This piping is required in the short-term.

- Option 1. Mashpee forcemain to connect directly to JBCC WWTF
  - Medium lift station, 560 gpm, 75 ft TDH, 20 hp
  - 8” Dedicated Mashpee forcemain, velocity 3.5 fps, 1.4 miles
  - Total route length: 1.4 miles
  - Advantages
    - Least expensive by $1.7M
    - Shortest forcemain route by 3.4 miles
    - Reduced lift station size
    - Smaller diameter force main
  - Disadvantages
    - None

- Option 2. Mashpee forcemain to shared rehabilitated gravity main with Sandwich and Bourne
    - Medium lift station, 1040 gpm, 140 ft TDH, 70 hp
    - 12" Dedicated Mashpee forcemain, velocity 3.0 fps, 4.2 miles
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 4.8 miles
    - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be cost advantages for Mashpee.
    - Advantages
        - Forcemain would be dedicated to Mashpee and maintaining correct operating conditions would be easier for Mashpee.
        - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be cost advantages for Mashpee.
    - Disadvantages
        - More expensive than Option 1 by $2.4M. (Note: Mashpee Option 3 requires Sandwich to choose Option 2 which is $0.8M more expensive for Sandwich).
- Option 3. Mashpee forcemain to forcemain shared with Sandwich and rehabilitated gravity main shared with Sandwich and Bourne
    - Medium lift station, 1040 gpm, 140 ft TDH, 70 hp
    - 12" Dedicated Mashpee forcemain, velocity 3.0 fps, 2.4 miles
    - 12" S Outer Road forcemain, 0.7 miles, shared with Sandwich
    - 12" Reilly Rd/Grandville Ave forcemain, 1.1 miles, shared with Sandwich
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 4.8 miles

- Advantages
  - If the existing 10-inch JBCC forcemain serving JBCC lift stations at Rocket Storage, Central Heating Plant and Hanger was rehabilitated or decommissioned, there could be additional cost advantages.
- Disadvantages
  - More expensive than Option 1 by $1.7M.

A summary of the Mashpee options is shown below.

TABLE 6: MASHPEE CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2	Option 3
Cost (2019 Dollars)	$M	2.5	5.8	5.0
Rehabilitated JBCC sewer (33% Share)	1000 ft	0	3.4	3.4
Medium PS	Each	1	1	1
Forcemain - public way/dense	1000 ft	7.5	3.0	3.0
Forcemain – public way/less dense	1000 ft	0	18.9	9.7
Forcemain – public way/less dense - 50% share with Sandwich	1000 ft	0	0.0	9.3

1.3.4 Sandwich Alignments

The following alignments were investigated for Sandwich sewage flow to the JBCC WWTF. The conveyance system is required in the mid-term.

- Option 1. Sandwich forcemain to connect to shared rehabilitated gravity main with Bourne
  - Medium lift station, 1050 gpm, 75 ft TDH, 40 hp
  - 12” Dedicated Sandwich forcemain, velocity 3.0 fps, 2.9 miles
  - JBCC rehabilitated gravity sewer, 0.4 miles
  - JBCC rehabilitated gravity sewer, 1.7 miles, shared with Bourne
  - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne
  - Total route length: 5.7 miles
  - Advantages

        - Least expensive by $0.8M
    - Disadvantages
        - Uncertainty of obtaining construction easements within federal lands for forcemains
        - Uncertainty of the level of rehabilitation required for JBCC gravity sewer mains.

- Option 2. Sandwich forcemain to connect shared forcemain with Mashpee (Mashpee Option 2) and shared rehabilitated gravity main with Bourne and Mashpee
    - Medium lift station, 1050 gpm, 140 ft TDH, 60 hp
    - 12" Dedicated Sandwich forcemain, velocity 3.0 fps, 4.2 miles
    - 12" S Outer Road forcemain, 0.7 miles, shared with Mashpee
    - 12" Reilly Rd/Grandville Ave forcemain, 1.1 miles, shared with Mashpee
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne and Sandwich
    - Total route length: 6.6 miles
    - Advantages
        - If Mashpee implements Option 2, there would be cost savings with implementation of Sandwich Option 2.
        - Shortest forcemain route by 0.9 miles
    - Disadvantages
        - More expensive by $0.8M
- Option 3: Sandwich forcemain to connect to Snake Pond Road, then to rehabilitated gravity
    - Medium lift station, 1050 gpm, 105 ft TDH, 60 hp
    - 12" Dedicated Sandwich forcemain, velocity 3.0 fps, 2.4 miles
    - JBCC rehabilitated gravity sewer, 0.4 miles
    - JBCC rehabilitated gravity sewer, 1.7 miles, shared with Bourne
    - JBCC rehabilitated gravity sewer, 0.6 miles, shared with Bourne
    - Total Route length: 5.1 miles
    - Advantages
        - Utilize public way, rather than federal lands
        - Shortest route

- Disadvantages
  - Uncertainty of obtaining construction easements within federal lands for forcemains
  - Uncertainty of the level of rehabilitation required for JBCC gravity sewer mains.

TABLE 7: SANDWICH CONVEYANCE ALTERNATIVES COMPARISON

Conveyance Feature		Option 1	Option 2	Option 3
Cost (2019 Dollars)	$M	5.6	6.9	5.2
Rehabilitated JBCC sewer (100% Share)	1000 ft	2.2	0.0	2.2
Rehabilitated JBCC sewer (50% Share)	1000 ft	12.3	3.4	12.1
Medium PS	Each	1	1	1
Forcemain - public way/dense	1000 ft	3.5	3.5	12.7
Forcemain – public way/less dense	1000 ft	11.9	18.3	0.0
Forcemain – public way/less dense – share with Mashpee	1000 ft	0.0	9.3	0.0

1.3.5 Barnstable Alignments

The following alignments were investigated for Barnstable sewage flow to the JBCC WWTF. Options 1A, 2A and 3A include cost sharing while Options 1B, 2B and 3B do not include cost sharing. Cost sharing is pro-rated based on flow. Barnstable represents 80% of flow when combined with Sandwich and represents 70% of the flow when combined with both Sandwich and Bourne.

- Option 1: Central Alignment through Mashpee
  - 1 very large lift station, 3000 gpm, 70 TDH, 200 hp, located at the intersection of Route 130 and Falmouth Road.
  - 20” forcemain, velocity 3.1 fps, 6.2 miles
    - 2.3 miles on Route 130
    - 0.9 miles on Ashumet Road
    - 1.8 miles on Riley St and Grandville Ave (JBCC roads)

- 1.2 miles shared with Mashpee (19% of total length)

- Advantages
  - Shortest route
  - Potential shared costs with Mashpee
  - Fewer major terrain changes
- Disadvantages
  - Only 19% of route is shared
  - Uncertainty of obtaining construction easements within federal lands for forcemains

- Option 2: Southern Alignment through Mashpee
  - 1 very large lift station, 3000 gpm, 70 TDH, 200 hp, located at the intersection of Route 130 and Falmouth Road.
  - 20" forcemain, velocity 3.1 fps, 7.2 miles
    - 2.3 miles on Falmouth Road (Route 28)
    - 3.4 miles on Nathan Ellis Road (Route 151)
    - 1.2 miles on Sandwich Road
    - 0.3 miles on Simkins Road shared with Mashpee (4% of the route)
  - Advantages
    - Mid-length route
  - Disadvantages
    - Little potential for shared costs (4% of the route is shared with Mashpee)
    - Most of construction route in state highway on areas of high density (Route 28 and Route 151)
    - Terrain requires the installation of at least 6 air release structures.
- Option 3: Northern Alignment through Sandwich
  - 1 large lift station, 3000 gpm, 70 TDH, 300 hp, located at the intersection of Route 130 and Falmouth Road.
  - 20" forcemain, velocity 3.1 fps, 11.6 miles
    - 0.3 miles in Falmouth Road (Route 28)

- 3.7 miles in Santuit/Newtown Rd
- 2.3 miles in Farmersville Rd
- 0.5 miles in Cotuit Road
- 0.5 miles in Quaker Meeting House Road
- 1.3 miles in Route 130
- 3.0 miles shared with Sandwich (21% of the force main route)

- JBCC new gravity sewer, 0.6 miles shared with Sandwich (4% of the total route)
- JBCC new gravity sewer, 2.1 miles shared with Sandwich and Bourne (15% of the total route)
- Total route length: 14.3 miles
- Advantages
  - 40% of total route length is shared
  - Potential shared route with Sandwich and Bourne
  - Most shared cost
- Disadvantages
  - Longest route compared to shortest route by 8 miles.
  - Uncertainty of obtaining construction easements within federal lands for forcemains
  - Uncertainty of the level of rehabilitation or replacement required for JBCC gravity sewer mains.
  - Highest costs

TABLE 8: BARNSTABLE CONVEYANCE ALTERNATIVES COMPARISON WITH COST SHARING

Conveyance Feature – With Shared Casts		Option 1A	Option 2A	Option 3A
Cost (2019 Dollars)	$M	13.9	16.2	25.7
Rehabilitated JBCC sewer (80% Share with Sandwich)	1000 ft	0.0	0.0	3.2
Rehabilitated JBCC sewer (70% Share with Sandwich and Bourne)	1000 ft	0.0	0.0	11.1
Very Large PS	Each	1	1	1
Forcemain - public way/dense	1000 ft	14.3	30.1	31.2
Forcemain – public way/less dense	1000 ft	12.1	6.3	14.3
Forcemain – public way/less dense (80% shared with Sandwich)	1000 ft	0.0	0.0	15.8
Forcemain – public way/less dense (80% shared with Mashpee)	1000 ft	6.4	1.6	0.0

TABLE 9: BARNSTABLE CONVEYANCE ALTERNATIVES COMPARISON WITHOUT COST SHARING

Conveyance Feature – With No Shared Casts		Option 1B	Option 2B	Option 3B
Cost (2019 Dollars)	$M	14.2	16.3	27.7
Rehabilitated JBCC sewer (80% Share with Sandwich)	1000 ft	0.0	0.0	3.2
Rehabilitated JBCC sewer (70% Share with Sandwich and Bourne)	1000 ft	0.0	0.0	11.1
Very Large PS	Each	1	1	1
Forcemain - public way/dense	1000 ft	14.3	30.1	31.2
Forcemain – public way/less dense	1000 ft	12.1	6.3	14.3
Forcemain – public way/less dense (80% shared with Sandwich)	1000 ft	0.0	0.0	15.8
Forcemain – public way/less dense (80% shared with Mashpee)	1000 ft	6.4	1.6	0.0

1.3.6 Effluent Conveyance Systems

The effluent conveyance system will require improvements to accommodate anticipated flow increases in each phase.

- Existing Conveyance System Data

  The existing effluent forcemain will remain in service until dual forcemains and associated pumping capacity are constructed. Characteristics of the existing forcemain are listed below.

  - Existing forcemain
    - 12-inch diameter
    - 10.8 miles
    - Ductile iron
    - Design friction factor, C, 130
    - Distance to high point, 5.8 miles (30,600 feet)
    - Static head: 210 feet
  - Existing system design assumptions
    - Conveyance main operates as a forcemain to the high point and forcemain friction calculations are based on 5.8 miles.
    - From the high point, around 150 feet of head is available to drive flow to the RIB's. A flow of about 1500 gpm uses up the available head.
    - With one pump running at the JBCC WWTF, there is available capacity in the short term for Bourne to discharge treated effluent into the JBCC forcemain at the ISWM.

- Proposed Effluent Forcemains

  In the long-term, the design effluent pumping and conveyance system will be required to handle a flow of approximately 4,000 gpm. The construction of a single large-diameter forcemain will provide increased capacity and valuable redundancy in the event that the 12-inch force main experiences a failure. The construction of the second large-diameter force main will allow the existing 12-inch forcemain to be abandoned or maintained for capacity redundancy. Two alternate routes were identified as outlined below, a match of

the existing route and an alternate route with a lower static head and associated reduced pumping horsepower requirements and related operating costs.

- Proposed 20-inch forcemain (Following existing route)
    - Following existing route (parallel to existing 12-inch forcemain)
    - 20-inch diameter
    - 10.8 miles
    - Distance to high point, 5.8 miles (30,600 feet)
    - Static head: 210 feet
    - 160 HP required for pump station
- Proposed 18-inch forcemains (Alternate route with lower static head)
    - Following improved route with lower static head and TDH
    - 18-inch diameter
    - 10.9 miles
    - Distance to high point, 5.0 miles (26,400 feet)
    - Static head: 95 feet
    - 100 HP required for pump station

1.4 SCHEDULE OF IMPROVEMENTS

1.4.1 Short-term improvements:

- JBCC / All Participants
    - Maintain operation of existing lift station and forcemain
    - Accommodate flows from JBCC and Mashpee arriving at the effluent lift station (252,000 gpd / peaked pump flow of 320 gpm)
- Bourne
    - At the ISWM, install a lift station designed to accommodate mid-term and long-term flows
    - Make connection to existing JBCC forcemain
    - Install additional valves and stubs to make a future connection to new effluent forcemains without disrupting service.
- Falmouth – no changes
- Mashpee
    - Construct Mashpee lift station and forcemain conveying flow to the WWTF.
- Sandwich – no changes
- Barnstable – no changes

1.4.2 Mid-term improvements:

- JBCC / All Participants
    - Maintain operation of existing lift station and forcemain.
    - Accommodate effluent from JBCC, Bourne-South, Mashpee and Sandwich .in the existing effluent forcemain (peaked pump flow of 640 gpm).
    - Construct new 18-inch forcemain from Falmouth connection to the RIB's with interconnection valving with existing 12-inch forcemain.
- Bourne
    - Connect ISWM forcemain into new 18-inch forcemain (peaked flows increase from 87 to 385 gpm).

  - Construct Bourne Option 1 including lift station, forcemain and JBCC gravity sewer rehabilitation.

- Falmouth
  - Construct Falmouth 18-inch forcemain to valving interconnection with existing 12-inch forcemain and new 18-inch forcemain.
  - Direct Falmouth flow to new 18-inch forcemain (peaked pump flow of 444 gpm).
  - Make future provisions for future 18-inch effluent forcemain
- Mashpee – no changes
- Sandwich
  - Construct Sandwich lift station, forcemain and JBCC gravity sewer rehabilitation.

- Barnstable
  - Construct Barnstable lift station, forcemain, and new JBCC gravity sewers.

1.4.3 Long-term improvements

- JBCC / All Participants
  - Construct second 18-inch effluent forcemain and interconnections and connect Bourne and Falmouth to the second forcemain.

JBCC Section 2 Updates

SECTION 2

ENGINEERING ASSESSMENT (UPDATED FOR BARNSTABLE)

2.1 INTRODUCTION

The Town of Barnstable provided capacity requests by wastewater type via email dated March 8, 2019. The text and tables below present the information provided by Barnstable and the updates to the engineering assessment based on these capacity needs.

- Study Basis: The study basis includes a specified amount of sewage from Barnstable will be directed to the JBCC WWTF. For the study basis, the amount of capacity requested is intended to serve the village of Cotuit plus western portions of Barnstable Phases 1, 2 and 3.
- Low End: Same elements, however, for the mid-term, the identified capacity is reduced to just the amount required for Stages 1, 2 and 3 in the Popponesset Bay watershed and, for the long-term, the identified capacity is reduced to just the amount required for the village of Cotuit.
- High End: Same as the study basis, however, for the mid-term, the identified capacity is increased to include western portions of Phases 1 and 2 (for sewage) and, for the long-term, includes effluent flow allocation from the eastern portions of Barnstable following treatment at the Barnstable WPCF.

TABLE 1-7: REQUESTED CAPACITY BY WASTEWATER TYPE

	Capacity Requested – Annual Average Basis		
	Low End (gpd)	Study Basis (gpd)	High End (gpd)
BARNSTABLE			
Short-term (Year 0 to Year 3)			
Sewage Treatment	0	0	0
Effluent Disposal Only	0	0	0
Septage Treatment	0	0	0
Mid-term (Year 5 to Year 20)			
Sewage Treatment	100,000	500,000	800,000
Effluent Disposal Only	0	0	0
Septage Treatment	10,000	10,000	10,000
Long-term (Years 20+)			
Sewage Treatment	500,000	1,200,000	1,200,000
Effluent Disposal Only	0	0	900,000
Septage Treatment	10,000	10,000	10,000

Table 1-8 summarizes the needs of the five towns and JBCC for a 20+-year planning horizon.

The remainder of this section of the report identifies and evaluates the technical factors, costs and management considerations associated with potential shared wastewater facilities at JBCC.

2.2 WASTEWATER FLOWS USED IN THE ENGINEERING ASSESSMENT

Different components of a wastewater system are designed based on different process conditions (e.g., minimum day, annual average, maximum month, maximum multi-day, maximum day and peak instantaneous, etc.). In the absence of existing data on short-term peak flows, peaking factors are typically utilized to establish the other conditions. For the purposes of this study:

- Sewage peaking factors were established using the TR-16 Guides for the Design of Wastewater Treatment Works curves entitled "Relation of Extreme Discharges on Maximum and Minimum Days to the Average Daily Discharge of Domestic Sewage" (New England Interstate Water Pollution Control Commission, 2016) and were adjusted upward by 0.2 to account for seasonal population/flow variations on Cape Cod. Septage peaking factors were set assuming that equalization tanks would be provided.
- Effluent-only peaking factors were estimated by assuming that the remote facilities (i.e., Falmouth's Blacksmith Shop Road WWTF and Bourne's anticipated future Integrated Solid Waste Management Facility Leachate WWTF) have, or will have, effluent equalization tanks sized to meet these peaking factor limitations or will utilize existing or new effluent disposal systems local to the ISWM and BSR WWTFs to manage peak flows.

Table 2-1 summarizes the peaking factors which have been used for this project. The peaking factors from **Table 2-1** were applied to the annual average flows from **Table 1-8** in order to establish the wastewater flows that will be used for this engineering assessment. **Table 2-2** summarizes the annual average, maximum 3-day flows and the peak conveyance flows for the existing, short-term, mid-term and long-term conditions. The flows in **Table 2-2** have been used for the conceptual sizing and costing of proposed wastewater system components.

TABLE 1-8: SUMMARY OF CAPACITY REQUESTS TO BE USED IN ENGINEERING ASSESSMENT

	Capacity Requested - Annual Average Flows (gpd)								
	JBCC	**Bourne**	**Falmouth**	**Mashpee**	**Sandwich**	**Barnstable**	**Total**	**Capacity Provided**	**% Increase Existing Capacity**

Effluent Disposal Only	0	444,000	490,000	0	0	0	934,000		
Effluent Disposal	147,000	714,000	512,000	203,000	110,000	510,000	2,196,000	**2,200,000**	511%
Long-Term (20 year)									
Sewage Treatment	147,000	456,000	0	200,000	340,000	1,200,000	2,343,000	**2,400,000**	567%
Septage Treatment	0	11,000	22,000	3,000	10,000	10,000	56,000		
Effluent Disposal Only	0	651,000	1,490,000	0	0	0	2,141,000		
Effluent Disposal	147,000	1,118,000	1,512,000	203,000	350,000	1,210,000	4,540,000	**4,550,000**	1164%
Notes	1	1	1	1	1			2, 4	3

1) Refer to Table 1-7 for additional information.

2) Existing Capacity based on WP 2014, GWDP and WWTF O&M.

3) Capacity for Short-Term, Mid-Term and Long-Term conditions are increases over the existing capacity.

4) Organic loading treatment capacity will need to account for concentrated nature of septage.

TABLE 2-1: PEAKING FACTORS FOR MIMIMUM AND MAXIMUM FLOW CONDITIONS

Ratio to Annual Average	Sewage	Septage	Effluent Only
Minimum Day	0.40	0.50	0.50
Minimum Month	0.75	0.75	0.75
Annual Average	1.00	1.00	1.00
Maximum Month	1.25	1.50	1.25
Maximum 3-Day	2.2 (LT) to 2.7 (ST)	1.75	1.25
Peak Instantaneous	3.5 (LT) to 4.7 (ST)	1.75	1.25

Note: LT = Long term; ST = Short term

TABLE 2-2: EFFLUENT DISPOSAL FLOWS USED IN ENGINEERING ASSESSMENT

Flows in gpd	Annual Average	Maximum 3-Day	Peak Conveyance
Existing	140,000	386,000	1,400,000
Short-Term	460,000	1,080,000	1,750,000
Mid-Term	2,200,000	4,160,000	6,090,000
Long-Term	4,550,000	7,930,000	10,980,000

Note: Refer to Appendix A for a breakdown of flows by category. Rounded to nearest 10,000 gpd

2.3 IDENTIFICATION OF FUTURE WASTEWATER SYSTEM COMPONENTS

This section identifies the components of the future wastewater system to address future wastewater needs at shared facilities. The analysis and costs are presented in these categories.

2.3.1 Conveyance

Each community will have a collection system that transports flow to the location of the regional conveyance facilities. This report addresses the conveyance system costs but will not address the collection system costs.

2.3.2 Treatment

The JBCC WWTF will require upgrade/replacement to serve the regional needs. This report considers the costs for WWTF upgrade/replacement at the current WWTF location or at the former WWTF location (immediately adjacent to the current location). Any potential future WWTF expansions to include more regional flow and/or regional biosolids processing and/or regional source separated organics digestion is beyond the scope of this study.

2.3.3 Transport to Effluent Disposal

WWTF effluent is conveyed to the existing RIBs via the existing 11-mile long, 12-inch diameter forcemain. This report considers the costs for upgrades to this forcemain as well as supplemental forcemain(s) to the supplemental or replacement effluent disposal methods.

2.3.4 Effluent Disposal

The JBCC RIBs will need to be supplemented or replaced in order to serve the regional needs. This report considers the costs for additional RIBs as well as other supplemental/replacement effluent disposal methods.

2.4 CONVEYANCE

This section identifies the options for wastewater conveyance systems required to support shared wastewater management opportunities for Bourne, Falmouth, Mashpee, Sandwich, Barnstable and JBCC. The objectives of the conveyance study include the following:

- Identify alignments for conveyance of sewage from Bourne's southern section, Mashpee, Sandwich and Barnstable to the JBCC WWTF for treatment and disposal;
- Identify alignments for conveyance of treated wastewater ("effluent") from the JBCC WWTF, the Bourne ISWM WWTF and the Falmouth BSR WWTF to the JBCC treated effluent conveyance system and disposal areas;
- Identify rehabilitation of sections of the JBCC gravity sewer system where shorter alignments and capital cost savings are available;
- Review conceptual profiles of each force main alignment to evaluate conceptual static and dynamic head on the pumping system;
- Develop preliminary hydraulic calculations to determine conceptual forcemain sizes; and
- Determine conceptual number and size of required pump stations.

2.4.1 Concept Design Criteria

No revised information (refer to 2017 Report).

2.4.2 Summary of Preferred Conveyance Options

No revised information (refer to 2017 Report).

2.4.2.1 Preferred Bourne Alignment Details

2.4.2.2 Preferred Falmouth Alignment Details

2.4.2.3 Preferred Mashpee Alignment Details

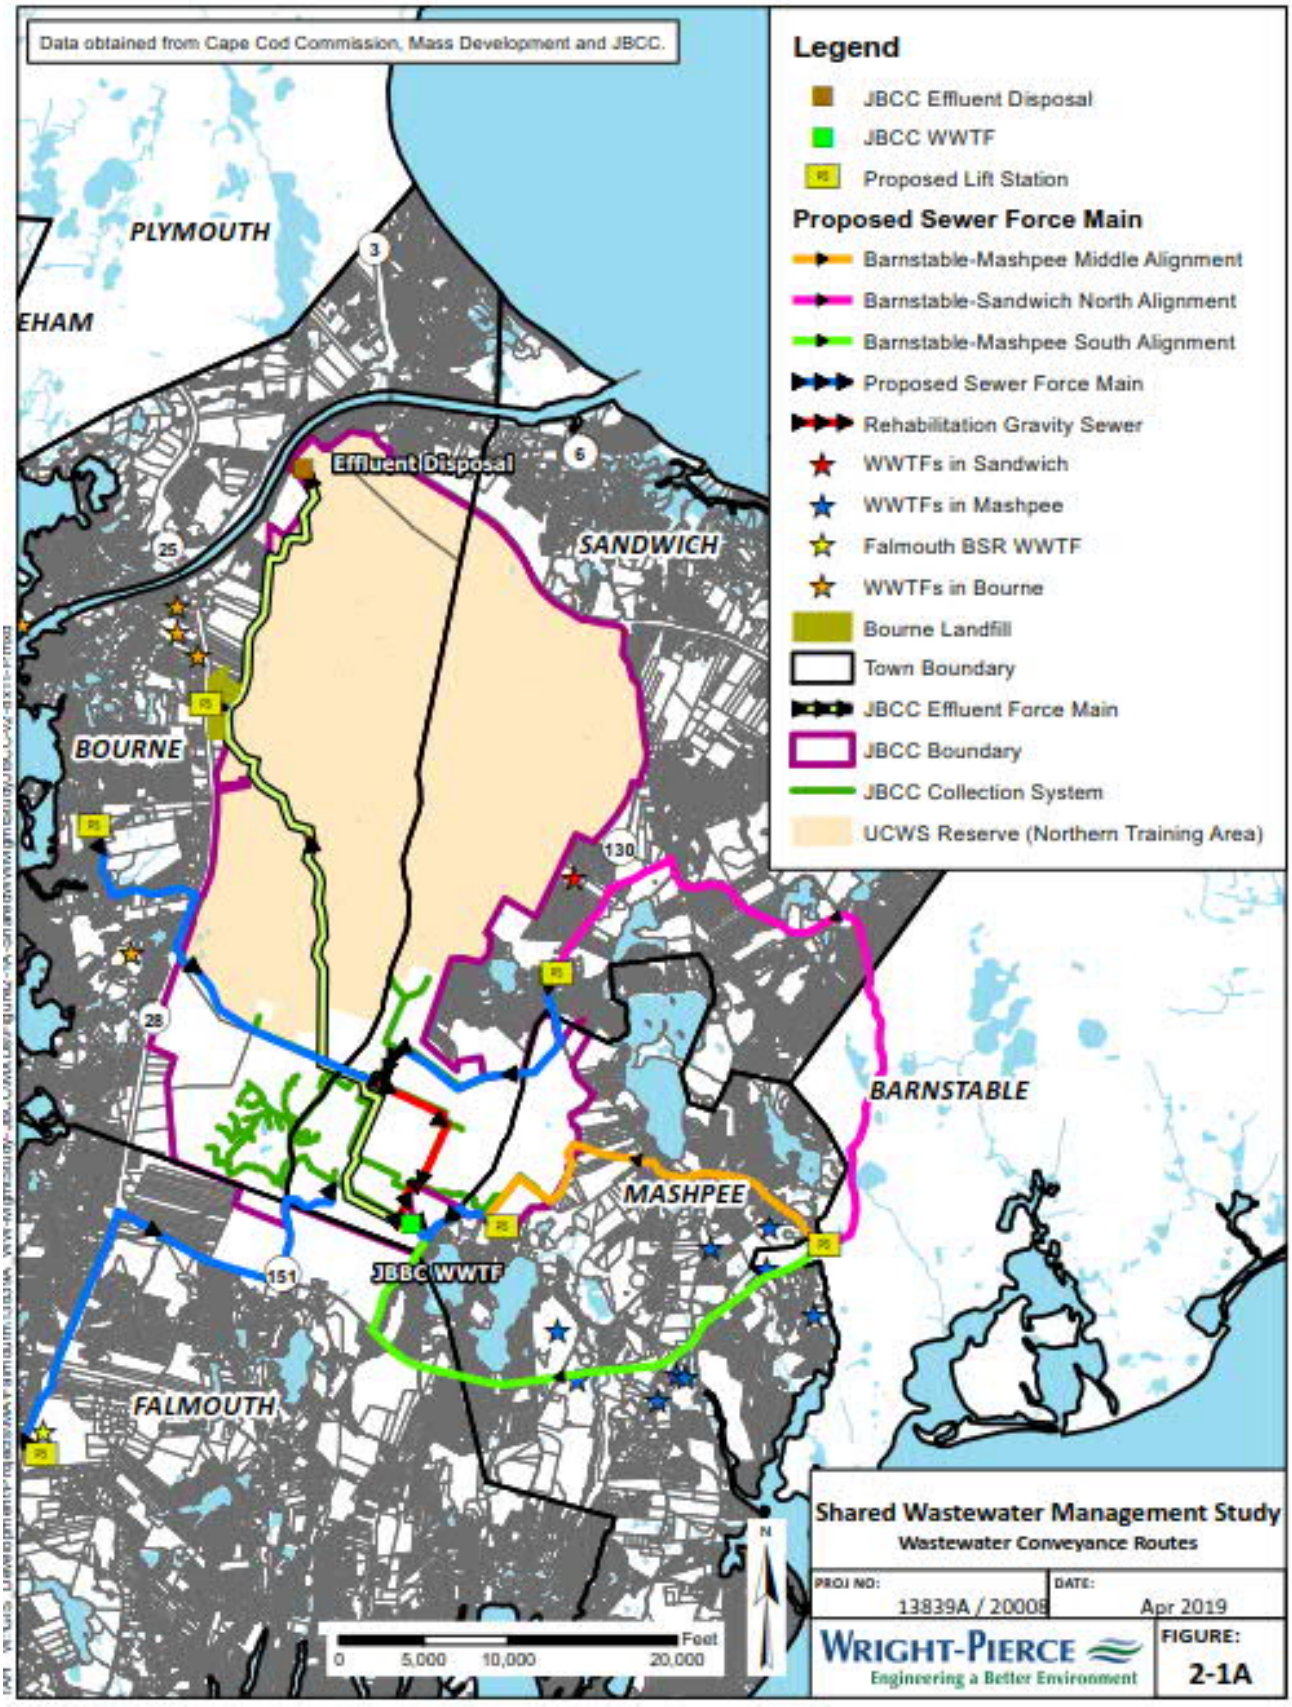
2.4.2.4 Preferred Sandwich Alignment Details

2.4.2.5 Preferred Barnstable Alignment Details

Three candidate alignments were identified by the Town via email dated March 15, 2019. These alignments consist of a central alignment through Mashpee (Option 1), a southern alignment through Mashpee (Option 2) and a northern alignment through Sandwich (Option 3). Refer to **Figure 2-1A** for locations of these alignments. The cost basis, advantages, and disadvantages of each alignment are described in a memorandum entitled *"JBCC Shared Wastewater Management Study, Evaluation of Conveyance Options"* (Wright-Pierce, May 13, 2019). A summary of the costs presented in that memorandum is tabulated below.

ENR CCI 11228, April 2019	Conceptual Cost without Cost Sharing	Conceptual Cost with Cost Sharing, Pro-Rata based on Flow
Option 1 – Central Alignment	$14.2M	$13.9M
Option 2 – Southern Alignment	$16.3M	$16.2M
Option 3 – Northern Alignment	$27.7M	$25.7M

Option 3 is carried forward in the costs presented herein (at a placeholder value of $25M) because it is the highest cost and most conservative of the three alignments.



Data obtained from Cape Cod Commission, Mass Development and JBCC.

2.5 TREATMENT

No revised information (refer to 2017 Report).

2.6 TRANSPORT TO EFFLUENT DISPOSAL

No revised information (refer to 2017 Report).

2.7 EFFLUENT DISPOSAL

No revised information (refer to 2017 Report).

2.8 IDENTIFICATION OF COMPOSITE ALTERNATIVES

This section identifies and describes the following alternatives for the treatment and disposal aspects of the future wastewater system:

1) New WWTF with RIBs
2) New WWTF with RIBs and Wicks
3) New WWTF with RIBs and Deep Well Injection
4) New WWTF with RIBs and Canal Outfall
5) New WWTF with Deep Well Injection
6) New WWTF with Canal Outfall

Treatment process schematics for each alternative are shown on **Figure 2-4A**. Each of the alternatives includes limited upgrades to the existing JBCC wastewater facilities in order to maintain permit compliance and capacity in the short-term. All flow rates indicated in Section 2.8 reference the 3-day peak flow for the long term. Each of the alternatives includes a description of the anticipated phasing requirements. A summary of the upgraded and new facilities for each of the composite alternatives is presented on the following pages. The project phasing and management entity boundaries which are included in the planning-level cost estimates are shown on **Figure 2-5A**.

2.8.1 New WWTF with RIBs

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Long-Term: • New ENR/SBR WWTF plus disinfection. • 16 new RIBs on the adjacent US Government parcel (ACOE) or in the Reserve to achieve an additional 6.38-mgd capacity. • 2 new effluent forcemains (11.0 miles) located parallel to existing (3 total forcemains). • Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.8.2 New WWTF with RIBs and Wicks

Short-Term: • Upgrades to existing JBCC wastewater facilities. • Upgrades to existing RIBs to achieve 1.55-mgd capacity. • Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).
Long-Term: • New ENR/SBR WWTF plus sand filtration and disinfection. • Assume that Bourne ISWM WWTF and Falmouth BSR WWTF can meet the effluent TSS and turbidity requirements for wicks (i.e., no cost included herein). • 30 to 65 new wicks to achieve an additional 6.38-mgd capacity (63 based on 100,000 gpd per wick). • 2 new effluent forcemains (11.0 miles) located parallel to existing (3 total forcemains). • Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.8.3 New WWTF with RIBs and Deep Well Injection

Short-Term:

- Upgrades to existing JBCC wastewater facilities.
- Upgrades to existing RIBs to achieve 1.55-mgd capacity.
- Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).

Long-Term:

- New ENR/MBR WWTF plus RO/Storage and disinfection.
- 8 to 10 new DWI wells in the Cantonment or the Reserve to achieve an additional 6.38-mgd capacity (9 based on 750,000 gpd per DWI well).
- Add RIBs or wicks to serve as reserve disposal (1.55 mgd)
- 2 new effluent forcemains (2.3 miles) located parallel to existing (3 total forcemains).
- Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.8.4 New WWTF with RIBs and Canal Outfall

Short-Term:

- Upgrades to existing JBCC wastewater facilities.
- Upgrades to existing RIBs to achieve 1.55-mgd capacity.
- Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).

Long-Term:

- New ENR/SBR WWTF plus disinfection.
- Assume that Falmouth BSR WWTF and Bourne ISWM WWTF can meet the effluent requirements for a Canal outfall (i.e., no cost included herein).
- New Canal outfall sized for an additional 6.38-mgd capacity.
- 2 new effluent forcemains (11.5 miles) located parallel to existing (3 total forcemains).
- Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.8.5 New WWTF with Deep Well Injection

Short-Term:
- Upgrades to existing JBCC wastewater facilities.
- Upgrades to existing RIBs to achieve 1.55-mgd capacity. Maintain existing RIBs to serve as reserve disposal.
- Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).

Long-Term:
- New ENR/MBR WWTF plus RO/Storage and disinfection. All Falmouth and Bourne effluent flow brought to JBCC WWTF site.
- 10 to 12 new DWI wells in the Cantonment to achieve an additional 7.93-mgd capacity (11 based on 750,000 gpd per DWI well).
- 2 new effluent forcemains (2.3 miles) located parallel to existing (3 total forcemains).
- Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.8.6 New WWTF with Canal Outfall

Short-Term:
- Upgrades to existing JBCC wastewater facilities.
- Upgrades to existing RIBs to achieve 1.55-mgd capacity.
- Maintain existing RIBs to serve as reserve disposal.
- Connect Bourne ISWM WWTF (effluent) and Mashpee (sewage).

Long-Term:
- New ENR/SBR WWTF plus UV disinfection.
- Assume that Bourne ISWM WWTF and Falmouth BSR WWTF can meet the effluent requirements for a Canal outfall (i.e., no cost included herein).
- New Canal outfall sized for an additional 7.93-mgd capacity.
- 2 new effluent forcemains (11.5 miles) located parallel to existing (3 total forcemains).
- Connect Falmouth BSR WWTF (effluent); Bourne, Sandwich and Barnstable (sewage).

2.9 EVALUATION OF COMPOSITE ALTERNATIVES

The cost information presented herein is in **November 2017 dollars** and is based on ENR Index 10800. Planning-level cost estimates for the long-term flows are summarized in **Table 2-5** (without Barnstable) and **Table 2-5A** (with Barnstable).

2.9.1 Planning-Level Capital Costs

Planning-level capital cost estimates were developed using cost estimating procedures consistent with industry standards utilizing concept layouts, unit cost information, and planning-level cost curves, as necessary. The capital costs include the following key components: wastewater collection, transport-to-treatment, wastewater treatment, transport-to-disposal, effluent disposal, land acquisition, and technical services and contingencies. Key technical data were compiled for all plans, based on conceptual designs. Next, typical "unit costs" were applied (e.g., dollars per foot of pipe, or dollars per pump station) using recent experience from publicly-bid wastewater projects across New England. Unit costs for "baseline" treatment and disposal facilities (i.e., ENR/SBR and disinfection) were taken from the Barnstable County Cost Report ("*Comparison of Costs for Wastewater Management Systems Applicable to Cape Cod*", April 2010). Once basic construction costs were estimated, allowances were added for contingencies and technical services (40% of construction subtotal) and financing/legal/administration expenses (3% of construction subtotal). Land costs were excluded from this analysis.

2.9.2 Planning-Level Operation and Maintenance Costs

Annual operation and maintenance (O&M) costs were developed for each plan for the purposes of comparison among the plans. These planning-level O&M costs were developed using the anticipated wastewater flow rates for each plan. Unit O&M costs were taken from the Barnstable County Cost Report (April 2014). These O&M estimated include the following types of expenses: labor, including fringe benefits; electrical energy for powering pumps and treatment equipment; fuel for building heating and vehicular use; chemicals; disposal of dewatered sludge; laboratory testing and other permit compliance costs; administrative costs such as insurance; and equipment maintenance and replacement.

2.9.3 Equivalent Annual Cost

The “equivalent annual cost" (EAC) is a standard economic tool that allows for the calculation of a single "cost" to represent the combination of capital costs and annual expenses for O&M. The equivalent annual cost is the sum of the annual O&M cost plus the annualized debt service on the capital costs. For the purposes of this study, the present worth has been computed assuming a 2% interest rate and a 20-year loan based on presumed DEP CWSRF (Clean Water State Revolving Fund) loan financing.

2.9.4 Considerations for Composite Alternatives

No revised information

2.9.5 Evaluative Criteria

No revised information. **Table 2-6** was not updated or included herein.

2.9.6 Cost Breakdown by Phase

Option 6 (Outfall) was selected because it is the most conservative (i.e., most expensive) of the four composite alternatives that have relatively equivalent cost (i.e., Options 1, 2, 4 and 6). The cost breakdown is provided as follows:

- Short-Term Costs – These costs consist of the items identified in Section 1.4 of this report as well as the conveyance costs for Bourne ISWM WWTF and Mashpee sewage.
- Long-Term Costs – These costs consist of the remainder of the treatment, transport to disposal and disposal costs necessary to provide the requested capacity for the “study basis” flows.

The cost breakdown by phase is presented in **Table 2-7**. Additional information is provided in **Appendix A**.

2.9.7 Cost Allocation Among Participants

Costs for the various wastewater system components were allocated in the following ways:

- Conveyance – Costs were attributed to the individual towns, except where new or rehabilitated infrastructure is shared and except for baseline inflow removal at JBCC. When shared, the costs are split on a pro-rata flow basis among affected individual towns. None of the conveyance costs were attributed to JBCC. Inflow removal costs associated with the existing system are the responsibility of JBCC. Conveyance costs include the cost of the lift station to convey flow to the JBCC system.
- Transport and Disposal – Costs were attributed to the individual towns and JBCC on a pro-rata flow basis, in accordance with the requested effluent disposal capacity indicated in Section 1.
- Contingency/Technical/Legal/Administration/Finance – Costs were attributed to the individual towns and JBCC pro-rata based on the subtotal of the planning-level construction costs.

The percentage of total effluent flow by phase is presented in Table 2-8. These percentages are used to allocate O&M costs. The basis for allocation of capital costs is presented in Table 2-9. This allocation was used for the mid-term and long-term conditions. The allocations of capital cost, annual O&M, and equivalent cost are presented in Table 2-10, Table 2-11 and Table 2-12, respectively. Additional information is presented in Appendix A.

It is important to note that cost allocations per entity will change if not all entities ultimately elect to participate or if entities elect to participate at higher or lower flow rates than indicated in Section 1 of this report. Cost allocations will also change if different allocation assumptions are utilized.

2.9.8 Comparison of Costs to Previous Town Planning Documents

No revised information.

TABLE 2-5: SUMMARY OF PLANNING-LEVEL COST ESTIMATES AND COST ALLOCATION (BASED ON LONG-TERM, CONSTRUCTED AS A SINGLE PROJECT) (ENR CCI 11228, April 2019)

Option	1	2	3	4	5	6
Description of Effluent Disposal	**RIB**	**RIB & Wicks**	**RIB & DWI**	**RIB & Outfall**	**DWI**	**Outfall**
Capital Cost						
Construction - Conveyance	$29,030,000	$29,030,000	$29,030,000	$29,030,000	$29,030,000	$29,030,000
Construction - Treatment	$38,900,000	$41,300,000	$66,100,000	$41,300,000	$72,700,000	$41,300,000
Construction - Transport to Disposal	$22,900,000	$22,900,000	$5,160,000	$23,950,000	$5,160,000	$23,950,000

TABLE 2-10: CAPITAL COST ALLOCATION (ENR CCI 11228, April 2019)

	Short-Term	**Long-Term w/o Barnstable**	**Long-Term w/ Barnstable**
JBCC	$1.5M	$10.8M	$8.7M
Bourne	$1.8M	$54.1M	$45.6M
Falmouth	$0M	$41.5M	$37.0M
Mashpee	$5.6M	$18.4M	$15.5M
Sandwich	$0M	$29.2M	$24.2M
Barnstable	$0M	$0M	$98.0M
Total	$8.9M	$154.0M	$229.0M

Note:
1) For the illustrative purposes, costs are allocated pro-rata based on flow, as described in Section 2.9.7.

TABLE 2-11: ANNUAL O&M ALLOCATION (ENR CCI 11228, April 2019)

	Short-Term	Long-Term w/o Barnstable	Long-Term w/ Barnstable
JBCC	$0.49M	$0.26M	$0.22M
Bourne	$0.33M	$1.14M	$1.02M
Falmouth	$0.00M	$0.74M	$0.79M
Mashpee	$0.66M	$0.36M	$0.30M
Sandwich	$0.00M	$0.62M	$0.52M
Barnstable	$0.00M	$0.00M	$1.77M
Total	$1.48M	$3.12M	$4.62M

Note:
1) For the illustrative purposes, costs are allocated pro-rata based on flow, as described in Section 2.9.7.
2) This table includes asset management, capital improvements and management entity administrative costs associated with the take-over of the existing JBCC wastewater systems.

TABLE 2-12: EQUIV. ANNUAL COST ALLOCATION (ENR CCI 11228, April 2019)

	Short-Term	Long-Term w/o Barnstable	Long-Term w/ Barnstable
JBCC	$0.58M	$0.83M	$0.65M
Bourne	$0.44M	$4.33M	$3.70M
Falmouth	$0.00M	$3.28M	$3.06M
Mashpee	$1.00M	$1.14M	$0.90M
Sandwich	$0.00M	$2.41M	$2.00M
Barnstable	$0.00M	$0.00M	$7.77M
Total	$2.02M	$11.99M	$18.08M

Note:
1) For the illustrative purposes, costs are allocated pro-rata based on flow, as described in Section 2.9.7.
2) Annual debt services on capital costs is calculated based on a CWSRF at 2% interest for 20 years (CRF 16.35).
3) This table includes asset management, capital improvements and management entity administrative costs associated with the take-over of the existing JBCC wastewater systems.

Based on the equivalent annual cost allocation presented in **Table 2-13**, each town and JBCC would have a reduction in equivalent annual cost if Barnstable were to participate. The amount of the reduction ranges from 21% to 27% for JBCC, Mashpee and Sandwich (sewage users), to 17% for Bourne (sewage and effluent user) to 7% for Falmouth (effluent user). Note that the additional costs for JBCC wastewater system, asset management, capital improvements and management entity administrative cost allowances would need to be allocated among the participants.

TABLE 2-5: SUMMARY OF PLANNING-LEVEL COST ESTIMATES AND COST ALLOCATION (BASED ON LONG-TERM, CONSTRUCTED AS A SINGLE PROJECT) (ENR CCI 11228, April 2019)

Option	**1**	**2**	**3**	**4**	**5**	**6**
Description of Effluent Disposal	**RIB**	**RIB & Wicks**	**RIB & DWI**	**RIB & Outfall**	**DWI**	**Outfall**
Capital Cost						
Construction - Conveyance	$29,030,000	$29,030,000	$29,030,000	$29,030,000	$29,030,000	$29,030,000
Construction - Treatment	$38,900,000	$41,300,000	$66,100,000	$41,300,000	$72,700,000	$41,300,000
Construction - Transport to Disposal	$22,900,000	$22,900,000	$5,160,000	$23,950,000	$5,160,000	$23,950,000
Construction - Disposal	$11,700,000	$11,400,000	$13,400,000	$11,900,000	$14,200,000	$13,400,000
Contingency, Technical, Legal/Admin/Finance	$44,090,000	$44,990,000	$48,890,000	$45,660,000	$52,070,000	$46,300,000
Total Capital Cost	**$146,620,000**	**$149,620,000**	**$162,580,000**	**$151,840,000**	**$173,160,000**	**$153,980,000**
Ratio to Lowest - Total Capital Cost	1.00	1.02	1.11	1.04	1.18	1.05
Ratio to Lowest - Capital Cost, excl. Conveyance	1.00	1.03	1.15	1.05	1.25	1.07
Annual Operation & Maintenance Cost	**$2,910,000**	**$3,010,000**	**$6,040,000**	**$3,110,000**	**$7,300,000**	**$3,110,000**
Ratio to Lowest - Annual O&M	1.00	1.03	2.08	1.07	2.51	1.07
Total Annual Debt Service on Capital Cost	$8,970,000	$9,150,000	$9,940,000	$9,290,000	$10,590,000	$9,420,000
Total Equivalent Annual Cost (Note 3)	**$11,880,000**	**$12,160,000**	**$15,980,000**	**$12,400,000**	**$17,890,000**	**$12,530,000**
Ratio to Lowest - Equivalent Annual Cost	1.00	1.02	1.35	1.04	1.51	1.05
EAC per thousand gallons of disposal capacity	$9.72	$9.94	$13.07	$10.14	$14.63	$10.25

Notes:

1) Costs are presented in current dollars based on Engineering News Record Construction Cost Index 11228 (April 2019).
2) Refer to Appendix A for supporting information.
3) Equivalent Annual Cost equals Annual O&M Cost plus the Annual Debt Service on Capital Cost.
4) Allocation for Conveyance is 100% to each town. Allocation for treatment/transport/disposal is pro-rated based on flow capacity requested.
5) Blue indicates lowest cost option, green indicates second lowest cost option and orange indicates third lowest cost option.

STEP 3A

TABLE 2-5: SUMMARY OF PLANNING-LEVEL COST ESTIMATES AND COST ALLOCATION (BASED ON LONG-TERM, CONSTRUCTED AS A SINGLE PROJECT) (ENR CCI 11228, April 2019)

Option	**1**	**2**	**3**	**4**	**5**	**6**
Description of Effluent Disposal	**RIB**	**RIB & Wicks**	**RIB & DWI**	**RIB & Outfall**	**DWI**	**Outfall**
Capital Cost						
Construction - Conveyance	$27,700,000	$27,700,000	$27,700,000	$27,700,000	$27,700,000	$27,700,000
Construction - Treatment	$38,900,000	$41,300,000	$66,100,000	$41,300,000	$72,700,000	$41,300,000
Construction - Transport to Disposal	$22,900,000	$22,900,000	$5,160,000	$23,950,000	$5,160,000	$23,950,000
Construction - Disposal	$11,700,000	$11,400,000	$13,400,000	$11,900,000	$14,200,000	$13,400,000
Contingency, Technical, Legal/Admin/Finance	$43,520,000	$44,420,000	$48,310,000	$45,090,000	$51,500,000	$45,730,000
Total Capital Cost	**$144,720,000**	**$147,720,000**	**$160,670,000**	**$149,940,000**	**$171,260,000**	**$152,080,000**
Ratio to Lowest - Total Capital Cost	1.00	1.02	1.11	1.04	1.18	1.05
Ratio to Lowest - Capital Cost, excl. Conveyance	1.00	1.03	1.15	1.05	1.25	1.07
Annual Operation & Maintenance Cost	**$2,910,000**	**$3,010,000**	**$6,040,000**	**$3,110,000**	**$7,300,000**	**$3,110,000**
Ratio to Lowest - Annual O&M	1.00	1.03	2.08	1.07	2.51	1.07
Total Annual Debt Service on Capital Cost	$8,850,000	$9,030,000	$9,830,000	$9,170,000	$10,470,000	$9,300,000
Total Equivalent Annual Cost (Note 3)	**$11,760,000**	**$12,040,000**	**$15,870,000**	**$12,280,000**	**$17,770,000**	**$12,410,000**
Ratio to Lowest - Equivalent Annual Cost	1.00	1.02	1.35	1.04	1.51	1.06
EAC per thousand gallons of disposal capacity	$9.62	$9.85	$12.98	$10.04	$14.53	$10.15

Notes:

1) Costs are presented in current dollars based on Engineering News Record Construction Cost Index 11228 (April 2019).
2) Refer to Appendix A for supporting information.
3) Equivalent Annual Cost equals Annual O&M Cost plus the Annual Debt Service on Capital Cost.
4) Allocation for Conveyance is 100% to each town. Allocation for treatment/transport/disposal is pro-rated based on flow capacity requested.
5) Blue indicates lowest cost option, green indicates second lowest cost option and orange indicates third lowest cost option.

TABLE 2-5: SUMMARY OF PLANNING-LEVEL COST ESTIMATES AND COST ALLOCATION (BASED ON LONG-TERM, CONSTRUCTED AS A SINGLE PROJECT) (ENR CCI 11228, April 2019)

Option	1	2	3	4	5	6
Description of Effluent Disposal	**RIB**	**RIB & Wicks**	**RIB & DWI**	**RIB & Outfall**	**DWI**	**Outfall**
Capital Cost						
Construction - Conveyance	$56,730,000	$56,730,000	$56,730,000	$56,730,000	$56,730,000	$56,730,000
Construction - Treatment	$58,000,000	$61,700,000	$92,800,000	$61,700,000	$98,800,000	$61,700,000
Construction - Transport to Disposal	$25,720,000	$25,720,000	$5,760,000	$26,910,000	$5,760,000	$26,910,000
Construction - Disposal	$13,200,000	$12,900,000	$16,600,000	$13,400,000	$18,400,000	$14,800,000
Contingency, Technical, Legal/Admin/Finance	$66,070,000	$67,530,000	$73,910,000	$68,260,000	$77,270,000	$68,860,000
Total Capital Cost	**$219,720,000**	**$224,580,000**	**$245,800,000**	**$227,000,000**	**$256,960,000**	**$229,000,000**
Ratio to Lowest - Total Capital Cost	1.00	1.02	1.12	1.03	1.17	1.04
Ratio to Lowest - Capital Cost, excl. Conveyance	1.00	1.04	1.19	1.05	1.27	1.07
Annual Operation & Maintenance Cost	**$4,290,000**	**$4,450,000**	**$7,100,000**	**$4,620,000**	**$8,150,000**	**$4,620,000**
Ratio to Lowest - Annual O&M	1.00	1.04	1.66	1.08	1.90	1.08
Total Annual Debt Service on Capital Cost	$13,440,000	$13,730,000	$15,030,000	$13,880,000	$15,710,000	$14,000,000
Total Equivalent Annual Cost (Note 3)	**$17,730,000**	**$18,180,000**	**$22,130,000**	**$18,500,000**	**$23,860,000**	**$18,620,000**
Ratio to Lowest - Equivalent Annual Cost	1.00	1.03	1.25	1.04	1.35	1.05
EAC per thousand gallons of disposal capacity	$14.50	$14.87	$18.10	$15.13	$19.51	$15.23

Notes:

1) Costs are presented in current dollars based on Engineering News Record Construction Cost Index 11228 (April 2019).
2) Refer to Appendix A for supporting information.
3) Equivalent Annual Cost equals Annual O&M Cost plus the Annual Debt Service on Capital Cost.
4) Allocation for Conveyance is 100% to each town. Allocation for treatment/transport/disposal is pro-rated based on flow capacity requested.
5) Blue indicates lowest cost option, green indicates second lowest cost option and orange indicates third lowest cost option.

FINAL October 25, 2017

Overview: The Three Bays Massachusetts Estuaries Project (MEP) Nitrogen Threshold Report indicated that the Marstons Mills River is one of the main collection points for freshwater and nitrogen (N) discharging to the headwaters of the Three Bays estuary.

The Three Bays estuary is presently impaired by nitrogen enrichment from nitrogen sources within its watershed. Restoration of impaired estuarine habitats will require a reduction in the nitrogen load from the watershed to meet the Mass DEP/USEPA Total Maximum Daily Load (TMDL) restoration threshold for the estuary. The example scenario included in the Three Bays MEP report indicated that to meet the N threshold for restoration, a 49% reduction in the load entering from the Marstons Mills River must be achieved. In surface water systems like the Marstons Mill River, a terminal fresh water pond generally removes about 50% of the entering nitrogen load prior to discharge to the down-gradient estuary.

MEP field measurements showed that Mill Pond is only removing about 22%-27% of the nitrogen passing through it. Analysis of Mill Pond itself indicates that this man-made pond has been filled with river-transported sediments over the past four centuries, and that re-establishment of the historic basin

depths is needed to restore pond function and a more typical level of nitrogen retention.

At present the retention time of water in Mill Pond is more than an order of magnitude lower than historically and lower than most ponds in the region. The very low retention time lowers the pond's nitrogen removal rate. Deepening the pond will enhance nitrogen removal likely from 25% to 35% up to 50% depending on the new basin depth and shape. This potential for a significant increase in nitrogen removal can be used by the Town of Barnstable to offset the need for wastewater infrastructure (sewers,) provided that the increase in nitrogen retention can be quantified and scientifically justified to Mass DEP.

The potential savings in restoration costs to the Town of deepening the pond is conservatively estimated to be in excess of $10 million. Critical to understanding the potential for enhanced natural attenuation in Mill Pond is quantifying the role sediments play in the uptake or release of nutrients to and from the water column, as this is where nitrogen removal occurs.

The main objective of the present biogeochemical investigation of Mill Pond sediments was to: a) conduct sediment sampling to quantify nitrogen recycling in the pond for comparison to earlier SMAST data, b) assess changes in sediment nitrogen dynamics, c) strengthen the baseline assessment prior to any deepening of the pond and d) provide a systems context for evaluating nitrogen removal by this fresh basin. The 2016 benthic nutrient regeneration effort was conducted using the same protocols and procedures used in the previous 2007 study, and in the MEP watershed loading and stream analysis.

Using the same approaches strengthens the reliability of comparisons and assessment of the degree to which nutrient flux rates may have changed over the past eight years. Reliable nutrient flux rates will then be available in the future should it be decided that a complete nutrient budget for the pond is needed to fully assess potential enhancement of nitrogen attenuation. In addition to the nutrient flux analysis, CSP/SMAST scientists also decided to bring together disparate datasets on nitrogen inputs and pond nitrogen flow-through to provide better context for restoration planning.

Measurements of Benthic Nutrient Regeneration, Sediment Oxygen Uptake and Denitrification

In order to determine the contribution of sediment regeneration to nutrient levels within Mill Pond and the potential nitrogen attenuation of watershed inputs to the headwaters of the Three Bays estuary, sediment samples were collected and incubated under *in situ* conditions during the period of maximum regeneration rates (summer interval, July-September). Time series measurements of total dissolved nitrogen, nitrate+nitrite, ammonium and ortho-phosphate, were made on each incubated core sample. The rate of oxygen uptake was also determined in order to evaluate sensitivity to oxygen depletion and general rates of organic matter decomposition. In 2008, assays were performed on two cores each for two sites (Cores 1 and 2; Cores 3 and 4, Figure 1). In 2016, cores were taken from the same two sites in duplicate, as in 2008, and a single core was taken from each of four additional sites to yield a more comprehensive overall pond-wide regeneration rate supportive of biogeochemical modeling.

In 2008, scientists from the Coastal Systems Program collected sediment samples from Mill Pond as part of the long-term water quality partnership with Three Bays Preservation, now known as Barnstable Clean Water Coalition. The focus of the effort was to determine sediment nutrient regeneration rates to assist potential restoration planning. While water samples associated with the flux study were collected and analyzed, the analytical data was not processed and synthesized into useful information on sediment nutrient regeneration rates.

Those data are presented herein along with data from the current project for comparison. Comparison of these two datasets will clarify the degree to which sediment biogeochemical conditions have changed or stayed the same in the pond and the potential effects on pond nitrogen attenuation. All assays were performed according to the same MEP protocols, with the exception of denitrification measurements which were not undertaken as part of the MEP.

2016 denitrification rates were determined by the state-of-the-art method of measuring excess N_2. N_2 excess was measured using membrane-inlet mass spectrometry (MIMS). N_2 produced by denitrification is precisely detected by analysis of its ratio with the inert gas Argon. Water samples were collected and stored to prevent gas exchange or bubble formation. In the laboratory, sample water was pumped at milliliter per minute rates through a gas permeable membrane to extract gas into the mass spectrometer inlet. The inlet is fitted with cryogenic traps to remove water vapor and CO_2 gas. Sample gas was analyzed by the mass spectrometer for molecular masses 28 and 40 for determining the N_2 to Ar ratio. Calibration was made by comparison with a reference gas of known composition. A quadrupole mass spectrometer (*e.g.*, Pfeiffer 422) was used for its sensitivity and speed of analysis.

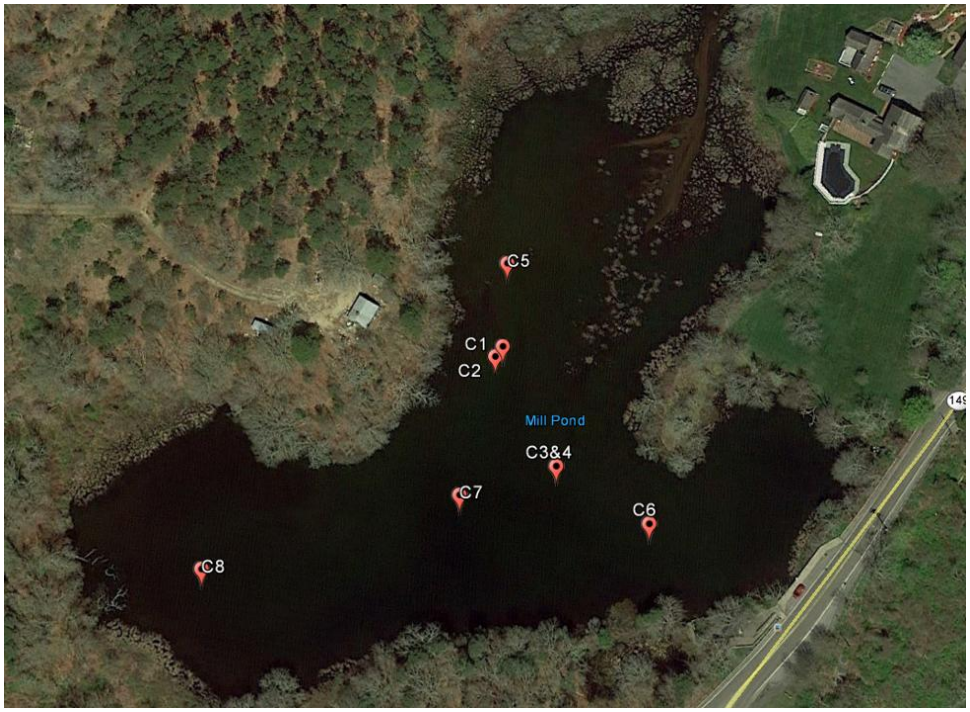

Figure 1. Map of Mill Pond showing locations of cores collected in 2008 (1,2,3,4) and 2016 (5,6,7,8) and the four additional sites sampled in 2016.

Results and Discussion

Input/Output Analysis: Building on the MEP analysis, it is possible to model the degree of nitrogen removal expected within Mill Pond. The MEP determined that the loading from the watershed based on land-use modeling was 11,657 kg/yr of nitrogen entering the watershed. Based upon modeled attenuation during transport of this input load, it was estimated that 6,984 kg/yr would reach Mill Pond via the Marstons Mills River. Measured flow and N load at the River discharge point to Mill Pond yielded

slightly more nitrogen removal in transport to the gauge than the model. However, both estimates show the importance of nitrogen removal within the upper watershed by natural wetlands, ponds and bogs consistent with the goal of increasing nitrogen removal in altered freshwater systems. At Mill Pond, the attenuation rate based on measured nitrogen load from the Marstons Mills River (measured over a hydrologic year) and from groundwater inflows directly to the pond from its watershed, yielded an estimate of nitrogen removal of 27%, much less than the average for freshwater ponds of >50%. The MEP Mill Pond attenuation rate is based upon measured Marstons Mill River nitrogen input load (4,690 kg/yr) and the direct watershed loading through groundwater (2,880 kg/yr) to Mill Pond which is unattenuated during transport. The measured outflow from Mill Pond (5,491 kg/yr) was used to determine pond-only attenuation.

Table 1. Modeled and measured nitrogen (N) loads that contribute to loads at the Marstons Mills River gauge above Mill Pond, groundwater loads to the pond from its watershed and nitrogen discharge from Mill Pond to the head of the Three Bays Estuary.

Modeled and Measured N Loads (MEP)	UnAtten N Load kg/yr	Atten %	Atten N Load kg/yr
All upper watershed flow to MMR gauge Modeled	11,657	40.1%	6,984
All upper watershed flow to MMR gauge **Measured**	--	59.8%	4,690
GW inflow to Mill Pond Modeled	2,880		2,880
GW to Pond + Stream Input **Modeled- Measured**	--		7,570
Stream outfow Mill Pond Modeled	--		6,369
Stream Output **Measured**	--	27%	5,491

SMAST Scientists working with Three Bays Preservation (now Barnstable Clean Water Coalition) staff conducted subsequent surface water flow studies to assess nitrogen removal by Mill Pond throughout the summer (critical management period.) These studies were conducted June through August 2007 and 2016, with nine evenly spaced sampling events during each summer. The concept was to evaluate seasonal attenuation of nitrogen during the period when the Three Bays estuary is most sensitive to nitrogen inputs. During these studies, flow and nitrogen load was determined at the Marstons Mills River discharge to Mill Pond (gauge site,) and at each of the two outflows from Mill Pond to the lower Marstons Mills River, which then discharges to the headwaters of the Three Bays estuary between Prince Cove and Warrens Cove. As measurements were only performed in summer, an annual attenuation cannot be determined from these measurements.

Summer 2016 was a low rainfall period with reduced recharge as seen in the lower river inflows and outflows. However, in both 2007 and 2016 the inflows to the pond were equal to the outflows within measurement error (4%). It appears that in both years, nitrate is significantly transformed to organic forms and likely denitrified within the anoxic surficial sediments, 25% and 35% nitrate-N attenuation in 2007 and 2016, respectively. However, total nitrogen removal in both years was low, only 2.1 kg/d loss within the pond, which translated to 7%-11% TN reduction (total nitrogen removal). The lower N retention is likely the result of a seasonal shift in nitrogen cycling as the sediments tend to release proportionately more nitrogen in warmer months, and retain remineralized nitrogen in the spring and fall. Given this likely seasonality, the lower values fit well with the annual attenuation derived from year-round measurements above (~25%).

Table 2. Input/Output analysis 2007 and 2016. Inputs from River and groundwater, outputsvia stream outflows			
2007 Summer			
	Flow (m3/d)	**NOx (kg/d)**	**TN (kg/d)**

Outflow-Inflow	**(481)**	**-5.1**	**-2.1**

Both nitrogen removal studies indicate rates of TN removal well below those typical of Cape Cod freshwater ponds, and indicate that restoration of Mill Pond will likely result in higher nitrogen capture. The low N removal rate is consistent with the residence time of water within Mill Pond. A simple analysis of residence time based upon the pond volume and average freshwater inflows yields a residence time of only about one day, compared to weeks to months for other similar acreage local fresh ponds.

Sediment Nitrogen Exchange Analysis: The sediment-water column nitrogen exchange rates measured in 2007 and 2016 are summarized in Table 3 and 4, respectively. The largest difference observed between the two years was in the rate of dissolved oxygen uptake. On cores collected in 2007 versus 2016 (cores 1, 2 and cores 3, 4) sediment oxygen demand (SOD) decreased 60%. Rates measured at the other four locations in 2016 cannot be directly compared as no prior data exists, however, the average rate is about 40% less than rates measured at the locations in 2007. Only a fraction of this difference can be explained by the difference in temperature between the years.

There is a simple explanation for this drop in oxygen demand. In the absence of any pond engineering or remediation work in the intervening years, the further shallowing of Mill Pond would result in less organic deposition to the sediments. Moreover, the lower flow conditions in the Marstons Mills River in 2016 would also result in less particulate organic matter inputs to the pond sediments. This lower particulate organic matter loading from the River was also seen in the 27% lower particulate carbon input in the summer stream analysis of 2007 and 2016, 14.8 kg/d and 11.7 kg/d, respectively. Adding to this is the secondary effect of lower organic carbon inputs from the River, and decreased in-pond production, resulting in a smaller pool of reduced compounds present within the sediment, which lowers oxygen demand. In other words, SOD rates in 2016 may have had a smaller oxygen uptake to support organic matter remineralization, and a smaller chemical oxygen demand combining for a lower measured SOD. The decreased deposition hypothesized for the observed change in SOD is supported by the observed parallel reduction in measured ammonium flux. Nitrate uptake, however, was nearly identical between

the two years as also seen in the inflow/outflow study (Table 2).

Denitrification rates were not made prior to those in 2016. Denitrification was relatively low with an average rate of 22 mg $N_2/m^2/d$ (0.78 mMol $N_2/m^2/d$). This value represents only 9% of the nitrogen cycling within the sediments and about 0.52 kg N/d.[1] This represents about 25% of the TN removal in the summer measurements; the remainder is almost certainly uptake by benthic algae, which should support coupled nitrification-denitrification after decay.[2] Enhancement of denitrification within Mill Pond should be possible in light of higher measured dentrification rates measured in other Cape Cod Ponds, the high nitrate concentrations remaining after passage through the pond. Enhancing nitrogen removal will depend on increasing the residence time for nitrate to be removed and the depth for settling of organic carbon and nitrogen particles.

Dredging the pond to increase the residence time of watershed inputs within the pond should result in greater attenuation of N loading to the Three Bays headwaters. However, this action alone may not be sufficient to meet the TMDL target load. Given the shallow depth of the water column, careful design consideration should be given to ensuring that restoration does not result in enhanced sediment resuspension and particulate N transport downgradient.

Conclusions

Synthesis of 2007 and 2016 nitrogen loading studies of Mill Pond supports some clear conclusions:

1. Mill Pond has been significantly altered by sediment inputs gradually filling it over the past four centuries, resulting in a very short water residence time (~1 day), which almost certainly results in a major reduction in the retention of nitrogen entering from the Marstons Mills River and the Pond's groundwater contributing area.

2. Removal of watershed derived total nitrogen by Mill Pond appears to be ~25% annually, but only 7%-11% in the June – August period, with mass removal being similar in the 2007 and 2016 summer stream studies (2.1 kg/d).

3. Nitrate entering Mill Pond is either removed (likely through denitrification) or transformed to organic nitrogen forms (25% - 35%), although most is discharged to the downgradient estuary. The high level of nitrate discharged from Mill Pond (0.5 mg/L even in summer) indicates there is strong potential for additional nitrogen removal within this basin.

4. Denitrification removes about 25% of the total nitrogen removed by Mill Pond in summer, a much lower fraction than other Cape Cod fresh ponds.

5. Enhancement of denitrification within Mill Pond should be possible in light of higher denitrification rates measured in other Cape Cod Ponds, the high nitrate remaining after passage through the pond and the low residence time.

Fertilizer Nitrogen and Phosphorous Control Ordinance (Barnstable Town Code Chapter 78)

Chapter 78

FERTILIZER NITROGEN AND PHOSPHOROUS CONTROL

GENERAL REFERENCES

Hazardous materials — See Ch. 108.

Toxic and hazardous materials — See Ch. 381.

Trees — See Ch. 221.

Wells — See Ch. 397.

Wetlands protection — See Ch. 237.

Wetlands buffer zone activity — See Ch. 704.

Herbicides — See Ch. 332.

§ 78-1. Purposes and intent.

A. Excessive nutrient enrichment of the region's groundwaters and surface waters may have significant public health ramifications, including direct detrimental effects on drinking water sources by increased concentrations of nitrates that can violate safe drinking water standards, and have negative impacts on economic, environmental and recreational resources and values in the Town and region.

B. The Town has significant glacially deposited sandy soils that are subject to rapid water infiltration, percolation, and leaching of nutrients.

C. This chapter incorporates by reference the University of Massachusetts Extension's Turf Management Best Management Practices. These practices, if followed, are deemed to protect the public health, safety and welfare and aid in achieving compliance with the total maximum daily loads (TMDL) for the Town's water resources prescribed by the Commonwealth of Massachusetts while allowing reasonable use of fertilizers for the enhancement and maintenance of turf quality.

§ 78-2. Applicability.

A. This chapter provides for a reduction of nitrogen and phosphorus entering the Town's waters and wetlands by means of an organized system of education, certification, standardization and regulation of practice. This chapter is not intended to eliminate the use of fertilizer.

B. This chapter adopts the best management practices as the normal operating procedures for turf management but not plants other than turf.

§ 78-3. Statutory authority.

This chapter is adopted as implementing regulations pursuant to and as authorized by the Fertilizer Management District of Critical Planning

Concern designation, Barnstable County Ordinance 13-07, and by Section 9 of Chapter 262 of the Acts of 2012.

§ 78-4. Definitions.

For the purposes of this chapter, the following words shall have the following meanings unless the context clearly indicates a different meaning:

AGRICULTURE/AGRICULTURAL USE — Farming in all of its branches, including the cultivation and tillage of the soil, the production, cultivation, growing, and harvesting of any agricultural, floricultural or horticultural commodities, including but not limited to cranberries.

BARNSTABLE — The Town and all of its waters.

BEST MANAGEMENT PRACTICES (BMP) — A sequence of activities designed to limit a nonpoint pollution source. For the purposes of this chapter and pursuant to § 78-5A of this chapter, "BMP" means the edition of Best Management Practices for Soil and Nutrient Management in Turf Systems, prepared by the University of Massachusetts Extension, Center for Agriculture, Turf Program in effect on September 18, 2014.

CERTIFIED FERTILIZER APPLICATOR — An applicator certified in the manner prescribed hereunder to apply fertilizer and manage turf in conformance with the BMP.

COMBINATION PRODUCTS — Sometimes known as "weed and feed," means any product that, in combination with fertilizer, contains pre- or post-emergence herbicides, insecticides, other pesticides or plant growth regulators.

COMPOST — The biologically stable humus-like material derived from composting, or the aerobic, thermophilic decomposition of organic matter, which is used as a fertility source for turf.

FERTILIZER — A substance that enriches turf with elements essential for plant growth, such as nitrogen, phosphorus, or other substances; fertilizer hereunder does not include dolomite, limestone, or lime, grass clippings, or compost/compost tea. "Fertilize, fertilizing, or fertilization" means the act of applying fertilizer to turf.

FERTILIZER APPLICATOR — Any person who applies fertilizer to turf and soils.

IMPERVIOUS SURFACE — A surface that has been compacted or covered with a layer of material so that it is highly resistant to infiltration by water, except for compacted areas on athletic fields, such as clay or baseball infields, intensely trafficked turf and the like.

LANDSCAPE PROFESSIONAL — A person, either as a sole proprietor or as part of a company, who, in exchange for money, goods, services, or other consideration, performs landscaping services. A landscape professional can include turf management staff at a private golf course operation or other private entity.

LANDSCAPING — For purposes of this chapter, establishment (including by sod, seeding, or transplanting), renovation, maintenance, management or fertilization of turf.

MUNICIPAL APPLICATOR — A public employee of a city, town, the county, or the state or federal government (or an employee of a department of and within such public entity) who fertilizes and manages turf located on property owned or controlled by a town, the county, the state or federal government (including publicly owned golf courses and athletic fields) within the scope of their official public employment responsibilities.

NONCERTIFIED FERTILIZER APPLICATOR — An applicator who is not certified in the manner prescribed hereunder to manage turf and apply fertilizer in conformance with the BMP.

NUTRIENT — Any of the following 17 elements needed for growth of a plant: the three nonmineral elements: carbon, hydrogen, and oxygen; the six macronutrients: nitrogen, phosphorus, potassium, calcium, magnesium, and sulfur; and the eight micronutrients: boron, copper, iron, chloride, manganese, molybdenum, nickel and zinc.

NUTRIENT MANAGEMENT — The systematic control of the application and availability of nutrients to plants in order to minimize nutrient loss and to maintain the productivity of the soil.

READILY AVAILABLE NITROGEN — Any water-soluble nitrogen (WSN) that is readily available to turf after application.

SLOW-RELEASE, CONTROLLED-RELEASE, TIMED-RELEASE, or SLOWLY SOLUBLE/AVAILABLE NITROGEN — Nitrogen in a form that delays its availability for uptake and use after application, and is not rapidly available to turf.

SOIL — The uppermost layer of the earth's surface, comprised of mineral and organic matter, which can host biological communities.

SOIL TEST — A technical analysis of soil conducted by a soil testing laboratory that uses standards recommended by and in agreement with the University of Massachusetts Amherst Extension Program BMP, including a Modified Morgan soil testing procedure and extractable nutrient values.

TURF — Grass-covered soil held together by the roots of the grass, also known as "sod" or "lawn."

WATERS or WATER/BODIES — Includes, but are not limited to, streams, including intermittent streams, creeks, rivers, freshwater and tidal wetlands, ponds, lakes, marine waters, canals, lagoons, and estuaries within the Town, including without limitation all waters defined in Massachusetts General Laws, Chapter 131, Section 40, and the Town Wetland Ordinance or Regulations, with the exception of the following: coastal and inland banks, beaches, coastal dunes, dune fields, and lands subject to coastal storm flowage, inland or coastal flooding or inundation, or within 100 feet of the hundred-year storm line.

§ 78-5. Standards of performance.

A. Best management practices. The best management practices (BMP), as defined herein, shall be applied to the standards of performance.

B. Performance standards for noncertified fertilizer applicators. Fertilizer applicators who do not hold fertilizer certification issued in accordance with § 78-6B of this chapter shall comply with the following standards for fertilizer applications to turf:

(1) Noncertified fertilizer applicators shall not apply fertilizer during or immediately prior to heavy rainfall, such as but not limited to thunderstorms, hurricanes, or northeastern storms, or when the soil is saturated due to intense or extended rainfall;

(2) Noncertified fertilizer applicators shall not apply fertilizer or compost between November 12 and the following March 31;

(3) Noncertified fertilizer applicators shall not apply, spill, or deposit fertilizer on any impervious surface and fail to remove the applied, spilled, or deposited fertilizer immediately (and in which case the applicator shall then either contain, dispose of legally or apply the fertilizer as allowed), and shall not apply, spill or deposit fertilizer in a manner that allows fertilizer to enter into storm drains;

(4) Unless the Town's existing laws and regulations, including its Wetland Ordinance or Regulations, contain a stricter standard or other enforcement or approval mechanism such as through the Town's Conservation Commission, which shall control, noncertified fertilizer applicators shall not apply fertilizer closer than 100 feet to any water body, or within the Zone I of a public drinking water well unless permission is obtained through the enforcement authority set out in § 78-6D(1) herein allowing such activity;

(5) A noncertified fertilizer applicator shall not apply fertilizer that contains phosphorus, unless a soil test taken not more than three years before the proposed fertilizer application indicates that additional phosphorus is needed for growth of that turf, or unless establishing new turf or reestablishing or repairing turf after substantial damage or land disturbance, in which case the application shall be in compliance with the BMP;

(6) A single application of fertilizer that contains nitrogen shall not exceed 1.0 pounds of actual nitrogen per thousand square feet, shall consist of at least 20% slow-release nitrogen fertilizer (NOTE: This represents the minimum percentage: use of higher SRN content is generally preferable, especially on sandy root zones, during stress and pre-stress periods, and when there are fewer annual applications of nitrogen made to a lawn.) and the annual rate shall not exceed 3.2 pounds of actual nitrogen per thousand square feet. Single applications shall be done at intervals of no less than four weeks until the annual maximum is reached;

(7) The fertilizer application requirements of this § 78-5B shall apply with the same limitations to combination products, i.e., amount of nitrogen applied, vicinity of water bodies, etc;

(8) Noncertified fertilizer applicators shall not deposit grass clippings, leaves, or any other vegetative debris into or within 50 feet of water bodies, retention and detention areas, drainage ditches or stormwater drains, or onto impervious surfaces, such as, but not limited to, roadways and sidewalks, except during scheduled clean-up programs.

C. Performance standards for certified fertilizer applicators. Certified fertilizer applicators shall be exempt from the requirements set forth in § 78-5B of this chapter, provided that they shall manage turf and apply fertilizer to turf in accordance with the BMP. The burden shall be on the certified fertilizer applicator, if and as required, to show that he/she is applying fertilizer in accordance with the BMP.

D. Exemptions. The following activities shall be exempt from this chapter:

(1) Application of fertilizer as a fertility source for agriculture and agricultural use.

(2) Application of fertilizer as a fertility source to home gardens, landscape ornamentals, shrubs, trees bushes, vegetables, fruit and container plants.

§ 78-6. Education; certification; enforcement; penalties.

A. Fertilizer/turf management education. Fertilizer education may consist of, but is not limited to, collaboration with retailers to post in-store information on Town fertilizer regulations, the BMP and fertilizer certification requirements; mailings and flyers for the general public concerning Town fertilizer regulations, the BMP and fertilizer certification requirements; and outreach to landscape professionals and municipal applicators concerning fertilizer-related laws, the BMP and fertilizer certification requirements. The Town may rely on Cape Cod Cooperative Extension to assist in maintaining a program of fertilizer and turf management education that is based on the BMP.

B. Fertilizer certification.

(1) The Town may seek the assistance of the Cape Cod Cooperative Extension to establish application requirements for and the process required to obtain fertilizer certification and renewals thereof, including evidence that the applicant is proficient in the BMP. Any noncertified fertilizer applicator may then apply to the Town or Cape Cod Cooperative Extension, as the case may be, for fertilizer certification as a certified fertilizer applicator.

(2) Notwithstanding the requirement for a proficiency assessment set out in § 78-6B(1) above, municipal applicators or landscape

professionals who meet the following criteria shall be presumed to be proficient in the BMP and may become certified fertilizer applicators without the need for an additional proficiency assessment or fees:

(a) Current Massachusetts pesticide commercial applicator license (Category 00) or commercial applicator license with turf certification (Category 37) or commercial applicator license with shade tree and ornamentals certification (Category 36), with evidence of participation in a recognized continuing education program for turf management within the past year; or

(b) Active membership in the Cape Cod Landscapers Association, the Golf Course Superintendents Association of Cape Cod, Massachusetts Association of Lawn Care Professionals (MALCP) or a substantially similar organization and any one of the following:

[1] Associate's Degree or higher in turf management, or closely related field, with evidence of participation in a recognized continuing education program for turf management within the past year;

[2] Current Massachusetts Certified Landscape Professional (MCLP) certification or current Massachusetts Certified Arborist (MCA) certification, or substantially similar professional certification with emphasis on turf management, with evidence of participation in a recognized continuing education program for turf management within the past year;

[3] Certificate of Completion from the University of Massachusetts Extension Green School (Turf or Landscape sections) or the University of Massachusetts Winter School for Turf Managers, or a horticultural certificate from Cape Cod Community College, or substantially similar professional certification with emphasis on turf management, with evidence of participation in a recognized continuing education program for turf management within the past year.

(3) The Town may seek the assistance of the Cape Cod Cooperative Extension to help develop or administer an assessment to determine an applicator's proficiency in the BMP and to assist with or administer a fertilizer certification process, which if administered by the Extension, may be a county-wide process.

(4) Municipal applicators or landscape professionals who are noncertified fertilizer applicators may nonetheless apply fertilizer and manage turf pursuant to the standards for certified fertilizer applicators set out in § 78-5C of this chapter so long as they

fertilize and manage turf under the direct supervision of a manager or supervisor who has attained fertilizer certification hereunder. "Direct supervision" shall mean the instruction and control by such manager or supervisor who is responsible for fertilizer applications made and that person making them, and who is either physically present at the time and place the fertilizer is applied, or if not physically present, is available if and when needed.

(5) All certified fertilizer applicators shall ensure that a copy of the official documentation of said fertilizer certification is readily available when and at the location fertilizer is being applied, and shall provide such certification when requested to do so by an officer or agent of the enforcement authority set out in § 78-6D(1) herein.

(6) All certified fertilizer applicators who apply plant nutrients shall maintain records for three years of each application made. The following information shall be recorded, when applicable:

(a) Name of applicator;

(b) Date of application;

(c) Address or location description of the application site;

(d) Type and amount of nutrients applied;

(e) Size of the area being treated;

(f) Representative nutrient value or values (e.g., soil tests);

(g) Plant nutrient analysis of product used;

(h) Method and rate of application;

(i) Total amount used;

(j) An original or legible copy of the label of the plant nutrient; and

(k) The implementation of all activities or protocols recommended or required by the nutrient management plan, if applicable.

(7) The records required under this § 78-6B shall be made available for inspection by the Town's Director of Public Health.

C. Retailer requirements. Any retailer who sells, or offers for sale, phosphorus-containing fertilizer shall:

(1) Display the product separately from nonphosphorus plant nutrients;

(2) Post in a location where phosphorus-containing fertilizer is displayed a clearly visible sign, provided by the Town, at least 8 1/2 inches by 11 inches in dimension, which reads as follows:

"PHOSPHORUS RUNOFF POSES A THREAT TO WATER QUALITY. THEREFORE, UNDER GL Ch. 128 sec. 65A, PHOSPHORUS CONTAINING FERTILIZER MAY ONLY BE APPLIED TO LAWN OR NON-AGRICULTURAL TURF WHEN (i) a soil test indicates that additional phosphorus is needed for the growth of that lawn or non-agricultural turf; or (ii) it is used for newly established lawn or non-agricultural turf during the first growing season."

(3) Post education materials on proper soil testing and use of fertilizers in a prominent location where fertilizer is being sold.

D. Enforcement.

(1) Enforcement authority. This chapter shall be enforced by the Town's Board of Health, through its Director of Public Health; provided, however, that the Town's Conservation Commission shall enforce the provisions of § 78-5B(4) and (8).

(2) For first and second offense within a twelve-month period. After the first year from the effective date of this chapter, whoever violates any provision of this chapter by committing a first or second offense may be penalized as follows:

(a) First offense: a written warning shall be issued;

(b) Second offense within a twelve-month period: either by attending an education program under § 78-6A or by obtaining a certification under § 78-6B.

(3) Noncriminal disposition. After the first year from the effective date of this chapter, whoever violates any provision of this chapter three or more times in a twelve-month period may be penalized by a noncriminal disposition process as provided in MGL c. 40, § 21D and the Town's noncriminal disposition ordinance. If noncriminal disposition is elected, then any person who violates any provision of this chapter shall be subject to a penalty of not more than $300 for each violation.

(4) Other remedies. The Town's Board of Health, through its Director of Public Health, or the Town's Conservation Commission for violations of § 78-5B(4) and (8) may enforce this chapter or enjoin violations thereof through any lawful process, and the election of one remedy by the Town's Director of Public Health and the Conservation Commission shall not preclude enforcement through any other lawful means.

§ 78-7. Severability.

Should any section, part or provision of this chapter be deemed invalid by a court of competent jurisdiction, such decision shall not affect the validity of the remaining terms of this chapter as a whole or any part thereof, other

than the section, part or provision held invalid, which shall remain in full force and effect.

§ 78-8. Amendments.

A. No amendment to this chapter shall be adopted until such time as the Town Council shall hold a public hearing thereon, notice of the time, place and subject matter of which, sufficient for identification, shall be given by publishing in a newspaper of general circulation in the Town once in each of two successive weeks, the first publication to be not less than 14 days prior to the date set for such hearing. No such amendment shall be effective unless the proposed amendment has been approved by the Town Council.

B. Amendments shall also be subject to the procedures set out in Sections 10 and 11 of the Cape Cod Commission Act, Chapter 716 of the Acts of 1989, as amended. Specifically, amendments must also be consistent with the Fertilizer Management District of Critical Planning Concern designation, Barnstable County Ordinance 13-07 and the Guidelines for Implementing Regulations set out therein, including the requirement for consistency with the BMP.

§ 78-9. When effective.

The effective date of this chapter shall be the date the fertilizer certification process outlined in § 78-6B herein is implemented and in effect.

Ed Eichner, Principal Water Scientist, TMDL Solutions
John Ramsey, Principal Coastal Engineer, Applied Coastal Research and Engineering

Date: December 5, 2019

RE: MEP Scenarios: Town of Barnstable Wastewater Plan and Land Use Updates

I. Background

The Town of Barnstable in working to implement a Wastewater Plan that includes reducing excessive nitrogen loads to its coastal estuary waters. Among the key estuaries with watersheds within the Town boundaries are: Lewis Bay/Halls Creek, Centerville River, Three Bays, and Barnstable Great Marshes. Portions of each of these estuaries are impaired by excessive watershed nitrogen loads and all of the watersheds, except Centerville River, include adjacent towns. However, it is Barnstable's land use nitrogen sources, primarily wastewater, that are the primary determinants of the water quality characteristics within each of these estuaries.

Between 2001 and 2017, the Massachusetts Estuaries Project (MEP) completed assessments of estuaries throughout southeastern Massachusetts. These assessments determined whether the habitat and water quality within these estuaries was impaired and developed linked watershed/water quality models that could be used to reliably test potential nitrogen management strategies to restore acceptable water quality. The technical lead for these MEP assessments was the Coastal Systems Program from the School for Marine Science and Technology at UMass-Dartmouth (CSP/SMAST). MEP reports for Three Bays, Centerville River, Lewis Bay/Halls Creek, and Barnstable Great Marshes were completed in 2006[1], 2006[2], 2008[3], and 2017[4], respectively.

Massachusetts Estuaries Project Linked Watershed-Embayment Model to Determine the Critical Nitrogen Loading Threshold for the Barnstable Great Marshes - Bass Hole Estuarine System, Towns of Barnstable and Dennis, Massachusetts, Massachusetts Department of Environmental Protection. Boston, MA. 213 pp.

The federal Clean Water Act requires each impaired surface water to have a Total Maximum Daily Load (TMDL) developed for the contaminant causing its impairment. The Massachusetts Department of Environmental Protection (MassDEP) is using the MEP assessments as the technical basis to develop total nitrogen TMDLs for each impaired estuary or segments within these estuaries. These TMDLs must be jointly approved with the US Environmental Protection Agency (EPA) and, to date, EPA and MassDEP have approved nitrogen TMDLs for 21 estuarine systems (41 TMDL segments) in southeastern Massachusetts utilizing the associated MEP assessments. Final total nitrogen TMDLs have been approved for Three Bays[5], Centerville River[6], and Lewis Bay[7]; Barnstable Great Marshes does not currently have a nitrogen TMDL though a portion was identified through its MEP assessment as being impaired.

As mentioned, each MEP assessment included development of linked nitrogen watershed/water quality models and contemporaneous estuary-specific ecosystem measures. Each of the MEP models was calibrated and verified with independent datasets so that they could be used to accurately predict future water quality conditions throughout each system. These models have been used throughout southeastern Massachusetts in a variety of settings, including assessment of wastewater management plans. Each estuary-specific model provides a reliable tool for watershed communities to assess the impacts of potential nitrogen management actions.

The Town of Barnstable has proposed a 60-year, three-phased wastewater plan that uses and builds on the existing wastewater infrastructure, including the municipal Hyannis Water Pollution Control Facility (WPCF).[8] This proposed plan is flexible depending on future changes, but one of the key features is additional sewer connections to the WPCF. With this in mind, Town staff asked CSP/SMAST to use the MEP models for Lewis Bay/Halls Creek, Centerville River, Three Bays, and Barnstable Great Marshes to evaluate two scenarios for each estuary: 1) updated current watershed nitrogen loads based on current land use conditions and 2) reduced watershed nitrogen loads based upon the Town's Wastewater Plan after the plan is completely implemented. These scenarios were constructed so that only watershed nitrogen loads were changed in the MEP models; no changes were made to the bathymetry or tidal functions within the MEP models. Each of these scenarios required development and integration of updated data, including incorporation of changes in the wastewater plan as it evolved during the course of the project. The present Technical Memorandum builds on the watershed updated nitrogen loading Technical Memorandum of October 9, 2019[9], which indicated a high probability that the Wastewater Plan as proposed would meet the nitrogen loading reductions required to restore Barnstable's estuaries. The present Technical Memorandum combines the watershed nitrogen loading changes with each

estuaries nitrogen dynamics and hydrodynamics to yield the most accurate assessment of the effectiveness of the proposed Wastewater Plan.

II. Scenario Inputs: Updated Land Use Data and Wastewater Plan Sewering

In order to develop the updated land use and wastewater plan scenarios, project staff worked with Town DPW and GIS staff, as well as staff from the public water suppliers to obtain updated information for use in the MEP watershed models, including current parcels, assessor's land uses, water supplier water use accounts, current and planned connections to the sewer system, and road layouts. Project staff reviewed and cross-checked this data for consistency and other quality assurance/quality control issues. Each of the categories of updated information is discussed below.

II.1. Land Use and Water Use

Because the MEP assessments of Lewis Bay/Halls Creek, Centerville River, Three Bays, and Barnstable Great Marshes were completed in different years, the impact of changes in the land use and water use information obtained from the Town for each assessment were different. In addition, project staff needed to assess whether the provided data was reasonably consistent (*e.g.*, water use pumped by water suppliers balanced water billed within supplier service areas). These types of checks were also completed during the MEP to ensure that data was representative and, therefore, reliable for evaluating impacts of nitrogen management strategies.

In the MEP assessments, water use was used as a proxy for wastewater generation along with correction factors for consumptive use, such as lawn irrigation. Consumptive use will vary, however, based on a number of factors, including how frequently precipitation occurs, whether precipitation is clustered on a few days or spread over many days, and how long and when high temperatures occur during the summer/plant growing season. MEP assessments generally used average water use over a period of years in order to smooth out exceptionally high or low consumptive use years.

For the current project, project staff worked with Town staff to collect annual water pumping rates between 2002 and 2018 for all of the public water suppliers within the Town: Centerville Osterville Marstons Mills (COMM) Water Department, Barnstable Fire District (BFD), Town of Barnstable Water Supply Division (Hyannis), Cotuit Fire District Water Department (Cotuit). Data review included looking at annual pumping rates, rates per service connection, and annual averages over various timeframes. Review of individual annual pumping rates among the Barnstable public water suppliers showed high year-to-year variation (5 to 20%) from the average rates between 2002 and 2018 (**Figure 1**). Rolling averages of 3 to 5 years of pumping generally showed results close to the average between 2002 and 2007, a period of below average, declining pumping between 2008 and 2014, and then a period of above average pumping between 2015 and 2018. After additional discussion, Town and project staff decided that averaging water use between 2011 and 2016 would be appropriate. More restricted timeframes also approximated average conditions, but the 2011 to 2016 averages were reasonably recent, had been used in previous Wastewater Plan discussions, and were already linked to the town parcel dataset. Water supply well pumping during this period was slightly (<5%) above average, but it was thought in Town and project staff discussions that this small degree of conservatism would be a benefit in assessing the modeling projections.

Once 2011 to 2016 was determined to be an appropriate period for water use in the watershed nitrogen loading updates, project staff then compared total annual water use for all parcels within the respective service areas during this period with the well pumping rates for each of the individual public water suppliers. This quality control step was undertaken to ensure that the assigned water uses in the Town parcel database were in reasonable balance with the water pumped by the water suppliers and ensure that no significant water use/wastewater volumes were missed in the watershed nitrogen loading calculations. Usually water pumping rates are greater than water use due to standard maintenance of portions of the water supply system, such as blow-offs for hydrants and well pumps. The initial comparison for the Barnstable parcels found that pumping rates tended to be greater than parcel water use with annual pumping rates 3% to 22% higher than parcel water uses with variations from year to year and between suppliers. Project staff discussed these differences with the respective water superintendents and generally found estimated blowoff volumes resulted in narrowed differences between billed water use and pumping rates. The largest volume water supplier, COMM, had annual differences of only 3% to 6% between billed water use and well pumping rates. Cumulative town-wide differences between pumping rates and cumulative parcel water use varied between 7% and 9%. As a result of this analysis, the average 2011 to 2016 water use assigned to the parcels appears to be in reasonable balance with the pumping rates. As such, these average water uses were appropriate for use as a wastewater proxy for septic system flows in the update of the MEP watershed nitrogen loading models.

The next quality control step was to compare the effluent flows at the Hyannis Water Pollution Control Facility (WPCF) to the cumulative water use for parcels within the sewer collection area. Based on data provided by the Town, effluent flows and total nitrogen (TN) loads at the WPCF have increased between 2011 and 2018 (**Figure 2**). As such, comparing the cumulative water use within the service area to the effluent discharge from the WPCF needs to consider cumulative water use within the service areas and WPCF effluent flow within individual years.

Typically, it should be expected that water use should be greater than effluent discharge because of consumptive use of water (*e.g.*, irrigation water is delivered to a property, but is not discharged to the sewers). Although this is the usual relationship, there are factors that may modify this relationship, including groundwater or stormwater infiltration into the collection system and/or imperfect tally of sewer accounts (*e.g.*, unrecorded or illicit sewer connections). The initial comparison found that the total flow between 2011 and 2015 from parcels with sewer connections in the Town databases was less than the measured effluent flow at the WPCF. After identifying this issue, project and Town staff re-reviewed the GIS sewer assignments and water use in Hyannis, which is the predominant sewer service area, and found some mismatches in the two databases that suggest a more extensive review outside of the current project should be completed. After correction based on an initial sweep of the two databases, sewer service area water uses in 2011 and 2015 were greater than effluent flow at the WPCF, while 2012, 2013, and 2014 were still less than the measured effluent flow. While this is an on-going issue, the net cumulative difference across the five years is less than 1% and this is well within the estimated error in the past assessments of MEP water quality modeling results. After this QC review, the sewered properties GIS coverage was deemed reasonable for use in the scenarios.

In order to update the non-wastewater nitrogen loads in the MEP models, project staff also received updated Town databases of: a) building areas, b) road layouts, and c) areas of other impervious surfaces (*e.g.*, parking lots, patios, tennis courts, etc.). These databases were more refined than the

base data available at the time of the development of the MEP models, so they provided a more accurate representation of these areas and their associated nitrogen loads. Comparison of these areas to the Town parcels layouts found some overlaps of the buildings across parcel boundaries, especially in the Lewis Bay watershed; project staff corrected these as presented during the development of the watershed nitrogen loading models, but again this represents a GIS quality assurance task outside of the current project and something the Town should consider as a future task. Quality control checks comparing whole watershed building areas to cumulative subwatershed building areas were within 3%. In the current project, building, road, and other impervious surface areas within subwatersheds shared with adjacent towns were updated if they were within a watershed shared with Barnstable parcels, otherwise they retained the MEP building areas in the scenarios. No updates were made in the assumed fertilized lawn areas or turf areas at schools or golf courses. It should also be noted that the standardized state land use codes used by the Town Assessor and the MEP assessments generally changed from when the codes used in the original MEP assessments, especially for the Three Bays, Centerville River, and Lewis Bay assessments.

II.2. Wastewater Nitrogen Loads: Sewered Areas and Wastewater Flow, Denitrifying Septic Systems, and Small Wastewater Treatment Plants

The MEP assessments included available review of recorded effluent flows, nitrogen concentrations, and nitrogen loads for municipal wastewater treatment plants, private treatment plants and innovative/alternative denitrifying septic systems. This information was updated for current conditions scenarios and then adjusted based on the scenarios based on the Town's Wastewater Plan.

The Town has four wastewater treatment facilities within the study area (**Table 1**). Two of these are private and two are municipal, including the largest one: the Hyannis Water Pollution Control Facility (WPCF). The second municipal treatment facility is located in Marstons Mills and provides wastewater treatment for West Village Elementary School and Barnstable United Elementary School. The effluent from the smaller private facilities discharge to subwatersheds were the facilities are located, while the larger Hyannis WPCF discharge is spread over a number of subwatersheds because of the volume of treated effluent discharged and the associated groundwater mounding. The division of effluent flow among subwatersheds impacted by the Hyannis WPCF were determined as part of pre-208 groundwater modeling project between the US Geological Survey and the Cape Cod Commission.[10] This project used an adapted version of the regional USGS groundwater model of the Sagamore Lens to predict which surface waters and public water supply wells were impacted by effluent from existing and proposed municipal treatment facilities, including the Hyannis WPCF. Results from this USGS assessment were used in the Lewis Bay/Halls Creek MEP assessment and the apportionment is the same in the scenarios summarized in this memo. As mentioned above, properties currently connected to the municipal sewer systems were indicated in the Town-provided GIS parcel coverage, while properties connected to the private facilities were previously confirmed during the development of the MEP assessments (**Figure 3**).

For the completion of the current requested scenarios, Town staff provided recent treatment data for the two municipal facilities (*i.e.*, effluent flows and total nitrogen concentrations), while

[10] Walter, D.A. 2008. Use of Numerical Models to Simulate Transport of Sewage-Derived Nitrate in a Coastal Aquifer, Central and Western Cape Cod, Massachusetts: U.S. Geological Survey Scientific Investigations Report 2007-5259, 41 p.

MassDEP provided updated treatment data for the two private facilities: Cape Regency Nursing Home in the Centerville River watershed and Cotuit Landing in the Three Bays watershed.[11] Both of these private facilities have wastewater flows greater than the 10,000 gpd threshold required for Groundwater Discharge Permits from MassDEP and are required to regularly report monitoring of flow, nitrogen concentrations and other effluent characteristics. Under the Town's Management Plan scenario, the properties connected to these treatment facilities would be connected to the municipal sewer system.

In the 2019 Wastewater Plan scenarios for each of the four estuaries, future sewered properties were determined based on information provided by the Town. In addition to the properties that would be sewered under the Plan, Town staff also determined where collected wastewater would be treated and discharged. Wastewater collected for treatment at the WPCF included the current service area within the Lewis Bay, Barnstable Harbor, and Centerville River watersheds, the additional future sewered properties, and a service area within the Town of Yarmouth section of the Lewis Bay watershed (**Figure 4**). A collection system in the western portion of Town would also be developed, but this flow would be treated and discharged at an as-yet-undetermined wastewater treatment facility outside of the Town boundaries; wastewater in this area would be within both the Three Bays and Popponesset Bay watersheds. Wastewater to the east of this westernmost collection area would flow to the Hyannis WPCF.

The Plan also specifies where treated wastewater effluent will be discharged. Effluent discharge at the Hyannis WPCF site would be limited to 2 MGD (with a 3 mg/L TN concentration) under the Plan scenarios. Collected wastewater flow from the Yarmouth collection area would be treated at the Hyannis WPCF, returned to Yarmouth, and discharged outside of the Lewis Bay watershed. Remaining WPCF effluent greater than 2 MGD would be discharged at a location within the Barnstable Harbor watershed (see **Table 1)**. Total current wastewater effluent at the WPCF is 1.47 MGD, while treated wastewater at the WPCF will be 3.82 MGD under the Wastewater Plan.

In addition to updated performance data on the larger wastewater treatment facilities, project staff also obtained and incorporated monitoring performance data for innovative/alternative (IA) denitrifying septic systems from the Barnstable County Department of Health and Environment (BCDHE).[12] BCDHE maintains nitrogen monitoring results on IA septic systems and has results from 59 systems within the Town of Barnstable. Project staff determined average total nitrogen concentrations for each IA system that had data from three or more samplings and incorporated these results into the current conditions and Wastewater Plan scenarios for each associated property. If a property was selected for a sewer connection under the Wastewater Plan (including those with IA systems), no wastewater nitrogen load was assigned to that property under the Plan scenarios.

III. Scenario Results: Updated Current Conditions and Wastewater Plan Changes

Project scenarios were completed in pairs for each of the estuaries: a) one for a 2019 update of current land uses and associated watershed loading and b) another using the 2019 Wastewater Management Plan proposed sewer strategy coupled with the 2019 update of current land uses. Each scenario was run through the MEP Linked Watershed-Embayment Nitrogen Management Model for each estuary. Aside from the updated watershed nitrogen loads, the MEP water quality

[11] Brian Dudley and Christos Dimisioris, MassDEP, SERO (personal communications)

[12] Emily Michele Olmsted and Brian Baumgaertel, BCDHE (personal communications).

model, including the bathymetry and tidal movements developed during the MEP assessment, were not changed. For the purpose of comparing the results from the scenarios, only the watershed nitrogen loads were changed with the standard adjustment of the internal sediment nitrogen recycling related to changes in watershed load. Updated projections of future buildout within each watershed were also not included in the selected scenarios.

III.1. Three Bays Scenarios: Updated Current Conditions and Town Wastewater Plan Results

The final MEP assessment report on the Three Bays estuary system was completed in 2006. The Three Bays MEP watershed nitrogen loading model was based on digital parcels and land use data obtained from the watershed towns for the following years: 2004 for Barnstable, 2000 for Sandwich, and 2001 for Mashpee. Tidal data, bathymetry, and shoreline configuration for the Three Bays MEP water quality model were collected in 2002 and water quality data that was used was collected between 1999 and 2004. Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that portions of the system ranged in condition from severely degraded (Warrens Cove, Princes Cove, Upper North Bay) to moderately impaired (Cotuit Bay, West Bay).[13] The MEP team recommended target total nitrogen concentrations to address the impairments and used the linked MEP models to develop a potential watershed nitrogen reduction option to attain the target TN concentrations. In 2007, MassDEP/EPA approved a TMDL with nitrogen loading limits for six segments: Cotuit Bay, West Bay, North Bay, Prince Cove, Warren Cove, and Prince Cove Channel.[14]

The updated 2019 current watershed loading utilized the updated (current conditions) data inputs discussed above. Notable among these changes were: 1) more complete accounting of impervious surfaces (*e.g.*, road surfaces, building areas, parking lots), 2) changes in cranberry bog areas (*e.g.*, a number of bogs in the watershed became inactive in the past 15 years), 3) changes in land use (*e.g.*, change from undeveloped lots to singles family residences), 4) updated nitrogen loads from the capped Town landfill, and 5) increases in the number of properties connected to the public water supply systems (*e.g.,* the number of single family residences with public water supply accounts increased by 440 from the MEP count).

The updated current conditions increased the attenuated system nitrogen load by +8.2% over the MEP system load, while the system unattenuated load changed very little (+0.8%) compared to the MEP load (**Table 2**). Most of the changes were due to increased impervious surface loads, which were somewhat offset by decreased wastewater loads. The relatively higher increase in the attenuated loads was due to changes in the spatial distribution of the loads within the watershed with relatively greater loading increases in the lower portion of the watershed which does not attenuate watershed loads compared to the uppermost portion in the Prince Cove subwatershed.

The proposed 2019 Town Wastewater Plan scenario includes provisions to connect large portions of the Three Bays watershed to a municipal sewer system (see **Figure 4**). As mentioned above, the collected wastewater will be split with a portion transferred out of the watershed to an as-yet-undetermined site (*i.e.*, west sewered area) and the remaining portion would be transferred to the Hyannis WPCF (*i.e.*, east of the dividing line between the east and west areas). The nitrogen loads associated with the Town Wastewater Plan significantly decreased the watershed-wide attenuated

[13] See Table VIII-1 in Three Bays MEP Report (Howes and others, 2006).

[14] MassDEP. 2007. Three Bays System TMDLs for Total Nitrogen (Report # MA96-TMDL-10, Control # CN242.0).

updated load by -39% with the majority of the decrease occurring within the combined Prince Cove subwatershed.

The MEP used the watershed nitrogen loads with estimates of atmospheric nitrogen deposition on the estuary surface and measured nitrogen regeneration from the estuary sediments (*i.e.* benthic flux) as inputs to a linked watershed-water quality model that also used measurements of system hydrodynamics based upon bathymetry and tidal changes throughout the Three Bays system (**Table 3**). This model was calibrated and validated against water quality data collected at various monitoring stations in order to provide a predictive tool for future nitrogen management strategies. These results were compared to other measurements throughout the Three Bays system, including dissolved oxygen and habitat quality, to understand which portions of the system were impaired and what target threshold nitrogen concentrations should be goals to restore the water quality and habitat throughout the system. The MEP team selected a threshold water quality target of 0.38 mg/L total nitrogen (TN) for a sentinel station in the narrows between North Bay and Cotuit Bay. Estimates of nitrogen loads to attain this target was developed and incorporated in the MassDEP TMDL for Three Bays.[15]

Using the MEP Linked Watershed-Embayment Nitrogen Management Model, TN concentrations throughout the system were determined for the nitrogen loads from the 2019 updated land use and the loads associated with the Town's Wastewater Plan (**Table 4**). The increased nitrogen loads resulting from the 2019 updated land use resulted in increased TN concentrations throughout the system ranging from +1% at the North Bay (south) TB6 station to +25.6% at the West Bay (north) TB8 station. In contrast, the reduced nitrogen loads estimated from the proposed Wastewater Plan showed significant TN concentration reductions throughout the system generally in the -35% to -40% range. However, the TN concentration reduction at the sentinel station was insufficient to attain the 0.38 mg/L threshold concentration. This was expected as there are other nitrogen removal alternatives being planned for the upper watersheds to the Three Bays Estuary, particularly within the Marstons Mills River sub-watershed.

III.2. Centerville River Scenarios: Updated Current Conditions and Town Wastewater Plan Results

The final MEP assessment report on the Centerville River estuarine system was completed in 2006. The MEP watershed nitrogen loading model was based on digital parcels and land use data obtained from the Town of Barnstable in 2004; the Centerville River watershed is completely within the Town. Tidal data and bathymetry/shoreline configuration data for the Centerville River MEP Linked Watershed-Embayment Nitrogen Management Model were collected in 2004 and 2003, respectively. Water quality data that was used in the model was collected between 2001 and 2005 (five years). Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that portions of the system ranged in condition from significantly impaired (East Bay, Lower Centerville River) to healthy (Upper Centerville River, Bumps River).[16] The MEP team recommended site-specific target total nitrogen concentrations to address the nitrogen-related impairments and used the linked MEP models to develop a potential watershed nitrogen reduction option to attain the target TN concentrations. In 2007, MassDEP/EPA approved a TMDL with nitrogen loading limits for three segments: Centerville River, East Bay, and Scudder Bay.[17]

[15] MassDEP. 2007. Three Bays System TMDLs for Total Nitrogen (Report # MA96-TMDL-10, Control # CN242.0).

[16] See Table VIII-1 in Centerville River MEP Report (Howes and others, 2006).

[17] MassDEP. 2007. Centerville River-East Bay System TMDLs for Total Nitrogen (Report # 96-TMDL-14, Control # CN248.0).

The updated 2019 current watershed loading utilized the data inputs discussed above. Notable among these changes were: 1) more complete accounting of impervious surfaces (*e.g.*, road surfaces, building areas, parking lots), 2) changes in area of active cranberry bog (*e.g.*, a number of bogs in the watershed have been removed from cultivation (inactive) over the past 15 years), and 3) changes in land use (*e.g.*, increase of 396 single family residences).

The updated current conditions increased the attenuated nitrogen load of the overall system watershed by +5.3% over the MEP system load, while the system unattenuated load increased by a smaller percentage (+2.3%) (**Table 5**). Most of the changes were due to increased impervious surface loads, but fertilized lawns also increased +21%. Watershed wastewater loads decreased slightly (-4%), which may be due to changes in demographics[18] or may be due to lower water use due to lower flow toilets. The relatively higher increase in the attenuated loads was due to changes in spatial distribution of the loads within the watershed with relatively greater loading increases in the upper, eastern portion of the watershed (*i.e.*, the Centerville East subwatershed) which has higher attenuation.

The proposed Town Wastewater Plan includes provisions to connect large portions of the Centerville River watershed to a municipal sewer system (see **Figure 4**). All of the collected wastewater within the watershed would be sent to the Hyannis WPCF, effectively removing the associated wastewater nitrogen from the Centerville River watershed. The nitrogen loads associated with the 2019 Town Wastewater Plan significantly decreased the attenuated updated load by 41% with the majority of the decrease occurring within the Centerville East subwatershed (see **Table 5**).

The MEP used the watershed nitrogen loads with estimates of atmospheric nitrogen deposition on the estuary surface and measured nitrogen regeneration from the estuary sediments (*i.e.* benthic flux) as inputs to a water quality model that also used the hydrodynamics of this system based upon its bathymetry and tidal changes (**Table 6**). This MEP Linked Watershed-Embayment Nitrogen Management Model was calibrated and validated against multiyear water quality data collected at various monitoring stations in order to provide a predictive tool for future nitrogen management strategies. These results were compared to other measurements throughout the Centerville River system, including dissolved oxygen and habitat quality, to understand which portions of the system were nitrogen impaired and what target threshold nitrogen concentrations were needed to be attained to restore the water and habitat quality throughout the system. The MEP team selected a threshold water quality target of 0.37 mg/L total nitrogen (TN) for monitoring station BC-T (near the confluence of Bumps River and Centerville River) and target ranges of 0.4 to 0.5 mg/L TN at stations BC-3 in Scudder Bay and BC-7 near the Centerville River bridge. Estimates of nitrogen loads to attain these targets were developed and incorporated in the MassDEP TMDL for Centerville River.[19]

Using the MEP water quality model, TN concentrations throughout the system were updated based on the 2019 updated land use and the updated land use plus with the projected reduction in nitrogen

[18] US Census estimates of Town population have decreased by 7% since 2000, housing units counted as seasonal has increased by 3%, and the percentage of the population 65 years old or older (*i.e.*, less children in households) has increased by ~10% (www.census.gov accessed 9/19/19).

[19] MassDEP. 2007. Centerville River-East Bay System TMDLs for Total Nitrogen (Report # 96-TMDL-14, Control # CN248.0).

loads associated with the Town's Wastewater Plan (**Table 7**). The increased nitrogen loads resulting from the 2019 updated land use resulted in increased nitrogen concentrations throughout the system with the largest increase (+2.5%) in Scudder Bay. In contrast, the reduced nitrogen loads estimated from the proposed Wastewater Plan showed significant water column TN levels reductions throughout the system and, most importantly, attained the target TN concentrations at all three of the threshold stations. The results indicate that the 2019 Wastewater Plan when fully implemented for the Centerville River watershed is sufficient to restore water and habitat quality throughout the estuary.

III.3. Lewis Bay/Hall Creek Scenarios: Updated Current Conditions and Town Wastewater Plan Results

The final MEP assessment report on the Lewis Bay and Halls Creek estuary systems was completed in 2008. The MEP watershed nitrogen loading model was based on 2004 digital parcels and land use data obtained from the watershed towns of Barnstable and Yarmouth. Tidal data, bathymetry, and shoreline configuration for the Lewis Bay and Halls Creek MEP water quality models were collected in 2004 and water quality data that was used was collected between 2001 and 2006. Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that portions of the system ranged in condition from significantly impaired (Inner and Outer Lewis Bay, Uncle Roberts Cove) to moderately impaired (Hyannis Inner Harbor, Mill Creek).[20] Halls Creek, on the other hand, had measurements that were consistent with a high quality, unimpaired, salt marsh system.

The MEP team recommended target total nitrogen concentrations for Lewis Bay to address the observed impairments and used the MEP Linked Watershed-Embayment Nitrogen Management Model to develop a potential watershed nitrogen reduction option to attain the target TN concentrations needed to restore water and habitat quality. A similar step was completed for Halls Creek, but this assessment involved adding additional nitrogen up to a threshold limit greater than that measured to date, but consistent with maintaining a healthy salt marsh system (*i.e.* this salt marsh system does not need nitrogen remediation, it is below its nitrogen loading threshold). In 2015, MassDEP/EPA finalized a TMDL that included nitrogen loading limits for six impaired Lewis Bay segments: Hyannis Inner Harbor, Lewis Bay, Uncle Robert's Cove, Mill Creek, Mill Pond Creek, and Inner Harbor Creek.[21] Three other segments had "pollution prevention" nitrogen TMDL limits developed, but were not classified as impaired: Snow's Creek, Stewart's Creek, and Chase Brook. A pollution prevention TMDL was also established for Halls Creek based on the level of watershed loading and health status at the time (MEP "Present Conditions").

The updated 2019 current watershed loading for both Lewis Bay and Halls Creek utilized the data inputs discussed above. As noted, the Hyannis WPCF and the extensive sewer system are an important factor in the amount and distribution of watershed nitrogen loading. The 2019 nitrogen loading updates, included updates on the performance of the Hyannis WPCF (*i.e.*, effluent flows and total nitrogen concentrations), as well as the connection of additional properties to the sewer system since the MEP analysis. Other notable changes in the update were: 1) more refined accounting of impervious surfaces (*e.g.*, road surfaces, building areas, parking lots) and 2) changes in land use (*e.g.*, changes in uses for many of the commercial properties).

[20] See Table VIII-1 in Lewis Bay MEP Report (Howes and others, 2008).

[21] MassDEP. 2015. Lewis Bay System and Halls Creek TMDLs for Total Nitrogen (Report # 96-TMDL-18 Control #314).

Unlike Centerville River and Three Bays, the Hyannis WPCF reduces watershed nitrogen loads to Lewis Bay and Halls Creek because of higher treatment levels for wastewater collected within the watersheds, but it also adds nitrogen load because it imports wastewater from outside of the watershed, treats it, and discharges the treated effluent within the watershed to Lewis Bay. As indicated in **Table 2**, the Hyannis WPCF under both the MEP and the 2019 updated conditions scenario receives wastewater flow from sources within the Lewis Bay, Halls Creek, Centerville River, and Barnstable Harbor watersheds. Under the proposed Town 2019 Wastewater Plan scenario, the Hyannis WPCF will treat wastewater flow from all four of the Barnstable watersheds reviewed, as well as from the Yarmouth portion of the Lewis Bay watershed (see **Figure 4**). Based on Town staff direction, the effluent discharge at the WPCF site in the 2019 Plan scenario is limited to 2.0 MGD (with a TN concentration of 3.0 mg/L), all effluent from Yarmouth is returned to Yarmouth (0.62 MGD) for discharge, and any Barnstable volumes greater than 2 MGD are discharged within the Barnstable Harbor watershed (1.2 MGD). The discharge site within the Barnstable Harbor watershed is undefined at this point, but the discharge location was selected as occurring within subwatershed #20 (Barnstable Harbor LT10 Mid) and the volume and treatment level at the Hyannis WPCF results in an associated total load of 4,995 kg TN/yr.

The 2019 updated Lewis Bay current conditions increased the attenuated nitrogen load from the overall system watershed by +8.4% over the MEP system load, while the system unattenuated load increased by +6.7% compared to the MEP load (**Table 8**). The 2019 updated attenuated watershed nitrogen load to Halls Creek increased by +6.4% over the MEP system load (**Table 9**). Most of the changes were due to increased impervious surface loads, but there was also an increase in the Hyannis WPCF nitrogen loading (largely due to an increase in the effluent TN concentration under 2019 current conditions). The relatively higher increase in the attenuated loads was due to changes in the spatial distribution of the loads within the watershed with relatively greater loading increases in subwatersheds that discharge directly to the estuary and do not have attenuation during transport due to passage through streams and/or ponds (*i.e.*, the Main Bay subwatershed).

The proposed 2019 Town Wastewater Plan includes provisions to a) increase wastewater collection within the Lewis Bay watershed for treatment at the Hyannis WPCF, b) improve TN levels in the Hyannis WPCF effluent (current levels average 5.64 mg/L TN, while the Plan targets 3 mg/L TN), c) increase the wastewater volume treated at the Hyannis WPCF including import of wastewater from outside of the Lewis Bay watershed, and d) distribute most of the additional treated effluent to watersheds not associated with Lewis Bay. The Lewis Bay nitrogen loads associated with the 2019 Town Wastewater Plan significantly decreased the attenuated 2019 updated load by -43% with the majority of the decrease occurring within the Main Bay subwatershed (see **Table 8**). The Halls Creek nitrogen loads associated with the 2019 Town Wastewater Plan also decreased the attenuated 2019 updated load by -14% with all of the decrease within the watershed portions that discharge directly into the salt marsh/estuary (see **Table 9**).

The MEP used the watershed nitrogen loads with estimates of atmospheric nitrogen deposition on the estuary surface and measured nitrogen regeneration from the estuary sediments (*i.e.* benthic flux) as inputs to the MEP Linked Watershed-Embayment Nitrogen Management Model that also accounts for hydrodynamics based upon measurements of bathymetry and tidal changes throughout the estuarine system (**Table 10**). This model was calibrated and validated against water quality data collected at various monitoring stations throughout the estuary in order to provide a predictive tool for future nitrogen management strategies. These results were compared to other

measurements throughout the Lewis Bay and Halls Creek systems, including dissolved oxygen, macroalgae, chlorophyll *a* and benthic animal communities, to understand which portions of the system were impaired and what target threshold nitrogen concentrations needed to be attained to restore the water and habitat quality throughout the system. Based on the site-specific data, the MEP team selected a Lewis Bay threshold water quality target of 0.38 mg/L total nitrogen (TN) for monitoring station BHY-3, 0.4 mg/L TN in Uncle Roberts Cove (monitoring station BHY-4), and 0.5 mg/L in Hyannis Inner Harbor (average) and Mill Creek. Since Halls Creek had high quality salt marsh habitat at the time of the MEP assessment, the threshold target TN concentration was 1.0 mg/L TN at monitoring station BC-14 (this is approximately 2X the average MEP measured concentration). Estimates of nitrogen loads to attain the nitrogen concentrations thresholds were developed and incorporated in the MassDEP TMDL for Lewis Bay/Halls Creek.[22]

Using the MEP Linked Watershed-Embayment Nitrogen Management Model, TN concentrations throughout the Halls Creek and Lewis Bay Estuaries were determined for the nitrogen loads from the 2019 updated land use and the loads associated with the Town's 2019 Wastewater Plan (**Table 11**). The increased nitrogen loads resulting from the 2019 updated land use resulted in small increases in the nitrogen concentrations throughout the Lewis Bay system with the largest increases in Snow Creek (+11% at BH-4) and the outermost station in Hyannis Inner Harbor (+4.5% at BH-3). In contrast, the reduced nitrogen loads estimated from the 2019 proposed Wastewater Plan showed significant reductions throughout the system and, most importantly, attained the target TN concentrations at all five of the Lewis Bay threshold stations. In Halls Creek, the changes in the Town's 2019 proposed Wastewater Plan slightly reduced the TN concentration at the sentinel monitoring location and remained well below the TMDL threshold concentration. The results indicated that the 2019 Wastewater Plan, when fully implemented, will lower nitrogen inputs sufficiently to attain the TN threshold and restore water and habitat quality throughout the Lewis Bay Estuary, while continuing to provide adequate protection for Halls Creek. When fully implemented both Halls Creek and Lewis Bay estuarine systems will support high water and habitat quality.

III.4. Barnstable Great Marshes/Bass Hole Scenarios: Updated Current Conditions and Town Wastewater Plan Results

The final MEP assessment report on the Barnstable Great Marshes estuary system was completed in 2017, so it is easily the most recent of the Barnstable MEP reports and, as such, the system likely to have the smallest change in watershed nitrogen loads. The MEP watershed nitrogen loading model was based on digital parcels and land use data with base years between 2011 and 2012 that were obtained from the watershed towns of Barnstable, Yarmouth, Dennis, and Sandwich. Bathymetry and salt marsh topography for the Barnstable Great Marshes MEP water quality model were collected in 2015 and 2013, respectively. Water quality data between 2002 and 2014 was used in the development of the model. Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that the majority of the system had healthy habitat except for the Millway subembayment, which is a dredged boat basin with severely degraded habitat.[23] The MEP team recommended a target bioactive nitrogen concentration at the Millway to address its measured nitrogen-related impairments, but found that the majority of the Great Marshes system could accommodate a +39.6% increase in watershed nitrogen loads without

[22] MassDEP. 2015. Lewis Bay System and Halls Creek TMDLs for Total Nitrogen (Report # 96-TMDL-18 Control #314).

[23] See Table VIII-1 in Barnstable Great Marshes/Bass Hole MEP Report (Howes and others, 2017).

becoming impaired.[24] MassDEP has not developed a draft nitrogen TMDL for Barnstable Great Marshes or the Millway.

The 2019 current watershed loading utilized the updated data inputs discussed above. Portions of Barnstable Village, including parcels within the Millway subwatershed, are connected to the municipal sewer system and the Hyannis WPCF. The 2019 current conditions nitrogen loading update, included increases in the number of parcels connected to the municipal sewer system (+27), use of more complete accounting of impervious surfaces (*e.g.*, road surfaces, building areas, parking lots) and changes in land use (*e.g.*, changes from undeveloped to developed lots). Overall, the total system unattenuated and attenuated loads in the 2019 update changed the corresponding MEP loads by less than 1%.

The proposed Town 2019 Wastewater Plan includes provisions to a) collect more wastewater within the Barnstable Great Marshes watershed for treatment at the Hyannis WPCF, b) return of treated effluent from the Hyannis WPCF (at 3 mg/L TN) for discharge within the Great Marshes watershed, and a significant reduction (-53%) in wastewater nitrogen loads within the Millway subwatershed. Overall, the nitrogen loads associated with the Town Wastewater Plan increased the attenuated updated total watershed load to the Great Marshes system +1.3% (**Table 12**).

The MEP used the watershed nitrogen loads with estimates of atmospheric nitrogen deposition on the estuary surface and measured nitrogen regeneration from the estuary sediments (*i.e.* benthic flux) as inputs to a water quality model that also accounted for estuarine hydrodynamics based upon the bathymetry and tidal changes throughout the Barnstable Great Marshes system (**Table 13**). This model was calibrated and validated against water quality data collected at various monitoring stations in order to provide a predictive tool for future nitrogen management strategies. These results were compared to other measurements throughout the Barnstable Great Marshes system, including dissolved oxygen, chlorophyll, eelgrass, macroalgae and benthic animal communities, to understand which portions of the system were impaired and what target threshold nitrogen concentrations were needed to support high water and habitat quality throughout the estuary. The MEP team selected a threshold water quality target of 0.16 mg/L bioactive nitrogen (bioN) for three sentinel stations in the salt marsh-dominated basins and a 0.21 mg/L bioN threshold in the Millway basin. Bioactive N[25] was selected for the development of the threshold because other portions of the nitrogen pool appeared to be biologically inactive (*i.e.*, refractory) with similar concentrations inside and outside of the system.[26] Average bioN concentrations in the main basins of the Great Marshes were below the 0.16 mg/L bioN threshold, while average concentrations in the Millway were above the 0.21 mg/L bioN threshold.

Using the MEP Linked Watershed-Embayment Nitrogen Management Model, bioN concentrations throughout the system were determined for the nitrogen loads from the 2019 updated watershed land use and also for the loads associated with the Town's 2019 Wastewater Plan coupled with the 2019 updated land use (**Table 14**). The slightly increased nitrogen loads resulting from the 2019 updated land use generally resulted in small increases in nitrogen concentrations throughout the system (+0.2% to +1.7%), but there was a -5.6% decrease in the

[24] See Table VIII-3 in Barnstable Great Marshes/Bass Hole MEP Report (Howes and others, 2017).

[25] Bioactive N = ammonium, nitrate+nitrite, and the particulate organic nitrogen comprised primarily of phytoplankton (live and dead).

[26] This approach was also applied in the MEP assessment of Pleasant Bay.

Millway bioN concentration largely due to increased sewering of properties within its watershed. This decrease was insufficient to attain the MEP bioN threshold. In the proposed 2019 Wastewater Plan, the addition of an alternative wastewater discharge from the Hyannis WPCF within the watershed caused increased bioN concentrations throughout the overall system (+0.7% to +7.0%), but expanded sewering within the Millway watershed resulted in a significant decrease (-46.7%) in the Millway basin bioN concentration. This decrease in concentration resulting from the proposed changes in the 2019 Wastewater Plan allowed the Millway basin to attain the 0.21 mg/L bioN threshold concentration needed for water and habitat quality restoration. While the 2019 Wastewater Plan resulted in increases in bioN concentrations throughout the rest of Great Marshes system, the concentrations all remained below the bioN threshold concentrations. Overall, the proposed 2019 Wastewater Plan attained the bioN threshold concentrations at all four of the Barnstable Great Marshes threshold stations.

III. Conclusions/Discussion

At the request from the Town of Barnstable, project staff updated the watershed land use portions and associated nitrogen loads for MEP linked models for the following systems: Three Bays, Centerville River, Lewis Bay/Halls Creek, and Barnstable Great Marshes. The updated nitrogen loads were combined with the existing MEP hydrodynamic/water quality models, which were not updated, and the resulting nitrogen concentrations were compared to the MEP nitrogen thresholds/MassDEP TMDLs. Updating the 2019 current condition watershed nitrogen loads showed increased watershed nitrogen loads to all estuaries, due to increases in development, increased impervious surfaces, and in Hyannis, increased nitrogen loads from the Water Pollution Control Facility (WPCF). As a result, all systems remain impaired, having portions with watershed nitrogen loads and water column nitrogen concentrations in excess of the approved TMDLs and MEP thresholds.

The Town has proposed a 60-year, three-phased wastewater plan that uses and builds on the existing wastewater infrastructure, including the municipal Hyannis WPCF. Using the updated 2019 land uses, project staff also reviewed the impact of the proposed 2019 wastewater plan when fully implemented on the watershed nitrogen loads and the associated nitrogen concentrations in the Town's major estuaries. These scenarios incorporated the proposed sewering in each of the watersheds, along with the proposed distribution of treated effluent from the Hyannis WPCF. These scenarios also utilized the existing MEP hydrodynamic/water quality models without any updates to tidal measurements, sediment nitrogen regeneration or bathymetry. In most of the systems, the proposed Town wastewater plan resulted in the TMDLs/MEP thresholds being attained. The proposed strategy for the Three Bays system of sewering as put forward in the 2019 Wastewater Plan will require implementation of further nitrogen management, currently being planned, to attain the necessary nitrogen loading reductions to fully restore the water and habitat quality throughout the Three Bays Estuary.

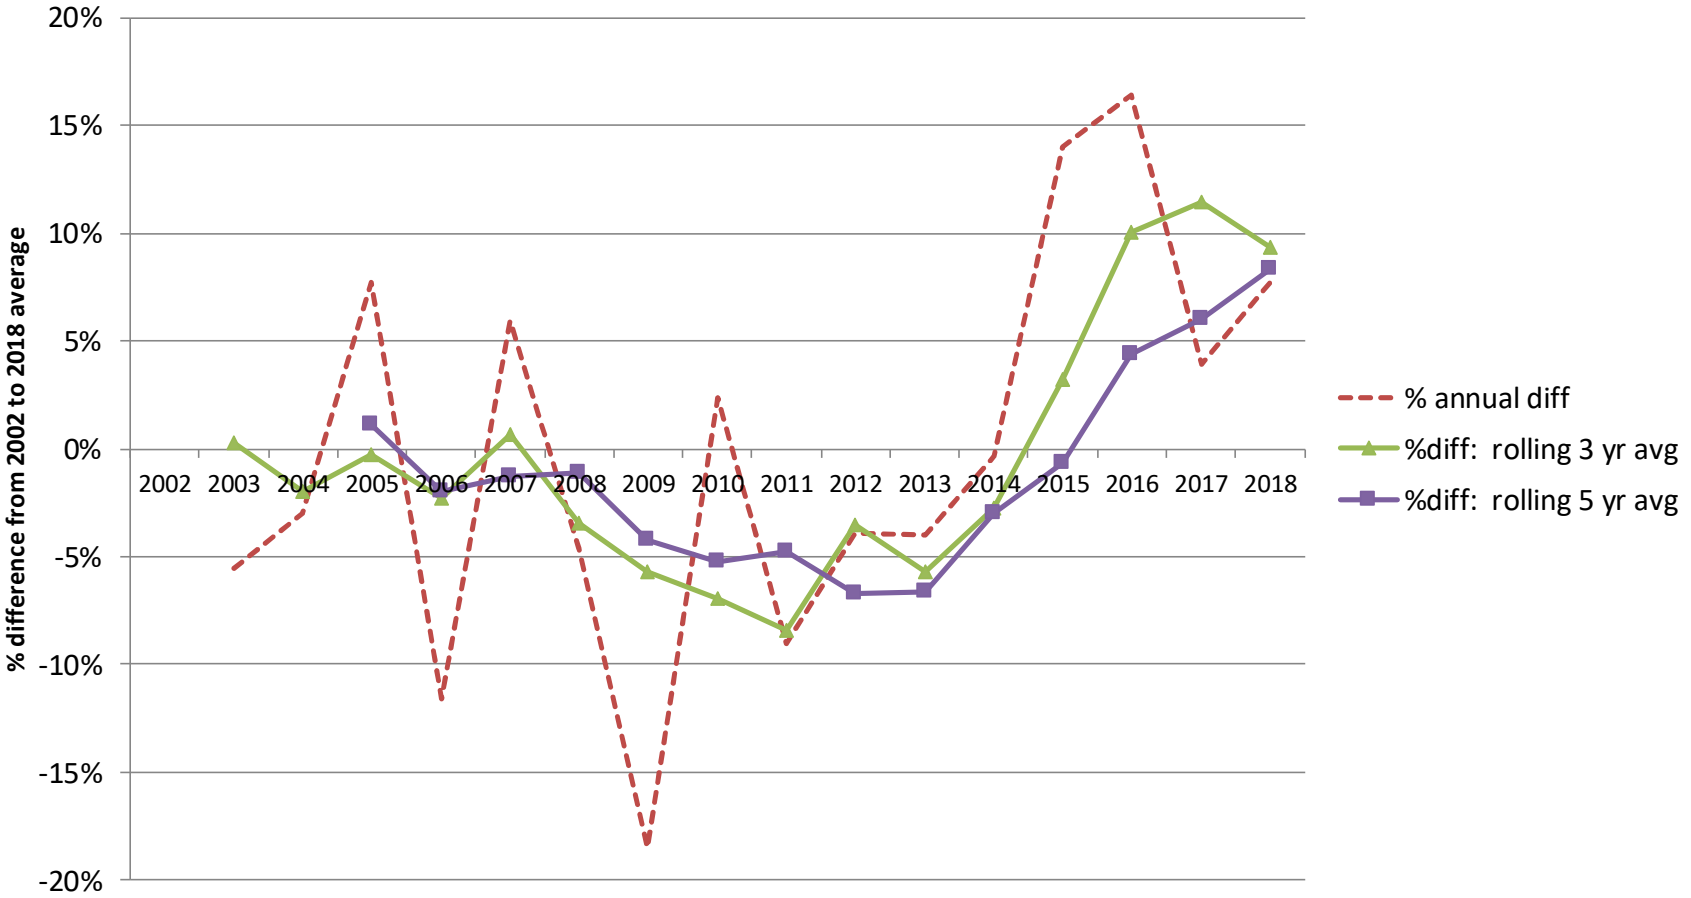

Figure 1. Annual Water Use Fluctuations and Rolling Averages: COMM Example. Town-wide water uses vary from year depending on irrigation needs and precipitation. In order to use water use as a proxy for wastewater generation, these fluctuations are generally smoothed out by averaging water uses over a number of years, which is also more reflective of groundwater processes, such as time of travel and flow path variability. Working with Town staff, project staff reviewed annual water uses for each of the public suppliers and selected an averaging period of 2011 to 2016 for the updating of the MEP watershed nitrogen loading models, as well as the evaluation of the estimated nitrogen loads associated with the Town Wastewater Management Plan. This graph shows how annual averages fluctuate significantly from year to year (red dashed line) for COMM, the largest water supplier within the Town. Rolling averages of 3 year and 5 year periods show below average water use from 2009 to 2013, an average year in 2014, and above average years from 2015 to 2018. The averaging period from 2011 to 2016 generally balances the below average years prior to 2014 with the subsequent above average years.

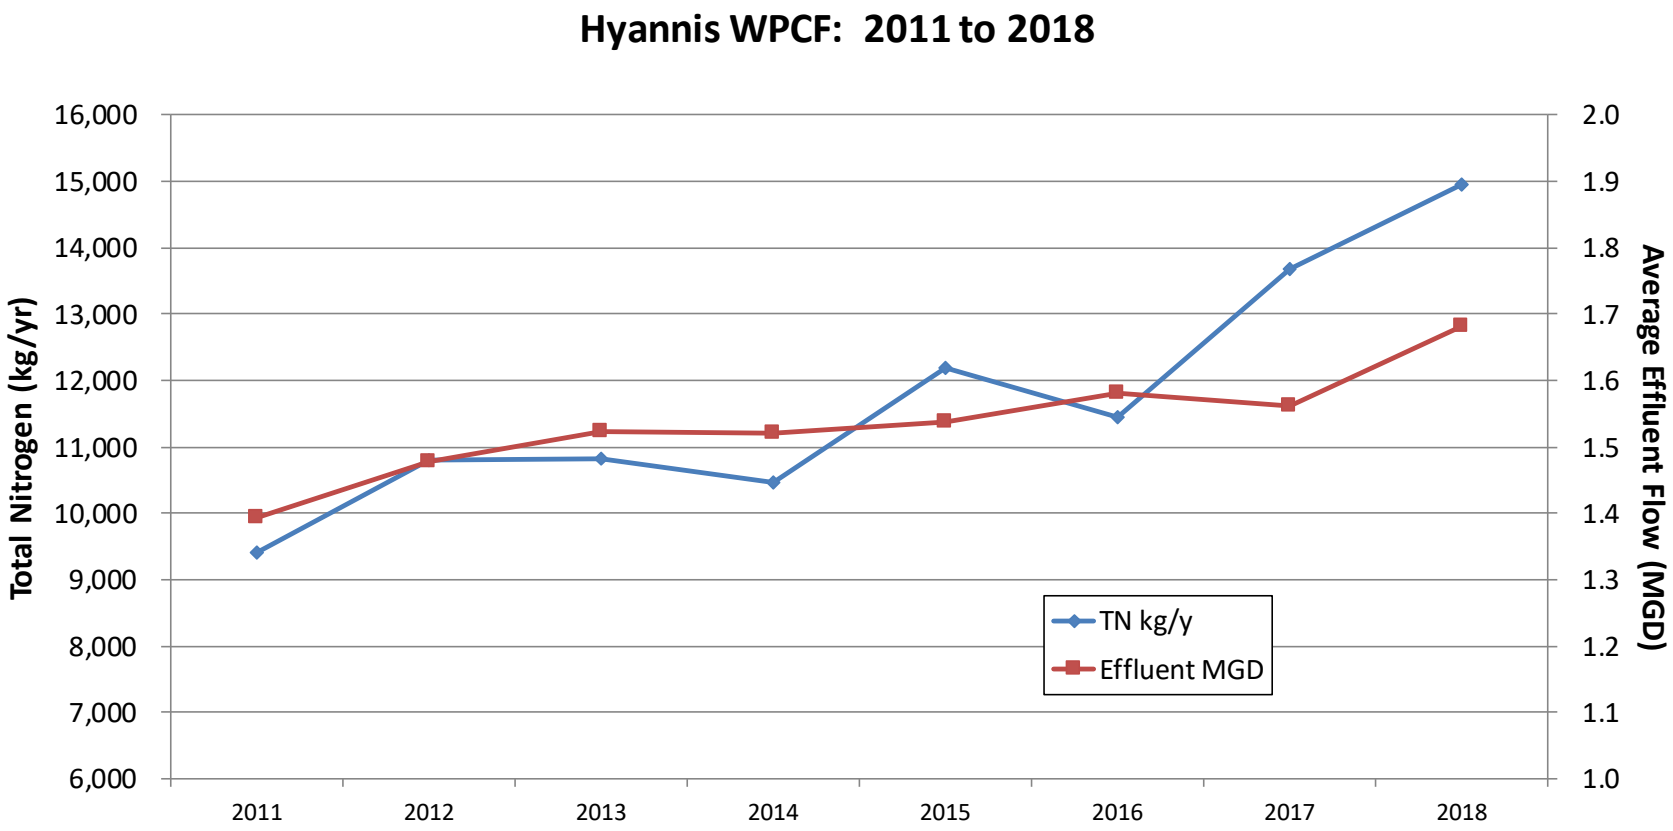

Figure 2. Hyannis Water Pollution Control Facility: Annual Nitrogen Load and Average Daily Effluent Flow (2011 to 2018). Based on data from the Town, the nitrogen load produced by the Hyannis WPCF increased at an average annual rate of +6% (R2=0.83), while effluent discharged increased by +2% per year (R2=0.86). Effluent flows were compared to water use from parcels within the sewer collection area as a QC step for the watershed nitrogen loads. This comparison found some issues that will require additional attention by the Town, but these generally were small. The increasing trends in flow and nitrogen load should be considered in near future projections of impacts. The existing conditions scenarios completed for this project utilized an average of the most recent three years (2015 to 2018), which resulted in an average effluent TN concentration of 5.95 mg/L TN, while the Wastewater Plan scenario based on direction from Town staff assumed that the WPCF effluent had an average effluent TN concentration of 3 mg/L TN.

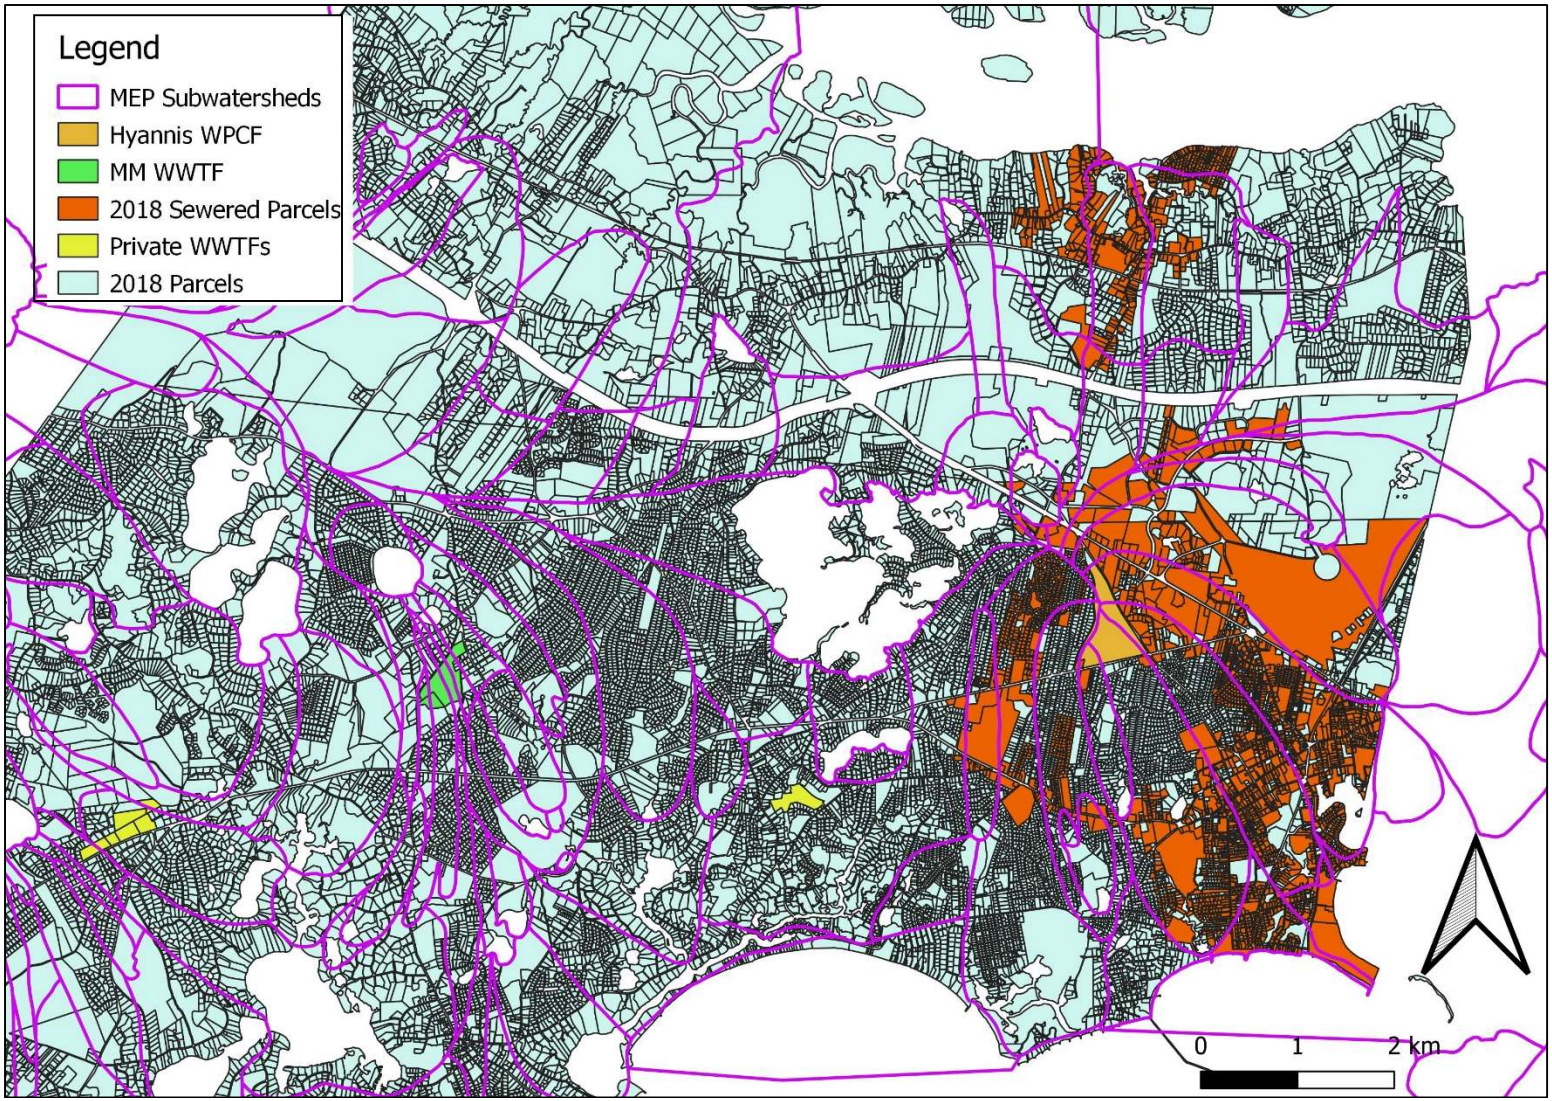

Figure 3. Current Sewered Parcels and Wastewater Treatment Facilities: Town of Barnstable (2018). Based on data supplied by the Town, parcels currently connected to the municipal sewer system are shown in orange. The collected wastewater from these parcels is treated and discharged at the at the Hyannis WPCF (shown in light orange). The Town also operates another municipal treatment facility (shown in green). The location of the two private treatment facilities within the study area are shown in yellow. All other wastewater on developed properties is treated by on-site septic systems.

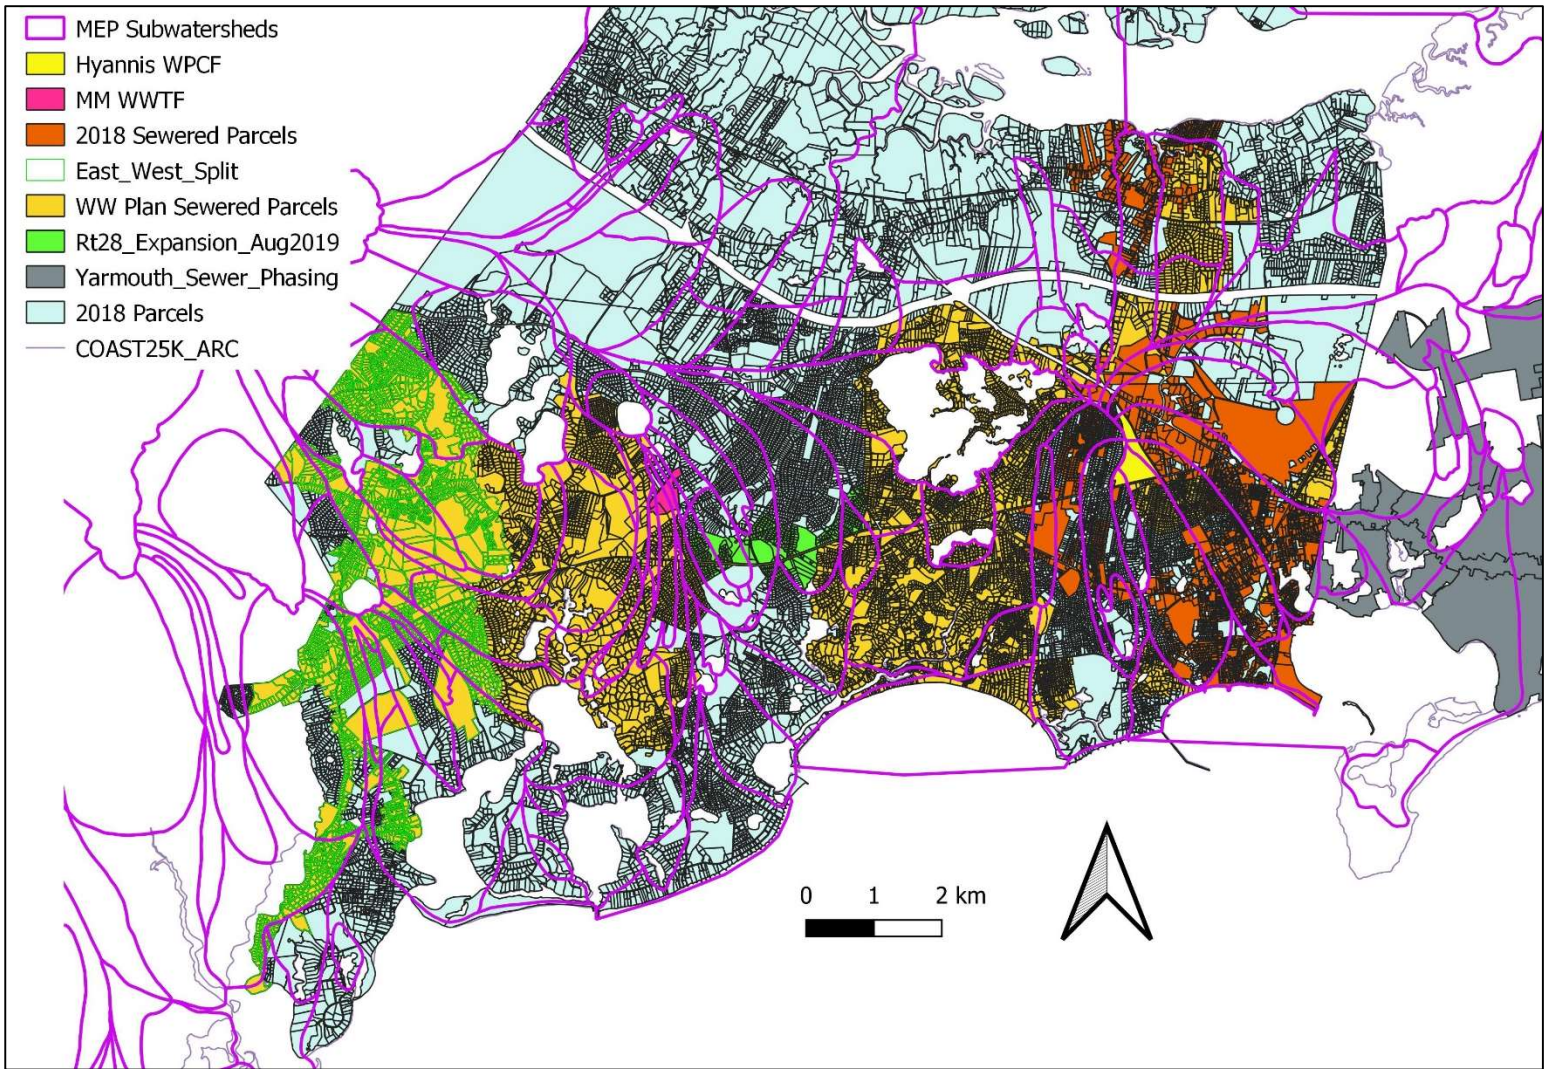

Figure 4. 2019 Town of Barnstable Wastewater Plan: Planned Sewered Parcels. Based on Town data, orange parcels are currently connected to the municipal sewer system, while yellow parcels will be connected in the future under the Wastewater Plan (including two current private treatment plants). In August 2019, the Town added: a) sewering of the green parcels along Route 28 in Centerville and b) different treatment for future sewered parcels in the Three Bays and Popponesset Bay watersheds (parcels outlined in green). Wastewater flow from green-outlined parcels (~0.45 MGD) will be treated and discharged at an as-yet-undetermined site outside of the town boundaries. Also shown are planned Yarmouth sewered areas; wastewater flow (~0.26 MGD) will be treated at the Hyannis WPCF and discharged outside of the Lewis Bay watershed. All other wastewater on developed properties will continue to be treated by on-site septic systems.

Table 1. Wastewater Treatment Facilities within the Barnstable Wastewater Plan study area watersheds. Within the four estuary watersheds reviewed in this project, there are two municipal wastewater treatment facilities and two private facilities. Based on data provided by the Town and MassDEP, project staff updated the associated nitrogen loads for each facility. The Hyannis Water Pollution Control Facility (WPCF) is by far the largest of the facilities (*e.g.*, N load >250X greater than next largest). In the current Wastewater Plan, the two sites with private facilities would be connected to the WPCF sewer system. In addition, the WPCF would treat a substantially greater volume (1.47 MGD is treated under current conditions, while 3.82 MGD will be treated under the Wastewater Plan), but effluent discharge would be distributed to other sites (effluent on the WPCF site would be limited to 2.0 MGD).

Table 2. Watershed Nitrogen Loads for Three Bays Scenarios: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan. The 2019 update of watershed parcels, water use, impervious surfaces, etc. increased the attenuated nitrogen load of the overall system watershed by 5.5% and the unattenuated load by 0.8% compared to the MEP loads. Most of the changes were due to increased impervious surface loads, which were somewhat offset by decreased wastewater loads. The relatively increased attenuated loads were due to relatively greater impervious surface increases in the lower portion of the watershed. The proposed Town Wastewater Plan would decrease the attenuated load by 44% with the majority of the decrease within the Prince Cove subwatershed. These loads do not include nitrogen deposition on the estuary surfaces.

Table 5. Watershed Nitrogen Loads for Centerville River Scenarios: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan. The 2019 update of watershed parcels, water use, impervious surfaces, etc. increased the attenuated nitrogen load of the overall system watershed by 5.3% and the unattenuated load by 2.3% compared to the MEP loads. Most of the increased loads were due to increased impervious surface loads, which were somewhat offset by decreased wastewater loads. The relatively increased attenuated loads were due to relatively greater impervious surface increases in the upper portion of the watershed (Centerville East). The proposed Town Wastewater Plan would decrease the attenuated load by 41% with the majority of the decrease within the Centerville East subwatershed. These loads do not include nitrogen deposition on the estuary surfaces.

Table 8. Watershed Nitrogen Loads for Lewis Bay Scenarios: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan. The 2019 update of watershed parcels, water use, impervious surfaces, additional sewer connections, etc. increased the attenuated nitrogen load of the overall system watershed by 8.4% and the unattenuated load by 6.7% compared to the MEP loads. Most of the changes were due to increased impervious surface loads, but there was also increases in the WPCF load. Most of the increase was in the Mill Creek and Inner Harbor subwatersheds. The proposed Town Wastewater Plan would decrease the attenuated load by 43% with the largest decrease in the Main Bay subwatershed (shed #16). These loads do not include nitrogen deposition on the estuary surfaces.

Table 9. Watershed Nitrogen Loads for Halls Creek Scenarios: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan. The 2019 update of watershed parcels, water use, impervious surfaces, additional sewer connections, etc. increased the attenuated nitrogen load of the overall system watershed by +6.4% and the unattenuated load by +6.6% compared to the MEP loads. Most of the changes were due to increased impervious surface loads, but there was also an increase in the WPCF load. Most of the increase was in the portion of the watershed that discharges directly to the estuary/salt marsh system. The proposed Town Wastewater Plan would decrease the attenuated load by -14%. These loads do not include nitrogen deposition on the estuary surfaces.

Table 11. Comparison of modeled average total N concentrations for Lewis Bay and Halls Creek: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan Scenarios. The Lewis Bay sentinel station threshold is 0.38 mg/L TN at BHY-3 monitoring station with secondary threshold targets of 0.4 mg/L TN for eelgrass restoration in Uncle Roberts Cove and 0.5 mg/L in Mill Creek (MC-1) and an average of the two Hyannis Harbor stations (BH-1 and BH-2) to restore healthy infaunal habitat; these monitoring stations and threshold targets are shown in **bold** print. 2019 Wastewater Plan scenario attains the Lewis Bay threshold targets at the selected monitoring stations, needed for restoration of estuarine habitat and water quality.

Halls Creek has a higher threshold (1 mg/L TN) as a healthy salt marsh system and has TN concentrations at the sentinel station (BC-14) that are less than this threshold at the time of the MEP assessment and remain so under the 2019 scenarios with the land use update and the planned Wastewater Plan.

Table 12. Watershed Nitrogen Loads for Barnstable Great Marshes Scenarios: MEP, 2019 Land Use Update, Town of Barnstable Wastewater Plan. The 2019 update of watershed parcels, water use, impervious surfaces, additional sewer connections, etc. had negligible impact on the overall unattenuated and attenuated system loads (<1% change), although the impervious surface load increased due to the more comprehensive accounting of these land uses. The proposed Town Wastewater Plan would increase the attenuated system load by 1.3%, but would decrease the Millway subwatershed load by 53%. *Millway is part of Great Marsh East subwatershed and was the only impaired portion of the Great Marsh system that was identified in the MEP assessment. These loads do not include nitrogen deposition on the estuary surfaces.

Ed Eichner, MEP Watershed Lead for CSP-SMAST and TMDL Solutions

Re: **Update on Watershed nitrogen loading and TMDL N thresholds at present and post-wastewater improvements for Barnstable estuaries: Three Bays, Centerville River, Lewis Bay and Barnstable Great Marshes.**

Date: October 8, 2019

****

This Tech Memo is being provided as an update on the nearly completed full watershed N loading updated analysis (completed) and water quality modeling (underway) of the 4 major Barnstable estuaries: Three Bays, Centerville River, Lewis Bay and Barnstable Great Marshes, and the loading reductions from proposed wastewater system implementation as developed by the Barnstable DPW. The watershed loading update and wastewater N loading reduction was developed as a joint effort between engineers within Barnstable DPW and SMAST scientists.

CSP-SMAST scientists analyzed updated land-use data from 2018 and average water uses, which is used as a proxy for wastewater generation, based on 2011 to 2016. These updates were extensive for Three Bays, Centerville River, Lewis Bay, which were completed for the MEP based on data from 2000 to 2004. The Barnstable Great Marshes MEP assessment was based on 2011 to 2012 data The land-use data was integrated with parcel based on average water use to yield the updated parcel based watershed N loads. The updated watershed N loads were then used in the MEP linked watershed-embayment management model to assess changes in projected nitrogen concentrations throughout each of the 4 Barnstable estuaries. The MEP hydrodynamic module and sediment regeneration rates, after adjustment to the new N loading, were used as the other inputs into the linked model.

In addition to updating the watershed N loading, the Barnstable DPW provided details for the Wastewater Implementation Scenarios for each of the 4 Barnstable estuaries, including the planned sewer areas, targeted effluent N concentrations and volumes and locations for discharge of treated effluent for the extensive use of the Hyannis WPCF. These post-wastewater implementation watershed loads were then used as input into the newly updated Linked Models. These loads were used to project changes in nitrogen concentrations throughout the 4 Barnstable estuaries relative to the nitrogen threshold targets put forward by EPA/DEP in the available TMDL's under the Clean Water Act, specific to each estuary.

While this is a preliminary analysis based primarily on the new watershed loads for present and post-wastewater implementation scenarios, there are some clear results relative to meeting the N loading targets specific to each estuary for restoration of water and habitat quality. Based upon the analysis to date, it appears that the Centerville River Estuary and the Lewis Bay Estuary should meet their restoration N targets once the Town's wastewater plan is fully implemented. The post-wastewater implementation N loads in both cases appears to be sufficiently below the TMDL target load so that the TMDL threshold TN concentration at the Sentinel Station should be met. This is particularly likely as the Linked Model when complete with the new watershed nitrogen loads also "adjusts" the sediment nitrogen regeneration for the new lower watershed loading and lower

phytoplankton production under that loading. This should further lower the final TN concentrations relative to the TMDL N threshold level.

The Barnstable Great Marshes as a whole are far below their acceptable restorative threshold watershed N load and TN threshold concentration at present. Wastewater N removals through sewers and WWTF treatment is targeted primarily on the loads to the Barnstable Harbor boat basin/Millway basin which are the small portion of this large estuary which are currently showing some nitrogen related impairments, primarily to benthic animal habitat. It does appear that the sewer plan when implemented will significantly reduce the N load to this small tributary basin.

Finally, the Three Bays Estuary may be slightly above its watershed TMDL target with implementation of the Town's wastewater plan alone. However, it should show significant improvement throughout its basins, with most of its tidal reaches fully restored. However, the Town's wastewater plan needs to be evaluated in the context of other watershed nitrogen removal efforts (Mill Pond restoration, Hamblin Bogs restoration/enhanced N removal, implementation of targeted I/A systems within the Marstons Mills River sub-watershed, and possible PRB installation, etc) as well as in estuary N removal through targeted shellfish aquaculture. Given that the watershed N load is close to the TMDL target, it is also possible that the Linked Model output will be even closer (if not achieve) the N concentration threshold at the Sentinel Station when the updated sediment regeneration rates for post-wastewater implementation are incorporated into the Linked Models. As noted above, sediment regeneration is a response to the level of phytoplankton production in these shallow estuaries, like Three Bays. Phytoplankton production is a direct result of nitrogen levels (controlled by watershed N loading and flushing). Therefore, as watershed N loading is lowered, estuarine N levels decline and there are less phytoplankton to settle and support sediment nitrogen release. This response has been directly measured in estuaries in southeastern Massachusetts, previously, by the MEP Technical Team and it a fundamental part of the MassDEP/SMAST MEP approach.

The final step in the present evaluation of these 4 estuaries and their specific wastewater plans is the completion of the Linked watershed-embayment modeling which is underway and will be completed very soon.

Memo: Greenhouse Gas Review

Appendix RR

Action Plan for the Barnstable Ponds

WRIGHT-PIERCE
Engineering a Better Environment

MEMORANDUM

TO:	Griffin Beaudoin, PE – Town of Barnstable	**DATE:**	12/3/2019
FROM:	Edward Leonard, PE	**PROJECT NO.:**	20157A
SUBJECT:	Barnstable CWMP – Preliminary GHG Emissions Review		

BACKGROUND AND PURPOSE

The Barnstable CWMP describes a Recommended Plan (significant expansion of traditional wastewater management systems supplemented by non-traditional nitrogen removal measures) and a No Action Plan (continued widespread use of septic systems without expansion of traditional wastewater management systems).

The Recommended Plan and the No Action Plan will result in continued and increased long-term electrical energy and fossil fuel use related to septic systems, I/A systems, sewer system conveyance pumping, wastewater treatment, effluent disposal and sludge disposal.

The "Revised MEPA Greenhouse Gas Emissions Policy and Protocol" (Massachusetts EOEEA, effective dated May 2010) outlines requirements for a detailed, site-specific greenhouse gas (GHG) emissions comparative analysis. However, given that there are several big-picture items that warrant further consideration (e.g., the number and location of treatment plants, the number and location of effluent disposal facilities, the extent of regionalization with abutting municipalities in shared watersheds, etc.), it is premature to complete the type of GHG emissions analysis envisioned in the policy document at this time. Instead, a preliminary GHG emissions review was conducted.

The purpose of this memorandum is to summarize the inputs and results of the preliminary GHG emissions review for the Barnstable CWMP.

APPROACH

The approach used in this preliminary GHG emissions analysis was to apply unit emission rates to the town-wide estimates of the number of septic system, the number of I/A systems and the number of sewer connections under two conditions: "pre-CWMP" and "post-CWMP". Under both conditions, growth and economic development were excluded. Said another way, this analysis identifies the change in GHG emissions associated with implementing the CWMP for the existing level of development.

UNIT EMISSION RATES

The unit emissions rates were developed based on a literature search. The basis for the unit emission rates is summarized in Attachment A.

PRELIMINARY ESTIMATE OF GHG EMISSIONS

The parameters included and excluded from this analysis are summarized in Table 1 at the end of this memorandum. The estimated number of septic systems, I/A systems, sewer connections and sewer flows under pre-CWMP and post-CWMP conditions are summarized in Table 2 at the end of this memorandum. The estimated GHG emissions under pre-CWMP and post-CWMP conditions are summarized in Table 3 at the end of this memorandum.

The town-wide estimates for the two conditions are as follows: Pre-CWMP: 10,900,000 kg CO2-eq/year; and Post-CWMP: 14,700,000 kg CO2-eq/year. The preliminary GHG emissions analysis indicates that implementation of the CWMP will result in an estimated 35% increase in GHG emissions. This is the net result of a 52% in emissions from septic systems and a 93% increase in emissions from centralized wastewater treatment.

1 Introduction and Scope

This report summarizes the current water quality and aquatic habitat conditions of many freshwater ponds located in the Town of Barnstable, Massachusetts, and recommends priority actions to ensure the ponds' protection and restoration. The Town of Barnstable is currently working with Stearns & Wheler GHD of Hyannis, Massachusetts to prepare a comprehensive nutrient management strategy that will guide the community's development in a manner that protects natural resources, including the quality of the coastal embayments, inland freshwater ponds and groundwater. This action strategy for the freshwater ponds is one component of the overall nutrient management planning project.

As summarized in the July 2008 report to the Town of Barnstable Conservation Commission prepared by the Cape Cod Commission and the Coastal Resources Group of the UMASS School of Marine Science and Technology (Eichner et al. 2008), the Town of Barnstable has 182 freshwater ponds, totaling 1,856 acres. About half of the town's freshwater ponds are extremely small, occupying less than one acre. There are 93 ponds one acre or greater in surface area. Of these, only 25 are larger than 10 acres and are consequently classified as "Great Ponds" by the state. The location of the freshwater ponds is illustrated in Figure 1, which was prepared by Town of Barnstable GIS staff.

This report sets forth recommendations to the Town of Barnstable as they integrate management of the inland ponds into an overall nutrient management plan. The recommendations consider effectiveness (both short-term and long-term), cost, permitting issues and recreational impacts. The recommended actions include institutional, technical and public education components. Some recommendations are town-wide, while others are directed to specific ponds. An overall implementation strategy is presented that defines priority actions and sequencing of recommendations.

Hamblin Pond: Recreational use

In accordance with guidance from the Massachusetts Department of Environmental Protection (MA DEP), the analysis and recommendations in this report do not provide a foundation for defining a Total Maximum Daily Load for phosphorus input to the town's freshwater ponds.

2 Nutrients and Eutrophication

> *"Lakes seem, on the scale of years or human life spans, permanent features of the landscape, but they are geologically transitory, usually born of catastrophe and mature and die quietly and imperceptibly" (Hutchinson 1957).*

This often-cited quote from a classic limnology text provides excellent context for reviewing the current and future conditions of the ponds of Barnstable. The ponds may be arrayed along a continuum from open, clear, water with little visible algal growth to extremely shallow, productive systems well on their way to becoming wetlands.

Shubael Pond – Deep, with exceptionally clear water, sandy bottom.

Aunt Betty's Pond – Ultra-shallow, very productive with submerged and floating-leaved plants evident.

Eutrophication, the term for both the process and the effects of enrichment of surface water systems (including lakes, ponds, estuaries, and reservoirs), is a significant water quality concern for many aquatic ecosystems. As aquatic systems become increasingly enriched with plant nutrients, organic matter and silt, the result is increased biomass of algae and plants, reduced water clarity, and ultimately, a reduction in volume. Aesthetic quality and habitat conditions are degraded, and affected waters may no longer be suitable for drinking water or recreation.

While eutrophication is a natural process, it can be greatly accelerated by human activities. There are numerous lakes and ponds included in state compendia of impaired waters; most are listed due to excessive nutrient inputs from nonpoint sources such as agricultural or urban runoff, or seepage from on-site wastewater disposal systems. Less frequently, the impairment of surface waters is attributed to excessive discharge of nutrients from point sources; these may be piped discharges of inadequately treated wastewater from industrial or municipal sources.

Water resources managers focus on identifying and controlling the sources of nutrients, organic material, and silt to aquatic ecosystems in an effort to slow the eutrophication process. Phosphorus is most often the limiting nutrient for primary productivity and algal growth in inland lakes and ponds. While phosphorus is the key to managing eutrophication of inland

ponds, nitrogen is usually the limiting nutrient for primary production of coastal ecosystems. Nitrogen enrichment has resulted in degradation of estuarine and marine water quality and habitat conditions, and wastewater is a major source of nitrogen. Scientists and regulators from the EPA, the MA DEP, the academic community and the Cape Cod Commission have supported the coastal municipalities in a systematic process to define the need for and extent of reductions in nitrogen loading (MA DEP 2003 "The Massachusetts Estuaries Project Embayment Restoration and Guidance for Implementation Strategies"). Findings of this analysis are now being incorporated into land use and facilities decisions across Cape Cod.

Mystic Pond (Indian Ponds)

Middle Pond (Indian Ponds)

Hamblin Pond (Indian Ponds)

3 Kettle Pond Ecosystems

Most of the inland freshwater ponds of Cape Cod are kettle ponds, formed as depressions left behind by ice blocks as the glacial ice retreated between 14,000 and 17,000 years ago. According to Portnoy et al (2001), while kettle ponds have a common glacial origin, their subsequent evolution differs based on the depth of the original ice block, landscape position relative to sea level, and the texture (particle size) of the soils in the ponds' watersheds. Cultural effects are also to be added to this list; the ponds of Cape Cod are influenced by the amount and type of development in the watershed, invasions of exotic species, application of lime to raise the naturally low pH of the waters, and fisheries management practices.

Unlike most lakes and ponds, kettle ponds do not have prominent tributary streams (inlets) and outlets (**Figure 2**). Groundwater seepage and direct precipitation, rather than surface water flows, are the source of water to the kettle ponds. The quality of the water in the ponds, therefore, is directly affected by the quality of the groundwater resource.

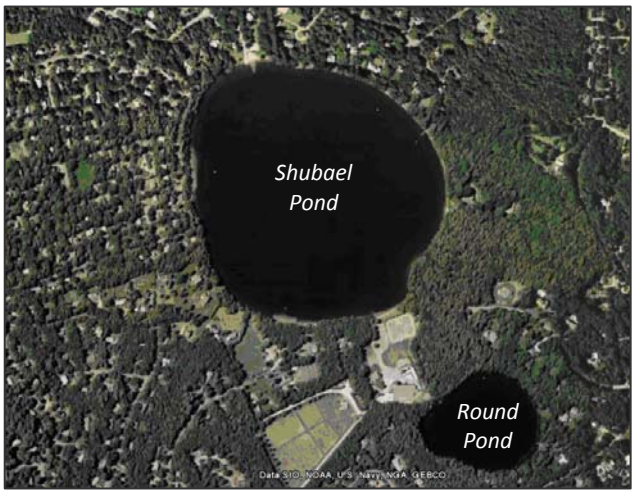

Figure 2. Aerial photograph of Shubael and Round Ponds illustrating hydrologic isolation of kettle ponds.

The lack of defined inlets and outlets for most kettle ponds has some important implications for the cycling of nutrients and organic material. Nitrogen and phosphorus enter the ponds primarily as dissolved nutrients where they are incorporated into biomass. Water leaves the ponds through groundwater seepage and evaporation. Particulate biomass consequently remains in the ponds, and the nutrients continue to cycle through the food web. Through this natural phenomenon, kettle ponds become more productive over time, as there is little opportunity for particulate material to leave the system. The Cape Cod Commission compiled dissolved oxygen (DO) measurements in the lower waters of 41 kettle ponds; data were from 1948 and 2001. Comparison of the data revealed that 76% of the measurements were lower in 2001 than 1948. These data provide strong evidence of an increasing level of productivity in the ponds over the intervening five decades (Cape Cod Commission, May 2003 p. 46).

Round Pond

Another important consideration for the kettle

ponds of Barnstable is that many of the ponds are shallow, with extensive wetland and littoral zones and macrophyte communities. Cooke et al. (1993) point out that the complexity of nutrient flux and food web interactions at the sediment-water interface in highly productive shallow regions of lakes and ponds cannot be ignored. Nutrient cycling and biological interactions in shallow, weedy sections of the ponds may contribute to maintaining elevated nutrient levels and undesirable plant growth long after external loading controls have been implemented.

Elizabeth Pond

4 Sources of Data and Information

A recent report summarizes the water quality status of the ponds of Barnstable (Eichner et al. 2008). After reviewing available data, the authors of this report concluded that:

> *"Available data for most ponds in Barnstable is limited. Other than the PALS Snapshots and sampling following the alum treatment at Hamblin Pond, sampling of most of the ponds has been sporadic. Given the sporadic available data and since the PALS Snapshots are designed to sample ponds during what is likely to be their worst water quality conditions, interpretation of available data must be approached with an understanding of these limitations."*

This Action Plan builds on the information provided in the 2008 report, and incorporates other data sources as summarized in **Table 1**. Of the 59 ponds listed in the table, data sources were available for 64% of the ponds.

May 2003.

[7]Visual assessment conducted by EcoLogic staff on July 29, 2009.

4.1 Cape Cod Commission Reports

Barnstable Ponds: Current Status, Available Data, and Recommendations for Future Activities (Eichner et al. 2008). In 2008, the Cape Cod Commission, in cooperation with the Coastal Systems Group School of Marine Science and Technology University of Massachusetts Dartmouth, issued a report on the current status, available data, and recommendations for future activities for the Barnstable Ponds. Data from 38 ponds were identified, which generally focused on two sources: 1) individual pond studies with intensive year-long data collection; and 2) data collect through the Pond and Lake Stewardship (PALS) Snapshots conducted through the CCC and the SMAST between 2001 and 2007. The report concluded that available datasets for Barnstable's ponds were generally insufficient for drawing conclusions regarding the sources of nutrients and other factors affecting water quality and habitat conditions in individual ponds, but were sufficient for comparing conditions among ponds.

Lake Wequaquet Water Quality Assessment draft FINAL REPORT October, 2008 for the Town of Barnstable and Cape Cod Commission (SMAST, 2008). The Town of Barnstable contracted with the Coastal Systems Program, School of Marine Science and Technology (SMAST), University of Massachusetts Dartmouth through the Cape Cod Commission (CCC) to update the analysis of water quality conditions in Lake Wequaquet and connecting waterways. Sampling was conducted in summer 2007. This report documents the sampling results and their interpretation, as well as an evaluation of the relationship of the lake to its watershed through water, nitrogen, and phosphorus budgets.

Cape Cod Pond and Lake Atlas, Final Report (CCC Water Resources Office, 2003). The Cape Cod Commission Water Resources Office published the Cape Cod Pond and Lake Atlas in May 2003; this document presents a summary and analysis of water quality status of twelve of the Barnstable ponds. The summaries provide an overview, indicating location, the nature of the shoreline, and predominant land uses. The fish community and stocking activities are described. Results of an August 2001 sampling program are tabulated for 35 ponds; chlorophyll-*a*, phosphorus and nitrogen concentrations are compared with thresholds for impaired ponds.

4.2 Visual field assessment

In July 2009, EcoLogic LLC conducted a field visit of 20 of the Barnstable ponds to observe water clarity and color, shoreline vegetation and development, public access and recreational uses, and the presence of algae and macrophytes.

4.3 Delineation of contributing areas

The Town of Barnstable GIS Unit developed a draft map delineating the recharge areas and land use in the Town. Information on this map included acreage of the recharge areas, number of parcels, existing residential units, and existing commercial building square footage. A build-out analysis was conducted to estimate the total extent of development possible under existing zoning regulations.

5 Inventory of ponds

The Barnstable ponds exhibit a range of physical characteristics (**Table 2**). Additional details are presented in Appendix A.

Table 2. Physical Characteristics of the Barnstable Ponds

5.1 Current Water Quality and Habitat Conditions

Ponds deeper than about 5 m typically exhibit some degree of thermal stratification during the summer. Bottom waters isolated from the atmosphere become depleted of oxygen (i.e., develop anoxia) as the microbial community decomposes organic material that settles to the lake bottom. As ponds become more productive, oxygen depletion is evident higher in the water column.

The shallowest ponds do not develop stable thermal stratification, because the winds are able to keep the water column mixed from top to bottom. As a consequence, oxygen added to the pond from the atmosphere and from photosynthesis mixes throughout the water column and the waters remain oxygenated.

Eagle Pond

Ponds deep enough to stratify and productive enough to experience seasonal anoxia have elevated concentrations of phosphorus in the lower waters, due to the chemical changes at the sediment surface that occur during anoxia. As a result of these chemical changes, phosphorus is released from sediments to the overlying waters. In some lakes, wind-induced mixing and internal waves (seiches) may draw the phosphorus-rich water into the upper sunlit layer where the nutrient can support algal growth (the photic zone) during the summer. Several of the shallower ponds are susceptible to the effects of internal phosphorus loading during summer. As waters cool in the fall, the density gradients that prevented wind mixing break down and the phosphorus-rich layer is mixed into the water column of all ponds, regardless of depth.

Limnologists have developed guidelines to delineate the transition between trophic states based on phosphorus, water clarity, chlorophyll-a, and deep water dissolved oxygen concentrations (**Table 3**). However, assigning a lake or pond to one category still requires professional judgment considering the cumulative evidence of water quality conditions and the level of productivity (**Table 4**).

July 2009

Table 3. Trophic State and Indicator Parameters

Trophic State	TSI Values	Attributes and Recreational Use	*TSI Calculation* *TSI(TP) = 14.42 ln(TP) + 4.15* Total Phosphorus	*TSI(CHL) = 9.81 ln(CHL) + 30.6* Chlorophyll-a	*TSI(SD) = 60 – 14.41 ln(SD)* Secchi disk transparency
Oligotrophic	<30-40	Clear water, oxygen throughout the year in the hypolimnion. At TSI >30, hypolimnia of shallower lakes may become anoxic. Salmonid fisheries.	<6 to 12 µg/l	<0.95 to 2.6 µg/l	>8 to 4 m
Mesotrophic	40-50	Water moderately clear; increasing probability of hypolimnetic anoxia during summer. Hypolimnetic anoxia results in loss of salmonids.	12 to 24 µg/l	2.6 to 7.3 µg/l	4 to 2 m
Eutrophic	50-70	Anoxic hypolimnia, macrophyte problems possible. At TSI >60, blue-green algae dominate, algal scums and macrophyte problems. Warm-water fisheries only. Bass may dominate. At TSI >60, nuisance macrophytes, algal scum, and low transparency may discourage swimming and boating.	24 to 96 µg/l	7.3 to 56 µg/l	2 to 0.5 m
Hypereutrophic	>70	Light limited productivity. Dense algae and macrophytes. Rough fish dominate; summer fish kills possible.	96 to 384 µg/l	56 to >155 µg/l	0.5 to <0.25 m

after Carlson and Simpson (1996); Carlson TSI developed in algal dominated, northern temperate lakes

Table 4. Summary of Trophic State Parameters, Barnstable Ponds

Trophic State	Depth Class		
	Ultra-Shallow	**Shallow**	**Deep**
Oligotrophic	Hathaway (South) Mary Dunn Mill (MM) Red Lily	Garrett's Joshua	Hamblin Hathaway (North) Micah Middle Neck Shubael
Mesotrophic	Aunt Betty's Bog Fawcett Lumbert	Bearse Coleman No Bottom Shallow	Crystal Lovell's Mystic Wequaquet
Eutrophic	Dunn's Little/Stony Mill (WB)	Eagle Elizabeth Hinckley Long (C'ville) Long (MM) Muddy Parker Round (MM)	
Hypereutrophic	Little Parker	Schoolhouse	

based on Eichner, 2008

The visual assessment conducted by EcoLogic in July 2009 confirmed that the Barnstable Ponds are in various stages of eutrophication.

While data are limited, they do provide a basis for making an assessment of trophic state using the standard indicators described in **Table 3**. Note that the concentrations of chlorophyll-a and phosphorus used to delineate trophic state (**Table 3**) are not the same as the concentrations used to define ecoregional reference lake conditions (**Table 5**). The ecoregional criteria are based on water quality conditions measured in eight pristine Cape Cod ponds.

Table 5. Ecoregional Criteria

Parameter	**Subecoregion 84 Reference Condition Threshold**	**Cape Cod Ponds based on 2001 PALS Data**
Secchi depth	2 m	Not calculated
Chlorophyll-a	6 µg/l	1.7 µg/l
Total Nitrogen	0.41 mg/l	0.31 mg/l
Total Phosphorus	9 µg/l	10 µg/l

EPA is encouraging development of ecoregional criteria, designed to reflect site-specific conditions of watershed geology, land use, and hydrologic setting. These values are used to define thresholds for impacted and non-impacted conditions and thus target levels. Ecoregional

criteria for Cape Cod ponds have been described in the Cape Cod Pond and Lake Atlas (Cape Cod Commission, May 2003); the ecoregional values (designated as subregion 84) are derived from a statistical evaluation of existing water quality conditions of "unimpacted" ponds for coastal New England, including Cape Cod. The 2001 PALS data were used to calculate thresholds for reference conditions using eight Cape Cod ponds. The eight ponds included a range of deep and shallow ponds; all were characterized with low nutrient and chlorophyll concentrations. One of these eight reference ponds was Barnstable's Micah Pond.

The status of the Barnstable Ponds with respect to the ecoregional criteria is summarized in **Table 6**, based on the data summaries provided by Eichner (2008).

Table 6. Status of Barnstable Ponds, based on Cape Cod Ponds Thresholds.

Pond	Impacted Criteria (Affected by Human Activities)		
	Chlorophyll-a >1.7 µg/l	Total N > 0.31 mg/l	Total P > 10 µg/l

Wequaquet	Impacted	Impacted	Impacted

In addition to grouping the ponds based on the degree to which human activities have altered them from their natural (pristine) condition, each state classifies surface waters for a desired "best use". This concept focuses on human use of the resource, but incorporates the ecological condition of the resource as well. Examples of designated use include public water supply, fishing, swimming (water contact recreation), aesthetic enjoyment and support of shellfish, wildlife and fisheries. The best use of Barnstable's inland kettle ponds is typically recreation in and on the water and fishing. It is important to note that the designation of a pond as showing evidence of impact by humans (i.e., "impacted" or "at risk") does not imply that the pond's designated uses are not being supported. Overall, the town's inland ponds fully support their designated use.

Based on this analysis, the Barnstable Ponds may be grouped into categories describing current water quality and habitat conditions. This grouping is presented in **Table 7.**

Table 7. Summary of Current Water Quality Conditions and Use Attainment.

Depth Categories:	Water Quality and Aquatic Habitat Status		
	Supports Desired Uses	**Currently Supports Desired Uses, with Evidence of Degradation**	**Does Not Support Desired Uses**
Ultra-shallow (less than 1.2 m maximum depth)	Aunt Betty's Hathaway (South) Lumbert Mary Dunn Mill (MM)	Red Lily Bog Dunn's Fawcett Little/Stony Mill (WB)	Little Parker
Shallow (from 2.1 to 8.6 m maximum depths)	Garrett's Joshua Eagle	Bearse Coleman Long(MM) Elizabeth No Bottom Round (MM) Shallow	Hinckley Long (C'ville) Muddy Parker Schoolhouse
Deep (from 9.3 to 17.3 m maximum depths)	Hathaway (North) Micah Middle Neck	Chrystal Hamblin Mystic Shubael Wequaquet	Lovell's

The nitrogen: phosphorus (N: P) ratio is another measure of pond conditions. Algae require many nutrients, and their nutritional requirements are within a relatively consistent range. As a general rule, higher N:P ratios are associated with lower productivity. When the elemental N:P ratio in the water column falls below about 16, nitrogen becomes the limiting nutrient for algal growth. Many species of cyanobacteria are able to fix atmospheric nitrogen (i.e., convert nitrogen gas (N_2) to ammonia and other more readily useable forms of nitrogen). As a consequence, growth of these species is not limited by the availability of nitrogen in the water, and cyanobacterial abundance can reach nuisance levels in eutrophic lakes.

The N:P ratio of the Barnstable ponds (**Table 8)** tends to be high. The N:P ratio, on average, decreases from more than 100 for the less productive ponds to less than 10 for the most nutrient-rich and productive ponds. Lovell's Pond, which was closed for swimming in July 2009 due to a cyanobacterial bloom, exhibited a relatively low N: P ratio of 25:1 in 2001.

Table 8. Nitrogen:Phosphorus Ratios, Barnstable Freshwater Ponds, 2001

Ultra-Shallow		Shallow		Deep	
Oligotrophic (>100)		*Oligotrophic (>100)*		*Oligotrophic (>100)*	
Red Lily (Lower)	179:1	Long (August)	112:1		
Mid-Range (<100 and >10)		*Mid-Range (<100 and >10)*		*Mid-Range (<100 and >10)*	
Aunt Betty's	29:1	Bearse	19:1	Crystal	52:1
Bog	26:1	Coleman	25:1	Hathaway North	65:1

Little	51:1	Long (Sept.)	31:1	Middle	46:1
Mary Dunn	33:1	Muddy	22:1	Mystic	23:1
		Parker	72:1	Shubael	73:1
		Round	45:1	Wequaquet Middle	22:1
		Shallow	32:1		
Eutrophic (<10)		*Eutrophic (<10)*		*Eutrophic (<10)*	
Dunns	9:1	Schoolhouse	8:1		

Based on data from Cape Cod Pond and Lake Atlas, May 2003.

5.2 Data Gaps

The evaluation of the data in Eichner (2008) repeatedly emphasized that only limited data were available to analyze the status and trends of the Barnstable ponds.

> *"When looking at all of this data, there are two significant factors that must also be considered: all of these characterizations are based on very limited data and there are a number of Barnstable ponds that do not have any data. Except for Mystic, Middle, and Hamblin, the rest of the ponds have not had water quality samples collected since 1986 except for PALS Snapshots. The PALS Snapshot data is useful for what it was designed for, a Cape-wide picture of pond water quality, but it is not sufficient for definitively stating the status of individual ponds or designing remedial strategies." (Eichner, 2008)*

5.3 Land Use and Phosphorus Sources

Phosphorus can reach the inland kettle ponds from several sources. Runoff from impervious surfaces, such as roadways, can transport dissolved and particulate material, including phosphorus, to the ponds. Eroding shorelines can contribute particulate material as well. Groundwater seepage transports dissolved nutrients into ponds; the concentrations of dissolved nutrients can be elevated when groundwater is affected by sewage disposal. There are biological sources as well, including waterfowl and humans.

Maps of current land use, depicting the number and location of residences, were reviewed during preparation of this Action Plan for Barnstable. This coverage area of impervious surfaces is important to consider in quantifying phosphorus loading to the ponds from the surrounding watershed due to surface runoff. The density of development is a factor in phosphorus loading from septic systems.

Mill Pond – Conservation Area visitor location map.

Review of the map of government-owned land and protected open space (Town of Barnstable, 2009) indicates that the majority of parcels within the town are in private ownership and not under conservation protection. However, many of the smaller ponds have a substantial portion of the watershed in town-owned or conservation lands.

Most of the town is not served by sanitary sewers. Therefore, septic effluent is likely a contributing factor in phosphorus loading to most of the Barnstable ponds. Once the contributing area of groundwater flow into each pond is delineated, these data can be used to help quantify the potential contribution of septic effluent to each pond.

Parcels in the Town of Barnstable that have sewer accounts have been mapped. According to a map[1] dated October 2007, these parcels are predominantly located on the eastern side of town, east of the Lake Wequaquet region. One would anticipate that parcels with sewer accounts would have fewer active septic systems, and that septic contributions of phosphorus to the ponds adjacent to these parcels would be reduced. Ponds in this region include:

Aunt Betty's	Fawcett's	Lewis
Crooked	Fresh	Mary Dunn
Duck	Fresh Hole	Upper Gate
Dunn's	Hathaway (South)	

5.4 Build-out Analysis

Changes in land use over time will have an impact on the Barnstable ponds. To estimate the amount of development possible in the town, and thereby identify ponds likely to be most affected, a build-out analysis was conducted. The analysis grouped 29 ponds into 17 areas around Barnstable, and tallied the existing and build-out quantities for residential dwelling units and commercial building square footage (**Table 9**).

[1] http://www.town.barnstable.ma.us/InformationSystems/GIS/SEWERED.PDF

Table 9. Build-out Analysis of Residential Dwelling Units and Commercial Building Square Footage, Town of Barnstable.

Pond(s)	Residential Dwelling Units			Commercial Bldg Sq Footage		
	Existing	Build-out	Change	Existing	Build-out	Change
Lovell	245	353	+108	0	0	0
Muddy, Long (MM)	138	143	+5	0	0	0
Eagle	60	61	+1	0	0	0

[Number 15 on map]	0	0	0	43,192	180,657	+137,465
Mary Dunn	0	0	0	1,410	1,410	0
Israel, Lamson	0	0	0	119,114	464,441	+345,327

from draft GIS map "Town of Barnstable Freshwater Ponds Recharge Areas", August 2009

Ponds that have potential for extensive future residential development, based on this build-out analysis, are:

Lovell	Mystic-Middle-Hamblin-Shubael-Little
Fawcett	Wequaquet-Bearse-Shallow-Long (C'ville)
Garrett's	Hathaway[2]

Other ponds exhibiting potential for extensive future commercial development, based on this build-out analysis, include:

[2] The lands around Hathaway Pond (both North and South) are predominantly owned by the Town and designated for conservation and recreation; therefore, the projected increase in development is unlikely.

Israel-Lamson	Wequaquet-Bearse-Shallow-Long (C'ville)
"Number 15"	Fawcett's
Simmons-Ben	

Given this assessment of potential for development, ponds which presently do not meet desired uses, and ponds with evidence of degradation are considered most at risk (**Table 10**).

Table 10. Water Quality Conditions of Ponds with Potential for Extensive Future Development.

	Water Quality and Aquatic Habitat Status		
Development	**Meets Desired Uses**	**Meets Desired Uses, with Evidence of Degradation**	**Does Not Meet Desired Uses**
Residential	Garrett's Middle	Bearse Fawcett Hamblin Little Mystic Shallow Shubael Wequaquet	Long (C'ville) Lovell's
Commercial		Bearse Fawcett Shallow Wequaquet	Long (C'ville)

Note: there were no data to categorize the water quality conditions of Israel, Lamson, "Number 15", Simmons or Ben.

5.5 Point and nonpoint sources of nutrients

There are no identified point sources of nutrients to the Barnstable Ponds; most of the nonpoint sources are direct inputs to the ponds: septic effluent, wildlife, swimmers, stormwater runoff, and shoreline erosion.

Septic effluent as a nonpoint source is the subject of investigation and debate. The extent to which phosphorus in septic effluent can reach surface waters is an issue of great importance to many communities. Research and monitoring indicates that subsurface phosphorus transport is influenced by depth to groundwater, soil texture, pH, geology, and groundwater quality, as well as by the nature of the on-site wastewater disposal systems (notably age, loading history, and maintenance).

5.6 Transport and attenuation from source to ponds

In general, phosphorus is considered relatively immobile in the subsurface environment. However, phosphorus transport through groundwater to surface waters has been documented; for example, phosphorus associated with the sewage plume from the Massachusetts Military Reservation on Cape Cod is reaching Ashumet Pond (McCobb et al 2003). Phosphorus from septic systems may reach surface waters when intervening distances and travel times are short, when the groundwater environment is reducing (anoxic), or when sites for sorption of phosphorus onto aluminum and iron oxides are already saturated with phosphorus (Portnoy et al 2001). The Ashumet Pond investigation by USGS documented that phosphorus can desorb from subsurface soils exposed to uncontaminated groundwater with low pH (McCobb et al. 2003). This implies that phosphorus from on-site systems remains a reservoir in the soil that may be slowly mobilized and transported to the ponds along with groundwater.

Controlled experiments by Cogger et al (1988) examined the movement of nutrients and bacteria from septic systems installed in the sandy soils of a coastal barrier island. They reported that phosphorus was most likely to be mobile in wet, sandy soils, and that both loading rate and water table location affected phosphorus concentrations in the groundwater surrounding the leach field. Data from this investigation were also consistent with two processes for adsorption occurring: a fast reaction and a slow reaction.

The ponds of Barnstable are situated in sandy soils, and the surrounding land areas have a variable depth to groundwater. Background pH is low, averaging 5.5 (McCobb et al. 2003). The sandy soils provide abundant iron and aluminum hydroxides for phosphorus adsorption. The reaction of soluble reactive phosphorus with sandy soil is described by two processes: a fast and reversible adsorption reaction on the surface of aluminum and iron oxides and a slow, diffusion-controlled process where the phosphorus either precipitates with aluminum or iron, or diffuses into micropores and becomes adsorbed to surfaces deep in the soil matrix (Shoumans and Breeuwsma 1997).

It appears that the soils of Barnstable have the cation exchange capacity and mineralogy to adsorb soluble phosphorus present in groundwater. However, phosphorus removal is not permanent. Under certain chemical conditions, phosphorus adsorbed to the surface aluminum and iron hydroxides may desorb and move with the groundwater towards the kettle ponds. Groundwater pH on Cape Cod is within the range where this desorption reaction will occur. Phosphorus movement from subsurface soils would be exacerbated by conditions such as high organic loading that contribute to microbial activity and de-oxygenation of the groundwater resource.

6 Summary of Findings

- **Water Quality Conclusions (Eichner, 2008).** The focus of the conclusions was centered on total phosphorus, chlorophyll-a, and dissolved oxygen as key data sets indicating pond health. In all cases, further data collection was recommended to refine the characterization of each pond. *Overall recommendation*: Standard best management practices to minimize stormwater runoff would help maintain/improve existing conditions.

    a. Ultra-shallow Ponds – Total phosphorus and chlorophyll-a concentrations were generally higher than threshold concentrations, while dissolved oxygen was compliant with the regulatory standards. Hathaway South and Mary Dunn Ponds are relatively pristine and undeveloped, and should be a priority for protection.

    b. Shallow Ponds – Total phosphorus and/or chlorophyll-a concentrations were excessively higher than threshold concentrations, while six of the 15 ponds exhibited dissolved oxygen concentrations in the deeper waters that were below the regulatory standards. Joshua was identified as a relatively pristine pond that should be protected.

    c. Deep Ponds - Total phosphorus and/or chlorophyll-a concentrations were higher than threshold concentrations, while eight of the 10 ponds exhibited dissolved oxygen concentrations in the deeper waters that were below the regulatory standard. None of the ponds may be considered relatively pristine, but several have only recently shown signs of water quality impairment: Micah, Middle and Neck. The alum treatment of Hamblin Pond continues to provide residual water quality benefits.

- **Impacted Waters.** The Barnstable Ponds are in various stages of eutrophication; many are considered "impacted waters" based on regional criteria developed from limited measurements of water quality conditions in eight pristine Cape Cod ponds. However, designated uses are generally met. The ponds are used for swimming, boating, recreational fishing and aesthetic enjoyment. While a few ponds exhibit visual degradation of water quality conditions, most are aesthetic assets and provide habitat for a diverse assemblage of aquatic plants and animals.

- **Phosphorus Loading.** Phosphorus is the limiting nutrient for primary production in the Barnstable Ponds, and therefore has an influence on water quality conditions and pond health.

    a. Unlike the nitrogen-limited coastal embayments, production of algae and macrophytes in inland ponds is limited by phosphorus. The ratio of nitrogen to

phosphorus in ponds is likely to influence the species composition of the algal community, particularly the importance of blue-green algae.

b. Phosphorus enters the Barnstable Ponds from several sources; few (if any) of these sources are easily controlled. External sources of phosphorus include: groundwater influx; wastewater disposal (septic sewage plumes in groundwater); surface runoff; atmospheric deposition; shoreline erosion; and users of the ponds (swimmers and wildlife).

c. In deeper ponds subject to seasonal anoxia, phosphorus held in sediments can be released to the overlying waters; this internal loading can be a significant fraction of the annual supply of phosphorus available to support algal growth.

d. Kettle ponds are susceptible to phosphorus accumulation, due in part to the lack of surface outlets.

e. The watershed area of many of the Barnstable ponds includes parcels with on-site wastewater disposal systems. Installation of sewers to collect domestic wastewater before it enters the groundwater would likely reduce phosphorus loading to these ponds.

f. Build-out analysis was used to identify ponds where there is a high potential for future residential and commercial development. Such future development could increase phosphorus loading from surface runoff and groundwater seepage of sewage plumes.

7 Recommendations

Given the nature of the kettle ponds and the sources of phosphorus to the Barnstable Ponds, there are no simple answers to long-term water quality protection and improvement. Strategies fall into several categories: reducing the inputs of nutrients and sediment, altering internal cycling, increasing the output of nutrients and sediment, and/or mitigating the symptoms of eutrophication. Feasible alternatives for protection and restoration of the Barnstable Ponds are summarized in **Appendix B**. The following actions are recommended.

- **Develop town-wide strategies for water quality protection.**

  Some of these strategies would be implemented through Town Codes and regulation, while other strategies could be implemented without regulatory involvement. Storm water runoff controls would be one example of a regulatory action. Public education would be an example where regulatory involvement is not required.

- **Develop pond-specific strategies to protect and/or restore individual Barnstable Ponds.**

  Each pond has its own unique situation, based on its size and depth, the nature of the surrounding watershed, and the extent of groundwater influences. With a more detailed understanding of the individual pond through additional data collection, it will become more apparent whether actions such as alum treatment or weed harvesting are appropriate in a given pond.

- **Obtain more detailed data on priority ponds.**

  As noted above, there are very limited recent data to characterize water quality and habitat conditions of the town's ponds Additional data collection should be prioritized to ponds that are the most impaired, and that provide the greatest opportunity for public uses. Moreover, data collection should be focused on closing data gaps needed to make effective management decisions.

7.1 Priority Ponds

An assessment of the priority status of the Barnstable Ponds **(Table 11) includes** Barnstable inland ponds reviewed as part of this assignment; the list is not inclusive of all town ponds.

Table 11. Summary of existing conditions, recommended actions, and priorities for managing Barnstable Ponds

Pond	Priority (low-moderate-high-protect)	Findings (Trophic States: O, M, E, H)	Recommended Actions
Ultra-Shallow			
Aunt Betty's	Low	M; Limited public access	Education, watershed BMP
Bog	Low	M; Impacted/at risk	Education, watershed BMP
Dunn's	Moderate	E; Impacted	Education, watershed BMP
Fawcett's	Low	M; Impacted/at risk; potential for increased residential development	Education, watershed BMP; guide future development to minimize nutrient export
Hathaway (South)	Protect	O; Unimpacted	Low impact recreational use & education in protected watershed
Little Parker	High	H; Impacted; does not support desired uses	Watershed BMPs; mitigate symptoms to improve aesthetics and recreational use: hand-pulling, benthic barriers
Little/Stony	Moderate	E; Impacted/at risk	Education, watershed BMP
Lumbert	Low	M; Private; Impacted/at risk	Education, watershed BMP
Mary Dunn	Low	O; Impacted/at risk	Education, watershed BMP
Mill(MM)	Protect	O; Impacted; Conservation area	Low impact recreational use & education in protected watershed
Mill (WB)	Moderate	E; Impacted	Education, watershed BMP
Red Lily (North, South)	Low	O; Impacted/at risk; Limited public access	Education, watershed BMP
Shallow			
Bearse	Moderate	M; Impacted/at risk; fanwort; potential for increased residential development	Macrophyte survey, strategies to control exotics; consider reducing density of future development

Pond	Priority (low-moderate-high-protect)	Findings (Trophic States: O, M, E, H)	Recommended Actions
Coleman	Low	M; Impacted	Mitigate symptoms of eutrophication in recreational areas (benthic mats, hand harvesting); watershed BMPs
Eagle	Protect	E; At risk; watershed in land trust	Consider hand pulling emergent vegetation to improve shoreline access; maintain trails and prevent erosion
Elizabeth	Moderate	E; Impacted; Limited public access	BMPs, control stormwater on roadways
Garrett's	Low	O; At risk; limited public access	Education, watershed BMPs
Hinckley	High	E; Impacted	Stormwater management, septic inspections
Joshua	High	O; At risk; Town beach, natural vegetation; reference pond indicative of pristine conditions	Priority for protection, education, BMPs
Long (C'Ville)	High	E; Impacted; Town beach, highly developed; Does not support desired uses	Stormwater management, septic inspections, mitigating measures to improve recreational use: benthic mats, hand-pulling
Long (MM)	Moderate	E; Impacted; Conservation area; moderately protected	Education, watershed BMPs
Muddy	Moderate	E; Impacted/at risk	Education, watershed BMPs
No Bottom	Low	M; Impacted	Education, watershed BMPs
Parker	Moderate	E; Impacted	Education, watershed BMPs
Round (MM)	Moderate	E; Impacted/at risk; Private	Education, watershed BMPs
Schoolhouse	High	H; Impacted; does not support desired uses	

Pond	Priority (low-moderate-high-protect)	Findings (Trophic States: O, M, E, H)	Recommended Actions
Shallow	Moderate	M; Impacted/at risk; vegetated shoreline; potential for increased residential development	Controls on future density and/or BMPs to minimize phosphorus migration to pond from surface runoff and groundwater
Deep			
Crystal	Low	M; Impacted	Education, watershed BMPs
Hamblin	High	O; At risk; Town Beach, conservation land; alum-treated; potential for increased residential development	Monitor for effectiveness of alum treatment; controls on future density and/or BMPs to minimize phosphorus migration to pond from surface runoff and groundwater
Hathaway (North)	High	O; At risk; Town beach, mix of conservation land and development	Continue acquisition of hydrologically important parcels in watershed
Lovell's	High	M; Impacted; Town beach closed; blue-green algal bloom; does not support desired uses	Priority for monitoring deep water phosphorus levels and N/P ratio; consider nutrient inactivation
Micah	Protect	O; At risk; Undeveloped, reference pond	Priority for monitoring deep water phosphorus levels
Middle	Protect	O; At risk; Public access, very clear	Priority for monitoring deep water phosphorus levels; consider acquisition of key parcels to control density
Mystic	High	M; Impacted/at risk; Public access, endangered mussels; permit phase for alum application; potential for increased residential development	Priority for alum treatment program; guide future development to minimize surface runoff and groundwater nutrient input

Pond	Priority (low-moderate-high-protect)	Findings (Trophic States: O, M, E, H)	Recommended Actions
Neck	Moderate	O; Impacted/at risk;	Period monitoring to detect symptoms of degradation; watershed BMPs;
Shubael	High	O; Impacted; Town beach, exceptionally clear water potential for increased residential development	Priority for monitoring deep water phosphorus levels; septic inspections; guide future development to minimize nutrient input from surface runoff and groundwater seepage
Wequaquet	High	M; Impacted; Town beach, potential for future residential and commercial growth	Priority for monitoring deep water phosphorus levels; septic inspection; consider density controls on future development

Trophic states: O – Oligotrophic; M – Mesotrophic; E – Eutrophic; H -Hypereutrophic
Higher priority assigned to ponds with town beach and/or public access
BMP- Best Management Practices

7.2 Protection Measures

The following are measures that may be taken to protect the Barnstable Ponds from further degradation in water quality and habitat conditions. These measures are typically implemented in the watershed surrounding the ponds, rather than within the pond itself. These protection measures may be applied to all the ponds, though more information regarding existing storm water infrastructure could help the town refine priorities.

- Storm water management. Stormwater basins with water quality controls; operations and maintenance are critical. Improved stormwater management on parking lots adjacent to ponds.

- Septic discharge. Regulatory programs for septic systems existing in similar environments to the Cape Cod area show a variety of setback requirements, as summarized in **Appendix C**. In addition to setbacks, there are alternative technologies, some of which show excellent phosphorus removal capabilities. The Massachusetts Alternative Septic Systems Test Center and the Barnstable County Department of Health are an informational resource. For a listing of current MADEP approved alternative systems, refer to the web site http://www.mass.gov/dep/water/wastewater/techsum.htm

- Public Education. Conduct forums to discuss pond ecology, range of conditions in Town ponds, and effective measure for improving water quality conditions. Educate the public regarding the importance of remaining on trails and protecting riparian (shoreline) areas. Also, educate land owners about the impacts of fertilizer and pesticide applications adjacent to ponds.

- Land acquisition. Pursue and acquire open space, while incorporating resource-based priorities into decisions. Place a high priority for acquisition of properties in riparian areas.

- Bioengineering. Revegetate shoreline areas to reduce shoreline erosion. Plan, install and maintain trails through public lands to reduce potential for erosion.

- Other structural measures. Implement wastewater collection to reduce phosphorus loading via septic systems. Install public toilet facilities for beach areas, and keep them cleaned and maintained to encourage use.

- Inspection and Monitoring. Inspection and maintenance of onsite septic systems. Routine participation in volunteer (PALS) water quality monitoring program. Additional monitoring suggestions are summarized in **Appendix D**.

7.3 Restoration Options

The following are measures that may be taken to restore the impacted Barnstable Ponds. These measures would be implemented as needed on a pond-by-pond basis. Additional data from the impacted ponds is required before selecting an appropriate restoration option.

- Alum treatment to seal bottom sediments. Alum application to seal bottom sediments and prevent phosphorus release. This treatment option is applicable to deep ponds that develop stable thermal stratification, and where internal (sediment) phosphorus release is a significant component of the annual TP budget.

- Mixing. Use aerators or mixers to keep the water column oxygenated and accelerate the rate of decomposition of organic material.

- Benthic barriers. To prevent the excessive growth of vegetation, a symptom of eutrophication. This technique may be applicable to limited areas to restore recreational use.

- Mechanical or hand removal of weeds. To eliminate invasive species and reduce the excessive growth of aquatic plants that impairs desired uses of the pond.

- Water level management (drawdown) to control aquatic plants.

8 Priority Actions Recommended for the Town of Barnstable for 2010-2011

Convene a public educational forum to discuss current water quality and habitat conditions of the ponds of Barnstable. Solicit public input on the desired future for the ponds (overall and for individual ponds). Major topics include:

- The eutrophication process
- The unique nature of the kettle ponds in nutrient cycling
- How conditions have changed in recent decades
- Alternatives for protection and restoration
- Why each pond requires a different strategy (no action, protection, active intervention) based on its physical characteristics, current conditions, and desired use
- The costs and benefits associated with alternatives
- How overall wastewater and facilities decisions may affect the ponds

Initiate a focused monitoring program to evaluate use attainment, confirm priorities for intervention, and assess the effectiveness of control measures.

The recommended monitoring plan is included as Appendix D.

Prepare an annual Pond Report Card to enhance public understanding of water quality conditions and contributing factors.

Consider a local law requiring periodic inspection and pump out of individual on-site wastewater treatment systems. The frequency can be linked to distance to ponds, with more stringent requirements within a defined buffer zone.

Review local erosion and sedimentation control laws and determine if they could be improved to prevent sediment loss to the ponds. If warranted, propose revisions for approval.

Convene technical committee (or engage a consultant) to initiate detailed planning and cost estimating, identify funding sources, secure non-local funding as available, and acquire permits for alum application to ponds as identified by the Town based on new data.

Appendix A. Summary of Physical Characteristics: Barnstable Ponds

Pond	Surface Area (acres)	Delineated Watershed[1] (Y/N)	Physical Characteristics[2]				
			Access/ Use[3]	Water clarity and color	Shoreline	Macrophytes	Comments
Ultra-shallow Ponds - depths between 0.5 and 1.2 m							
Aunt Bettys	7.1	N	VL		Buildings encroach, most of shoreline remains undisturbed	Submerged and yellow lilies	Very limited public access and recreational use
Fawcetts	11.9	Y	na	na	na	na	na
Lumbert	9.7	Y	Pv	Brown-tannin	Fully vegetated (from vantage point of survey)	More surface growth	Roadway pulloff Private
Mary Dunn	18	Y	na	na	na	na	na
Mill (Marston Mills)	6.0	N		Clear	Natural	Emergents	Roadway historical marker; impoundment. Conservation area.
Mill (West Barnstable)	16.7	N	na	na	na	na	na
Red Lily	4.5	N	VL		Vegetation mostly intact; few large homes	Extensive lilies	Connected to Elizabeth (to the south)

Appendix A. Summary of Physical Characteristics: Barnstable Ponds

Pond	Surface Area (acres)	Delineated Watershed[1] (Y/N)	Physical Characteristics[2]				
			Access/ Use[3]	Water clarity and color	Shoreline	Macrophytes	Comments
Shallow Ponds: depths between 2.1 and 8.6 m							
Bearse	66.8	Y	Pm (2003)	2.3m Secchi (2003)	Residential development (2003)	Treated to limit growth of fanwort (2003)	Connected to Wequaquet High TP and chlorophyll suggest productive algal population (2003)
Eagle	8.5	Y	CA	Clear	Intact. Undeveloped	Pink water lilies, black benthic mat	Walking trails, full-land trust (Mary Barton Land Trust) "relatively clean, largely unimpacted lake" (2003)
Elizabeth	6.3	N	VL			Extensive lilies	Connected to Red Lily (to the north)
Garretts	27.9	N	Pm	Tannins	Some development, few cleared lawns	Yellow lilies	"relatively clean lake with uncertain deep water quality concerns" (2003)
Hinckley	10.3	N	na	na	na	na	na
Joshua	14.7	Y	TB	Clear water; brown benthic layer	Completely natural vegetation		town beach and bath house "relatively clean, largely unimpacted lake" (2003)

Appendix A. Summary of Physical Characteristics: Barnstable Ponds

Pond	Surface Area (acres)	Delineated Watershed[1] (Y/N)	Physical Characteristics[2]				
			Access/ Use[3]	Water clarity and color	Shoreline	Macrophytes	Comments
Shallow Ponds: (continued)							
Long (Centerville)	51.0	Y	WTW; Limited	Clear	Highly developed, lots of clearing	Not evident (Sonar treatment)	Hydrilla, restricted access to reduce spread of this invasive Town Beach (2003) "impacted with water quality problems" (2003)
Long (Marstons Mills)	54.8	Y	CA	Clear	Mostly intact, some developed shoreline. Moderately protected	None evident	LI conservation area "impacted with water quality concerns" (2003)
Muddy	24.6	Y	None	--	--	--	Sand pile along shoreline
Parker	10.9	Y	na	na	na	na	na
Round (Marston Mills)	9.8	N	WTW	Clear	Vegetation present	Benthic algal mat, emergents (cattails)	Private. Good setbacks in riparian zone.
Shallow	78.4	Y	na	Clear	Shoreline mostly vegetated. Developed	Sandy bottom	Benthic detrital/ algal mat

Appendix A. Summary of Physical Characteristics: Barnstable Ponds

Pond	Surface Area (acres)	Delineated Watershed[1] (Y/N)	Physical Characteristics[2]				
			Access/ Use[3]	Water clarity and color	Shoreline	Macrophytes	Comments
Deep Ponds: depths between 9.3 and 17.3 m							
Crystal	10.1	N	na	na	na	na	na
Hamblin (Indian Ponds)	115.4	Y	Yes	Very clear	Mostly intact, some cleared lawns. (2009) Beach conservation land (2003)	Emergent (fringe) Cranberry bog (2003)	Bath house, swimming, kayak access. 1995 alum treatment; 10hp motor limit. (2009) "clearly impacted" (2003)
Hathaway (North)	20.9	N	TB	Very clear	Extensive, overhanging vegetation. Development surrounds pond. (2009) Town-owned conservation land (2003)	sandy bottom; some benthic macroalgae	Town beach, bath house, swimming area. Stocked with fish (smallmouth and largemouth bass, perch, pickerel, and sunfish). (2009) "relatively clean, largely unimpacted lake" (2003)
Lovells	55.5	Y	TB	Evidence blue-green algal bloom	Mostly intact; some cleared lawns	Sandy bottom, little vegetation visible	Town beach (closed on 7/30/09 due to algal bloom) and bath house; "impacted with water quality concerns" (2003)

Appendix A. Summary of Physical Characteristics: Barnstable Ponds

Pond	Surface Area (acres)	Delineated Watershed[1] (Y/N)	Physical Characteristics[2]				
			Access/ Use[3]	Water clarity and color	Shoreline	Macrophytes	Comments
Deep Ponds: (continued)							
Micah	16.0	Y	CA (2003)	--	Undeveloped public land (2003)	--	Selected as one of 8 reference ponds for Cape Cod during development of Cape Cod thresholds; "relatively clean, largely unimpacted" (2003)
Middle (Indian Ponds)	104.6	Y	Yes	Very clear		Minimal	Boating
Mystic (Indian Ponds)	148.4	Y	Yes	Clear	Mostly intact, more lawns than other ponds in the Indian Ponds group.	Pondweed	Public access, swimming and boating. Permit phase, alum. Endangered mussels.
Neck	13.6	N	na	na	na	na	na
Shubael	55.1	Y	TB	Exceptionally clear	Some Phragmites and cattails.	Sandy bottom, minimal benthic algal	Beaches, small boats. Horse farm (2009) Well-developed, stocked with fish; "impacted with water quality concerns" (2003)

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 1: Control Inputs from Watershed

	Option 1 – Wastewater Collection	Option 2 – Modifications to on-site wastewater disposal systems	Option 3 – Inspect/Maintain on-site wastewater disposal systems
Method	Reduce phosphorus from on-site wastewater disposal systems by centralized collection and disposal outside of watershed zone of influence	Various engineering alternatives to enhance removal of nitrogen, BOD, solids, and phosphorus (in various combinations) from domestic wastewater	Reduce phosphorus from on-site wastewater disposal systems by requiring frequent inspections and maintenance of systems
How does it work?	Collection system and treatment/disposal	Alternatives to conventional on-site wastewater disposal systems	Modification to local laws
Potential Benefits	Decreased loading of all wastewater contaminants, including pathogens	Decreased loading of nutrients and organic material to subsurface	Decreased loading of all wastewater contaminants, including pathogens
Potential Drawbacks	Could increase development pressure	More complex systems, more maintenance.	Public acceptance needs to be very high
Data gaps to make decision	Integrated with rest of wastewater decisions. Existing data do not define extent of problem	Existing data do not define extent of problem	Existing data do not define extent of problem
Costs (Relative)	High (likely to receive some public funds)	Moderate (may receive approval to install as a pilot system)	Low (borne by homeowners)
Permitting issues	Collection system will have environmental impact. Need to identify acceptable site for disposal to groundwater. Conservation Commission approval needed.	Massachusetts Alternative Septic System test center is in Sandwich, on Otis Air National Guard base. This is a cooperative program of the state, Barnstable County and SMAST	Dept. of Health & Conservation Commission approvals
Longevity	High	Moderate	Moderate
Ponds appropriate for this alternative	Ponds with high number of on-site systems. Insufficient data.	Impaired ponds with >20 residences. Non-impaired ponds, at least 15 residences. Based on water quality.	All ponds

*Source for cost estimates: *Holdren et al. 2001; **NYSFOLA, 2009*

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 1: Control Inputs from Watershed (continued)

	Option 4 – Infiltration Basins	Option 5 – Public Education	Option 6 – Wildlife Control
Method	Water quality inlets to stormwater infiltration basins	Public education and outreach	Discourage high populations of wildlife (especially gulls, geese) from spending long periods of time in ponds.
How does it work?	Stormwater collection and treatment prior to groundwater discharge	Educate public on importance of landscaping, erosion controls, beach sanitation	By using scare techniques to scare away birds, attain reduction of nutrient deposition from birds
Potential Benefits	Reduced loading	Reduced loading. Increase public awareness of ponds and their vulnerability	Reduced loading of nutrients and bacteria
Potential Drawbacks	Most systems designed to capture sediment. Higher maintenance	None	Scare tactics can be disruptive to human community.
Data gaps to make decision	No estimate of the contribution of soluble P from stormwater	None	Estimate maximum number of gulls, use research reported in Portnoy (1990)
Costs (Relative)	Low	Low	Low
Permitting issues	Requires siting, Conservation Commission approval needed.	None	Needs approvals from Fish and Wildlife, MADEP. Conservation Commission approval needed.
Longevity	Moderate	Moderate (prevention of incremental source likely to be a small source)	Likely to be effective only while active measures are taken, although birds may move to other areas
Ponds appropriate for this alternative	All, especially those with developed watersheds and evidence of sediment deposition from runoff. Insufficient data.	All	Insufficient data.

*Source for cost estimates: *Holdren et al. 2001; **NYSFOLA, 2009*

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 2: Alter Internal Cycling of Nutrients in Pond

	Option 1 – Alum Application	Option 2 – Sediment Oxidation	Option 3 - Circulation
Method	Alum application to remove phosphorus from water column	Sediment oxidation	Artificial circulation.
How does it work?	Alum hydrolyzes in water, forming a floc. As the floc settles it removes particulate material as well as any dissolved P. If applied properly, forms a barrier on sediment surface that continues to trap P.	Procedure injects calcium nitrate into top 10" sediment to break down organics and promote denitrification, and injecting ferric chloride to bind available phosphorus released from sediments.	Compressed air is injected into the lower waters. Eliminates thermal stratification. Oxygenates lower waters, more oxygen available to break down organic material.
Potential Benefits	Long history of use. Does not seem to affect other aquatic organisms. May create layer over sediments retarding future sediment P release. Long-term results. Readily available.	If successful will greatly reduce internal P loading from sediments	Reduces surface algal blooms, improved habitat for aquatic biota, may retard sediment P release
Potential Drawbacks	Low pH ponds, need buffering (sodium aluminate). Potential for aluminum toxicity if pH declines. Loss of benthic organisms.	Optimal pH of sediments 7 – 7.5; would require liming. Considered an experimental technique.	Results may be subtle. Requires energy source to power. May increase algal production throughout water column.
Data gaps to make decision	Sediment testing to estimate optimal dose	Sediment testing to calculate dose	DO profiles over growing season, history
Costs (Relative)	Can be high, application rate estimated at $70 per 40-lbs.(40 lbs. treats 1 acre-ft) * High initial cost - $100-$500 per acre.**	Can be high, $8,000 – $12,000 per acre *	Approximately $150/acre**. Variable, depending on power source. Solar-powered mixing devices: $25,000.
Permitting issues	Requires permit, testing for optimal dose. Conservation Commission approval needed.	Requires permit, testing for optimal dose. Conservation Commission approval needed.	Conservation Commission approval needed.
Longevity	Moderate (at least several years)	Moderate (at least several years)	Only effective when mixers working
Ponds appropriate for this alternative	Deeper ponds with elevated TP in lower waters. Insufficient data.	Impaired ponds with DO depletion. Insufficient data.	Insufficient data.

*Source for cost estimates: *Holdren et al. 2001; **NYSFOLA, 2009*

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 2: Alter Internal Cycling of Nutrients in Pond (continued)

	Option 4 - Dredging	Option 5 – Pond Drawdown
Method	Dredging	Drawdown of pond water level to expose sediments
How does it work?	Sediment is physically removed, also removing accumulated nutrients and organic material	Lowering water level will dry sediments and allow sediments to oxidize and compact.
Potential Benefits	Reduced internal nutrient supply, increases water depth, can reduce sediment oxygen demand	May alter nutrient availability for the better. Opportunity for shoreline cleanup. Nuisance plant species may die back.
Potential Drawbacks	Expensive if disposal site not nearby. Temporary turbidity, removes macroinvertebrates, temporarily interferes with recreation. Might reduce ponds' natural capacity for denitrification and thus allow more soluble nitrogen to make its way to coastal embayments.	Possible impacts on contiguous wetlands, may change habitat for amphibians. Desirable species of plants may die. Ponds with water level controls may be managed for herring. Temporary loss of waterfowl habitat. Potential to create highly unappealing aesthetic conditions for neighbors.
Data gaps to make decision	Quality of sediments affects disposal options and costs (e.g. hazardous waste). Detailed bathymetry required to estimate volumes and costs.	Water level control needed, therefore not feasible for most kettle ponds which lack such controls
Costs (Relative)	$15,000 - $50,000/acre*, depending on transportation needs to remove dredge spoils from site.	<$100/acre if structures adequate*
Permitting issues	Requires permit for dredging and disposal Conservation Commission approval needed.	Permit required, complexity depends on impacts on wetland and other ponds. Conservation Commission approval needed.
Longevity	Moderate to long-term	Moderate to long-term
Ponds appropriate for this alternative	Insufficient data.	Insufficient data.

*Sources for cost estimates: *Holdren et al. 2001; ** NYSFOLA, 2009*

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 3: Mitigate Symptoms of Eutrophication - Weeds and Algae

	Option 1 – Mechanical Harvesting of Weeds	Option 2 – Mechanical Weed Removal	Option 3 – Hand-Harvesting Weeds
Method	Mechanical harvesting of weeds	Mechanical removal of weeds, by rotovating (rototilling) or hydroraking.	Removal of plants by hand.
How does it work?	Upper part of plants cut in place, deeper waters; roots are not harvested. Cuttings collected and removed from pond.	Removes rooted aquatic plants from targeted areas by means of large cutters that dislodge roots and plants from sediment.	Removes rooted aquatic plants from targeted areas, using human labor.
Potential Benefits	Immediate results. Improved recreational access. Remaining lower part of plants continues to provide habitat.	More effective than mechanical harvesting, as the roots as well as plants are removed.	Effective rapid-response to invasive species. Selective plant management.
Potential Drawbacks	Non-selective, may alter plant communities, may remove native insects that help control plants.	Creates turbidity, disturbs the sediment, may spread some plants by fragmentation. Not selective; cuts all plants.	Labor intensive, restricted to small areas. May spread some plants by fragmentation.
Data gaps to make decision	Species and habitat affected, water depth. Equipment access, disposal.	Useful for shallower areas where recreational access is limited by weeds	Useful for small areas where recreational access is limited by weeds
Costs (Relative)	Leasing a harvester, $600-$2,400/acre**, depending on size of harvester.	Hydroraking or rotavation services $1,000** to $2,000* per acre	$100/acre* up to $1,000/acre**
Permitting issues	Minor, need to develop plan for harvesting and upland disposal sites. Conservation Commission approval needed.	Turbidity, avoidance of critical habitat areas and spawning/early life stages of fish community Conservation Commission approval needed.	Minimal; Conservation Commission approval needed.
Longevity	Two or more harvests during the recreational season.	Usually needs to be repeated several times year	Usually needs to be repeated once or twice a year
Ponds appropriate for this alternative	Insufficient data.	Insufficient data.	Areas where homeowners' access is diminishing. Insufficient data.

Source for cost estimates: *Holdren et al. 2001 ; ** NYSFOLA, 2009

Appendix B. Summary of Pond Management Alternatives

Appendix B - Category 3: Mitigate Symptoms of Eutrophication - Weeds and Algae (continued)

	Option 4 – Benthic Barriers	Option 5 – Chemical Control Algae	Option 6 – Aquatic Herbicides
Method	Benthic barriers, benthic screens	Chemical control of algae (several copper-based and organic compounds approved for this use)	Chemical control of weeds (Diquat, 2,4-D, Endothol, Glyphosate, Fluridone, Trichlopyr, copper-based herbicides)
How does it work?	Mat of variable composition laid on bottom of target areas. Blocks light and restricts space for plant growth.	Algaecides kill algae by direct toxicity or by metabolic interference	Toxins in contact with or taken up by plant; biochemical pathways disrupted. Ultimately results in plant senescence and death.
Potential Benefits	Used effectively in a variety of lake conditions; can be sited by homeowners.	Rapidly eliminates algae from water column	Reduces density of macrophytes in treated areas.
Potential Drawbacks	Cumbersome to place and anchor. Require maintenance.	Toxic to other organisms; decaying algae may release nutrients, increase oxygen demand. May restrict water uses.	Toxic to other organisms; decaying plants may release nutrients, increase oxygen demand. May restrict water uses.
Data gaps to make decision	Useful for areas where recreational access is limited by weeds	Water pH, alkalinity, background concentrations of metals; sediment quality (AVS and TOC)	Detailed species inventories needed to select most appropriate chemicals
Costs (Relative)	Professional installation $20,000/acre**	Depends on compound: Chelated copper $150 – 300/acre per application*. Copper sulfate $5-$25/acre-foot**.	$200 to $1,500 per acre** Some treatments may need to be repeated. Cost vary with chemical, dose rate, etc.
Permitting issues	Minimal, need to avoid critical habitat Conservation Commission approval needed.	Requires permit and approvals from environmental and public health agencies, including Conservation Commission.	Requires permit and approvals from environmental and public health agencies, including. Conservation Commission
Longevity	Need to be replaced every 1 – 2 years	Short-term (weeks to months)	Annual
Ponds appropriate for this alternative	Areas where homeowners' access is diminishing. Insufficient data..	Insufficient data.	Insufficient data.

Source for cost estimates: *Holdren et al. 2001; **NYSFOLA, 2009

Appendix B - Category 3: Mitigate Symptoms of Eutrophication - Weeds and Algae (continued)

	Option 7 – Biomanipulation	Option 8 – Barley straw
Method	Stocking or removing specific organisms to shift ecological conditions to improve lake for desired uses ("top-down" approach)	Dried barley straw
How does it work?	Stocking fish that eat plankton-eating fish to reduce predation on zooplankton. As a result, zooplankton species increase in size and abundance and feed on more algae, thus controlling algae populations and improving water clarity. Removing bottom-feeding fish that cause turbidity and increase nutrient concentrations by disturbing and consuming organic material at the bottom of the lake.	Dried barley straw, loosely netted to allow maximum oxygen exchange within the straw. Anchored floats hold the netted straw in place in the upper three to four feet of water. Not clearly understood how barley straw affects algae.
Potential Benefits	Serves to achieve multiple water quality objectives while increasing the population of desirable fish species.	Reduces algae levels in ponds and lakes, most effective in controlling new algae growth than at removing pre-existing algae. Public perception that it is "natural" method.
Potential Drawbacks	Results are not easily predictable. May cause unexpected side effects. May control palatable algae and leave blue-green algae.	Not practical for ponds greater than 100 acres. Inconsistent track record. Removing water-logged bales (150 lbs) labor-intensive.
Data gaps to make decision	Experimental procedure. Detailed food web analysis to evaluate appropriateness of using this method to achieve water quality objectives.	Experimental procedure. Water temperatures and temporal patterns of algal blooms during the growing season to optimize deployment of the bales..
Costs (Relative)	$100-$200 per hundred fish. Estimate 100 to 1,000 fish/acre**	Ranges from $20 to $400 per acre, depending on the cost and quantity of straw required.
Permitting issues	Class 2 public stocking license. Conservation Commission approval needed.	Uncertain
Longevity	Depends on whether stocked fish survive and reproduce.	30 to 90 days (based on rate of decomposition of bales)
Ponds appropriate for this alternative	Insufficient data.	Insufficient data.

Source for cost estimates: *Holdren et al. 2001; **NYSFOLA, 2009

Appendix C. Summary of Regulatory Setbacks and Recommendations for Septic Systems in Coastal Areas.

Buzzards Bay Watershed Management Plan	• Recommends 250 ft setback from surface waters and wetlands, (viral pollution) • Where this setback cannot be met, changes in system design and application rate are required to ensure removal of viruses.
New Hampshire's Shoreland Protection Act [3.10 Leach Field And Septic Tank Setback (Added 1990, Amended 1992)]	• "Where the naturally occurring receiving soil down-gradient of the leaching portions of a septic system is a porous sand and gravel material with a percolation rate faster than two (2) minutes per inch, the setback shall be at least 125 feet. • For naturally occurring receiving soils with restrictive layers within 18 inches of the surface, the setback shall be at least 100 feet; and • For naturally occurring receiving soils with any other characteristics the setback shall be at least 75 feet.."
CAMA Handbook For Development In Coastal North Carolina: Section 3	• Septic tanks and drainfields must be located at least 100 feet from waters classified as WS IV by the Environmental Management Commission. • No sewers, septic tank fields or other sources of pollution may be built within 500 feet of the edge of the Fresh Pond in the Nags Head/Kill Devil Hills Fresh Pond watershed. Between 500 feet and 1,200 feet from the pond, septic systems are limited to one system serving a single-family home with no more than four bedrooms (or an equivalent volume of sewage) on a tract of land at least 40,000 square feet in size.
Rhode Island towns:	
Burrillville:	200 ft from wetlands
Charlestown:	• 100 feet from a freshwater or coastal wetland. • 200 feet from a ten-foot-wide flowing body of water. • 100 feet from flowing bodies of water less than 10 feet wide. • 100 feet from intermittent streams. • 100 feet from floodplains.
Foster:	200 ft from any pond, stream, spring or brook
Glocester:	150 ft from ponds, streams or springs
Jamestown:	150 ft from any freshwater
Narrangasett:	Special use permits for septic systems within 150 ft. of coastal and freshwater wetlands.

Appendix C. Summary of Regulatory Setbacks and Recommendations for Septic Systems in Coastal Areas. (continued)

Rhode Island towns (continued):

New Shoreham:	• 150 feet of vegetated buffer shall be maintained from any septic system to a freshwater wetland or coastal feature. • 200 feet of vegetated buffer shall be maintained from any septic system to Sands Pond, Peckham Pond and Fresh Pond.
Scituate:	150 ft from surface waters
South Kingstown:	Requires special use permits for all septic systems located: • Within 50 feet of a bog, marsh, swamp or pond. • Within 200 feet of flowing bodies of water 10 feet or more in width. • Within 100 feet of flowing bodies of water less than 10 feet in width. • Within 150 feet of floodplains. • Within 150 feet of other freshwater wetlands
Warren:	150 ft from any body of water, including wetlands
West Greenwich:	200 ft from edge of any pond or stream

Appendix D. Recommended Water Quality Monitoring Program

As described in Eichner et al (2008), there is currently no on-going water quality monitoring program to track the condition of Barnstable's inland kettle ponds. Monitoring can be a costly and time-consuming endeavor; therefore, we recommend a focused monitoring program clearly linked to specific management objectives. This focused monitoring program will provide strategic information regarding the water quality and ecological status of the Barnstable freshwater ponds. Measuring various physical, chemical, and biological attributes of the inland ponds can help municipal leaders and other stakeholders evaluate use attainment, trends and the effectiveness of control measures.

- *Recommended Action: Conduct water quality monitoring using the established PALS protocol on a three-year rotation*

Objective: Develop a program to sample priority ponds on a three-year cycle. This will enable comparisons between ponds and within ponds over time.

- *Recommended Action: Measure water quality conditions in the upper and lower waters of Lovells, Wequaquet and Mystic Ponds from April – October, 2010*

Objective: Evaluate the magnitude and importance of sediment TP flux in deep ponds affected by increased productivity.

Rationale: Internal sediment TP can be remediated for a period of a decade or more with an alum treatment program. For this treatment to be effective, internal TP flux during summer anoxia must be a significant fraction of the TP budget. Moreover, TP released from sediment must reach the upper, sunlit waters where algal production occurs.

Parameter list:

Parameter	Depth	Frequency	Note
TP, TN, total alkalinity	3 m intervals through water column	Monthly (minimum) Biweekly(recommended)	Discrete samples
DO, temperature, pH, specific conductance	1 m intervals through water column	Monthly (minimum) Biweekly(recommended)	Field meter
Secchi disk transparency	From surface	Biweekly	Volunteer monitoring possibility
Chlorophyll-*a*	Composite sample through photic zone	Monthly (minimum) Biweekly(recommended)	

Recommended Action (2): Develop a surveillance program for cyanobacterial blooms

Objective: Adopt a reliable near-real time technique for evaluating whether the public is at risk from harmful algal blooms.

Rationale: Certain species of cyanobacteria (blue-green algae) can exude potentially harmful compounds. Restrictions on swimming during bloom conditions may be warranted to protect public health. Sampling and analysis of the algal community can be costly if in-house expertise is not available, and may extend over several days before results are received and interpreted. A field meter to screen for the presence and concentration of phycocyanin, a pigment associated with cyanobacterial blooms, may provide a screening tool.

RE: 2020 Wastewater Plan MEP Scenarios: Additional 3 Bays Sewering and Barnstable Great Marshes Impact

I. Background

The Town of Barnstable is working to evaluate and implement a Wastewater Plan that includes reducing excessive nitrogen loads to its coastal estuary waters. The Town of Barnstable has proposed a 30-year, three-phased wastewater plan that uses and builds on the existing wastewater infrastructure, including the municipal Barnstable Water Pollution Control Facility (WPCF).[1] This proposed plan is flexible depending on future changes.

At the request of the Town, the project team evaluated the estuarine water quality impacts of potential Wastewater Plan sewering within the watersheds to Lewis Bay, Centerville River, Three Bays, and Barnstable Great Marshes.[2] These 2019 evaluations included updating most watershed nitrogen loads to current conditions based on updates of land uses, impervious surfaces, and wastewater flows within the Massachusetts Estuaries Project (MEP) linked models for these estuaries.[3] Once this update was complete, the watershed loads were then adjusted to reflect planned sewering under the Wastewater Plan. The hydrodynamic portions of the linked models continued to use the MEP-developed versions.

[2] CSP/SMAST Technical Memorandum. December 5, 2019. MEP Scenarios: Town of Barnstable Wastewater Plan and Land Use Updates. To: G. Beaudoin, Town Engineer, Barnstable Department of Public Works. From: B. Howes, E. Eichner, and J. Ramsey. 36 pp.

[3] MEP assessments for Three Bays, Centerville River, Lewis Bay/Halls Creek, and Barnstable Great Marshes were completed in 2006, 2006, 2008, and 2017, respectively. During the 2019 project, land uses in adjacent towns that share the system watersheds were not updated and land uses and nitrogen loads within these towns continued to be those developed during the MEP.

These 2019 evaluations generally found that the planned sewering included in the Wastewater Plan attained the nitrogen reductions to restore the water quality[4] in these estuarine systems except for the Three Bays system. As a result, the Town has proposed additional sewering within the Three Bays watershed and has asked the project team to update some key watershed nitrogen loads. These changes would be incorporated into the updated 2019 Three Bay MEP model. Since a portion of the collected sewer flow with the Three Bays watershed would be treated at the municipal Barnstable Water Pollution Control Facility (WPCF) and discharged within the Barnstable Great Marshes watershed, the Town has also asked the project team to evaluate the impact of this additional nitrogen load on the Barnstable Great Marshes system as well.

II. Three Bays Scenario: Additional Watershed Sewering

The final MEP assessment report on the Three Bays estuary system was completed in 2006[5] and MassDEP used the MEP assessment to develop and approve a set of nitrogen TMDLs for restoring water quality in the Three Bays system in 2007.[6] The watershed nitrogen loading model portion of the linked Three Bays MEP models was based on digital parcels and land use data obtained from the watershed towns for the following years: 2004 for Barnstable, 2000 for Sandwich, and 2001 for Mashpee. Tidal data, bathymetry, and shoreline configuration for the linked Three Bays MEP water quality model were collected in 2002 and water quality data that was used was collected between 1999 and 2004. Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that portions of the system ranged in condition from severely degraded (Warrens Cove, Princes Cove, Upper North Bay) to moderately impaired (Cotuit Bay, West Bay).[7]

The 2019 watershed loading update showed an increased (+4.8%) *attenuated* system-wide nitrogen load under current conditions compared to the MEP system load. In contrast, there was little change (+0.6%) in the system *unattenuated* load compared to the MEP load. The relatively higher increase in the attenuated loads was due to changes in the spatial distribution of the loads within the watershed with relatively greater loading increases in the lower portion of the watershed closer to the estuary.

In order to attain the Three Bays TMDL restoration targets, the proposed 2019 Town Wastewater Plan scenario included provisions to decrease watershed nitrogen loads by connecting large portions of the Three Bays watershed to a municipal sewer system (**Figure 1**). Working with the project team, Town staff also included in this scenario an additional provision to split the collected wastewater between the Barnstable WPCF and an as-yet-undetermined site along a north/south line through the watershed. Any collected wastewater east of line would be treated at the WPCF. The proposed sewering in the 2019 Plan significantly decreased the watershed-wide attenuated load by -39% with the majority of the decrease occurring within the combined Prince Cove

[4] The Massachusetts Department of Environmental Protection has developed total nitrogen limits (Total Maximum Daily Loads or TMDLs) for Three Bays, Centerville River, and Lewis Bay based on MEP assessments. Portions of Barnstable Great Marshes were identified as impaired in its MEP assessment, but MassDEP has not developed a nitrogen TMDL for it yet.

[5] Howes B., S.W. Kelley, J.S. Ramsey, R. Samimy, D. Schlezinger, E. Eichner. 2006. Linked Watershed-Embayment Model to Determine Critical Nitrogen Loading Thresholds for Three Bays, Barnstable, Massachusetts. Massachusetts Estuaries Project. Massachusetts Department of Environmental Protection. Boston, MA. 183 pp.

[6] MassDEP. 2007. Three Bays System TMDLs for Total Nitrogen (Report # MA96-TMDL-10, Control # CN242.0). 35 pp. Approved by USEPA, February 13, 2008, 6 total nitrogen TMDLs, 1 pollution prevention total nitrogen TMDL.

[7] See Table VIII-1 in Three Bays MEP Report (Howes and others, 2006).

subwatershed. However, the reduction was insufficient to attain the 0.38 mg/L total nitrogen (TN) threshold concentration in the Three Bay TMDL at the sentinel water quality monitoring station.

In order to meet the TMDL target and further discussions with project staff, Town staff expanded the Three Bays sewer areas in the current 2020 scenario to include four new areas, mostly within the subwatersheds to the following waters: 1) West Bay, 2) Cotuit Bay, 3) Shubael Pond, and 4) Long Pond (Marstons Mills) (see **Figure 1**). Collectively, these additional sewered areas added 736 additional sewered parcels within the Three Bays watershed to those identified in the 2019 scenario. Water use at these parcels was 160,307 gallon per day (gpd) with 99,297 gpd of this flow to be treated at the WPCF and the remainder at an as-yet-undetermined site.

In addition to the new sewering, Town staff also asked CSP/SMAST staff to update nitrogen loads from the four golf courses in the watershed and the nitrogen load from the capped Town landfill. Town staff contacted all the golf superintendents and obtained recent nitrogen fertilizer application rates.[8] These updated nitrogen fertilizer application rates were all less than those used in the original MEP watershed nitrogen loading.[9] Updated Town landfill monitoring data from 2012 to 2016 was incorporated in the 2019 watershed nitrogen loading update, but the monitoring results suggested a decreasing nitrate-N trend. More recent data provided for this 2020 scenario confirmed that concentrations had decreased further since 2016 (**Figure 2**). The combined impact of incorporating the landfill and golf course fertilizer updates decreased the overall attenuated nitrogen loads in the Three Bays watershed by 1,540 kg/yr.

The total *unattenuated* nitrogen load removed from the Three Bays watershed as a result of this additional 2020 sewering and the landfill and golf course fertilizer updates was 6,343 kg/yr (**Table 1**). Most of this removal (42%) occurred in the West Bay subwatershed with similar portions in Cotuit Bay (23%) and Prince Cove (26%). As a result of the 2020 changes, the total *attenuated* nitrogen load removed from the Three Bays watershed was 5,325 kg/yr (see **Table 1**). Most of this attenuated removal (50%) occurred in the West Bay subwatershed with 20% removal in the Cotuit Bay subwatershed, 19% in Prince Cove, 10% in North Bay, and 1% in the Seapuit River. It should be noted that the attenuated nitrogen removals from sewering within the watersheds to Shubael Pond and Long Pond (Marstons Mills) were reduced because these ponds naturally attenuate 50% of the nitrogen within their watersheds, so sewering only removes half of the wastewater nitrogen compared to watersheds with direct discharge to the estuary without natural nitrogen attenuation. This upstream attenuation reduced the impact of sewering within the Prince Cove subwatershed. Overall, the 2019 plan attenuated watershed loads were a 44% reduction from the 2019 existing conditions update loads, while the 2020 plan loads were a 54% reduction (**Table 2**). The accompanying benthic loads also decreased.

As a result of the 2020 additional reductions, the TN concentration at the Three Bays sentinel station was attained (**Table 3**). The 2019 updated conditions caused TN concentrations to increase throughout the Three Bays system using the MEP Linked Watershed-Embayment Nitrogen Management Model; the TN concentration at the sentinel station increase from 0.487 mg/L under the MEP existing conditions to 0.499 mg/L TN with the updated conditions. The 2019 wastewater plan nitrogen reduction reduced the TN concentration throughout the Three Bays system, but had

[8] Personal communication, A. Unruh, Barnstable DPW.

[9] Project staff have found reduced golf course fertilizer applications in a number of other MEP updates in the region.

a 0.408 mg/L TN concentration at the sentinel station, which did not attain the 0.380 mg/L TN threshold target/TMDL. The additional nitrogen reductions included in the 2020 wastewater plan resulted in reduction in TN concentrations throughout the Three Bay system and attained the TN threshold at the sentinel station. The largest reductions in concentration were generally in the inner portions of the system: Prince Cove – south (-33%), Prince Cove – north (-31%), Warrens Cove (-28%) and North Bay – north (-22%).

It should be noted that the nitrogen loads and concentrations do not include buildout provisions or updates to Sandwich loads (except for the golf courses). The MEP buildout assessment for Three Bays estimated that the watershed load would increase by 12%.[10] Some of the projected portion of the buildout within the Town of Barnstable was included in the 2019/2020 updates, but Sandwich loads do not included any potential buildout since this portion of the watershed load was generally the same as the MEP load.

III. Barnstable Great Marshes/Bass Hole Scenario: Additional WPCF N Loading

The final MEP assessment report on the Barnstable Great Marshes estuary system was completed in 2017.[11] The watershed nitrogen loading model portion of the MEP linked models was based on digital parcels and land use data with base years between 2011 and 2012 that were obtained from the watershed towns of Barnstable, Yarmouth, Dennis, and Sandwich. Bathymetry and salt marsh topography for the water quality model portion of the MEP linked models were collected in 2015 and 2013, respectively. Water quality data between 2002 and 2014 was used in the development of the model. Measurements of dissolved oxygen, chlorophyll, macroalgae, eelgrass, and infauna found that the majority of the system had healthy habitat except for the Millway subembayment, which is a dredged boat basin with severely degraded habitat.[12] The MEP team recommended a target bioactive nitrogen concentration at the Millway to address its measured nitrogen-related impairments, but found that the majority of the Barnstable Great Marshes system could accommodate a +39.6% increase in watershed nitrogen loads without becoming impaired.[13] MassDEP has not developed a draft nitrogen TMDL for Barnstable Great Marshes or the Millway.

The 2019 watershed nitrogen loading model update included a number of revised inputs, including a new accounting of the municipal sewer connections to the Barnstable WPCF within Barnstable Village, which included parcels within the Millway subwatershed. Overall, the 2019 update had total system unattenuated and attenuated loads within 1% of the corresponding MEP loads.

The 2019 Town Wastewater Plan scenario included provisions that added treated effluent flows from the Barnstable WPCF to a location within the Barnstable Harbor watershed. The Plan scenario specified that treated wastewater at the Barnstable WPCF site would total 3.82 MGD, but effluent discharge at the WPCF site would be limited to 2 MGD (with a 3 mg/L TN concentration). The remaining treated effluent would include 1.2 MGD discharged within the Barnstable Great Marshes watershed and 0.62 MGD that would be collected within Yarmouth, treated at the WPCF,

[10] See Table IV-5 in Three Bays MEP Report (Howes and others, 2006).

[11] Howes B., E. Eichner, S. Kelley, R. Samimy, J. S. Ramsey, D. Schlezinger, P. Detjens. 2017. Massachusetts Estuaries Project Linked Watershed-Embayment Model to Determine the Critical Nitrogen Loading Threshold for the Barnstable Great Marshes - Bass Hole Estuarine System, Towns of Barnstable and Dennis, Massachusetts, Massachusetts Department of Environmental Protection. Boston, MA. 213 pp.

[12] See Table VIII-1 in Barnstable Great Marshes/Bass Hole MEP Report (Howes and others, 2017).

[13] See Table VIII-3 in Barnstable Great Marshes/Bass Hole MEP Report (Howes and others, 2017).

and returned to Yarmouth for discharge outside of the Lewis Bay watershed. Treated effluent discharge at the WPCF and the Barnstable Harbor watershed would include portions of the collected wastewater within the Three Bays, Centerville River, Lewis Bay, and Barnstable Great Marshes watersheds.

The additional collected wastewater within the Three Bays watershed in the 2020 scenario discussed in this memo would add 99,297 gpd to the WPCF treated effluent discharge within the Barnstable Great Marshes watershed. This addition would increase the treated effluent discharge from 1.2 MGD to 1.3 MGD. This change would result in a nitrogen loading increase of 412 kg/yr or a 0.6% increase in the overall attenuated watershed load from the 2019 Wastewater Plan scenario (**Table 4**). The benthic load also changes slightly too (**Table 5**).

As would be expected by such a small change in a large watershed load, the change in the impact of this addition generally does not change the TN concentrations throughout the Barnstable Great Marshes (**Table 6**). The only monitoring station with any change was the Broad Sound station (BM-10), which is predicted to increase from 0.107 mg/L TN to 0.108 mg/L TN. No changes were modeled at the sentinel stations as a result of the small addition of WPCF treated effluent and all projected concentrations remained below the MEP thresholds at these stations.

III. Conclusions/Discussion

At the request from the Town of Barnstable, project staff reviewed the impact of additional 2020 projected sewering within the Three Bays watershed. This scenario also included updates to the nitrogen loads from the town landfill, as well as updates of nitrogen fertilizer applications at the four golf courses within the Three Bays watershed. The additional projected sewering resulted in additional wastewater flow being transferred to the Water Pollution Control Facility (WPCF). This resulted in an additional scenario to evaluate the impact of this small amount of additional treated effluent being discharged within the Barnstable Great Marshes watershed.

These two scenarios were completed using the MEP linked models for the Three Bays and Barnstable Great Marshes systems. The Barnstable watershed nitrogen loading portions of these models were previously updated to 2019 land use and used to evaluate the impacts a 2019 version of the Town's Wastewater Plan within all four of the Town's estuary systems.[14]

The 2020 sewer additions and nitrogen loading updates within the Three Bays watershed allowed the Wastewater Plan scenario to attain the MEP nitrogen thresholds/MassDEP TMDLs at the Three Bays sentinel stations. The small nitrogen loading addition within the Barnstable Great Marshes system had little impact on the watershed nitrogen load and projected nitrogen concentrations continued to attain the MEP nitrogen thresholds throughout the Barnstable Great Marshes system.

[14] CSP/SMAST Technical Memorandum. December 5, 2019.

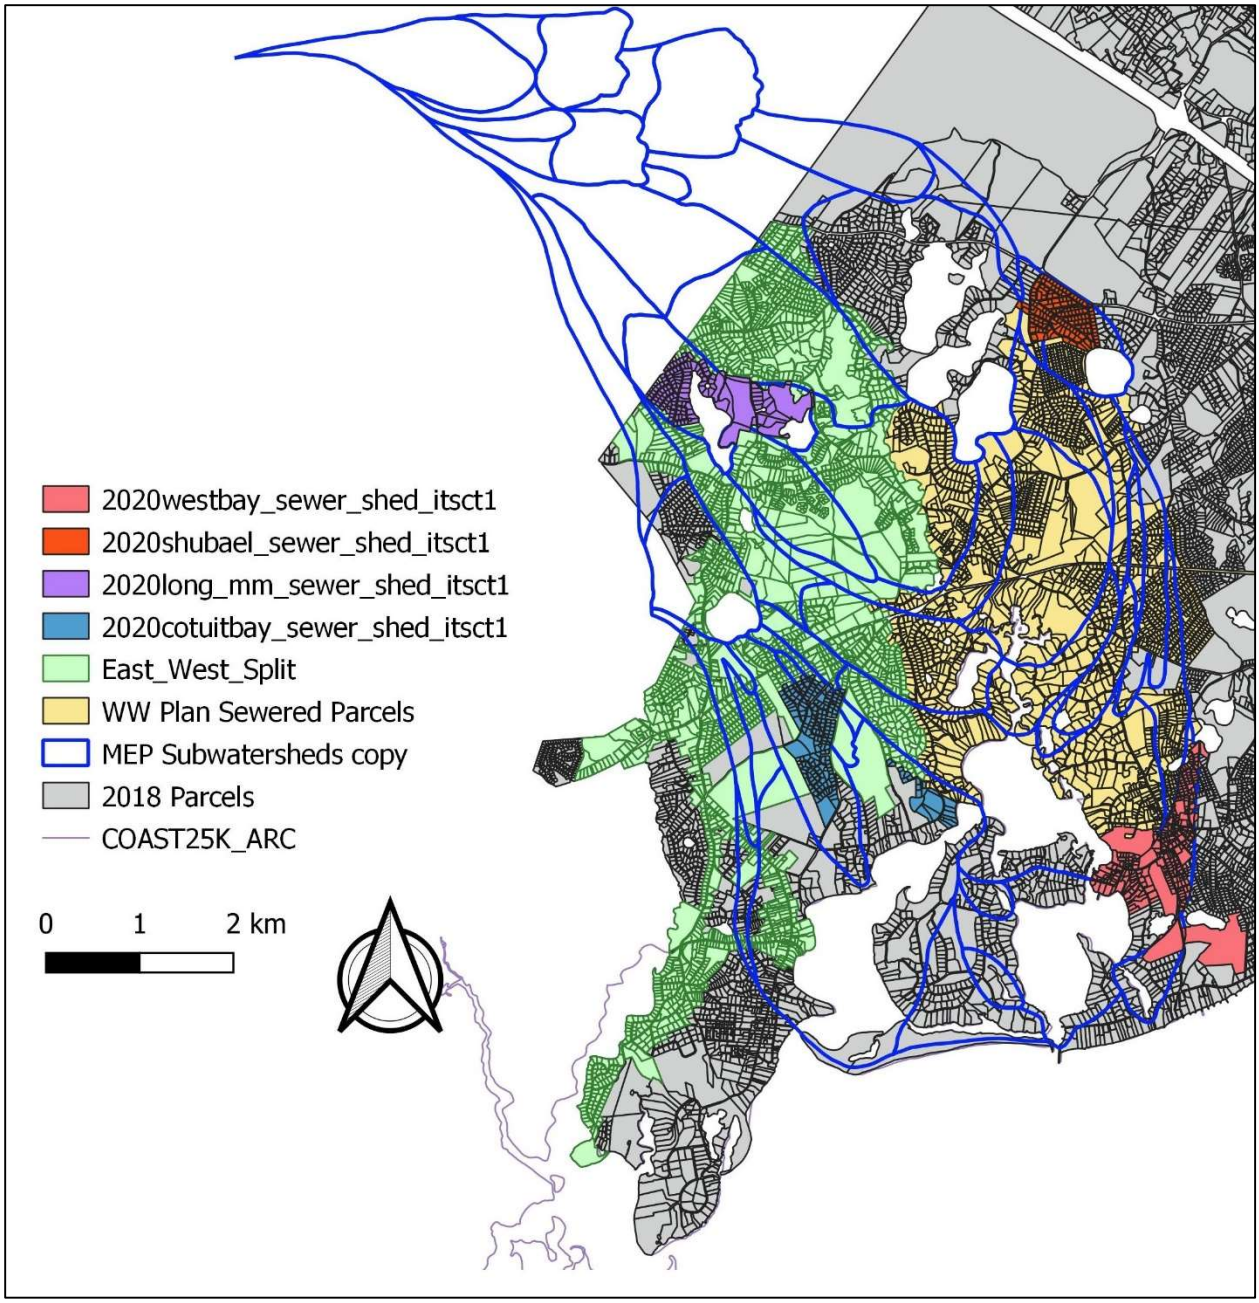

Figure 1. 2020 Sewer Area Additions to Three Bays Watershed. In 2019, the Town Wastewater Plan included connecting the yellow parcels (WW Plan Sewered Parcels) and the green parcels (East_West_Split) to a municipal sewer system. Wastewater from the yellow parcels would be treated at the Barnstable WPCF, while wastewater from the green parcels would be treated and discharged at an as-yet-to-be-determined site outside of the Three Bays watershed. In the 2020 scenario, Town staff have added additional sewered parcels in four areas generally within the subwatersheds to West Bay, Cotuit Bay, Shubael Pond, and Long Pond (Marstons Mills). Collected wastewater from the West Bay and Shubael Pond sewered areas would be treated at the Barnstable WPCF, while the wastewater from the Cotuit Bay and Long Pond (Marstons Mills) sewered area would be treated at as-yet-to-be-determined site outside of the Three Bays watershed.

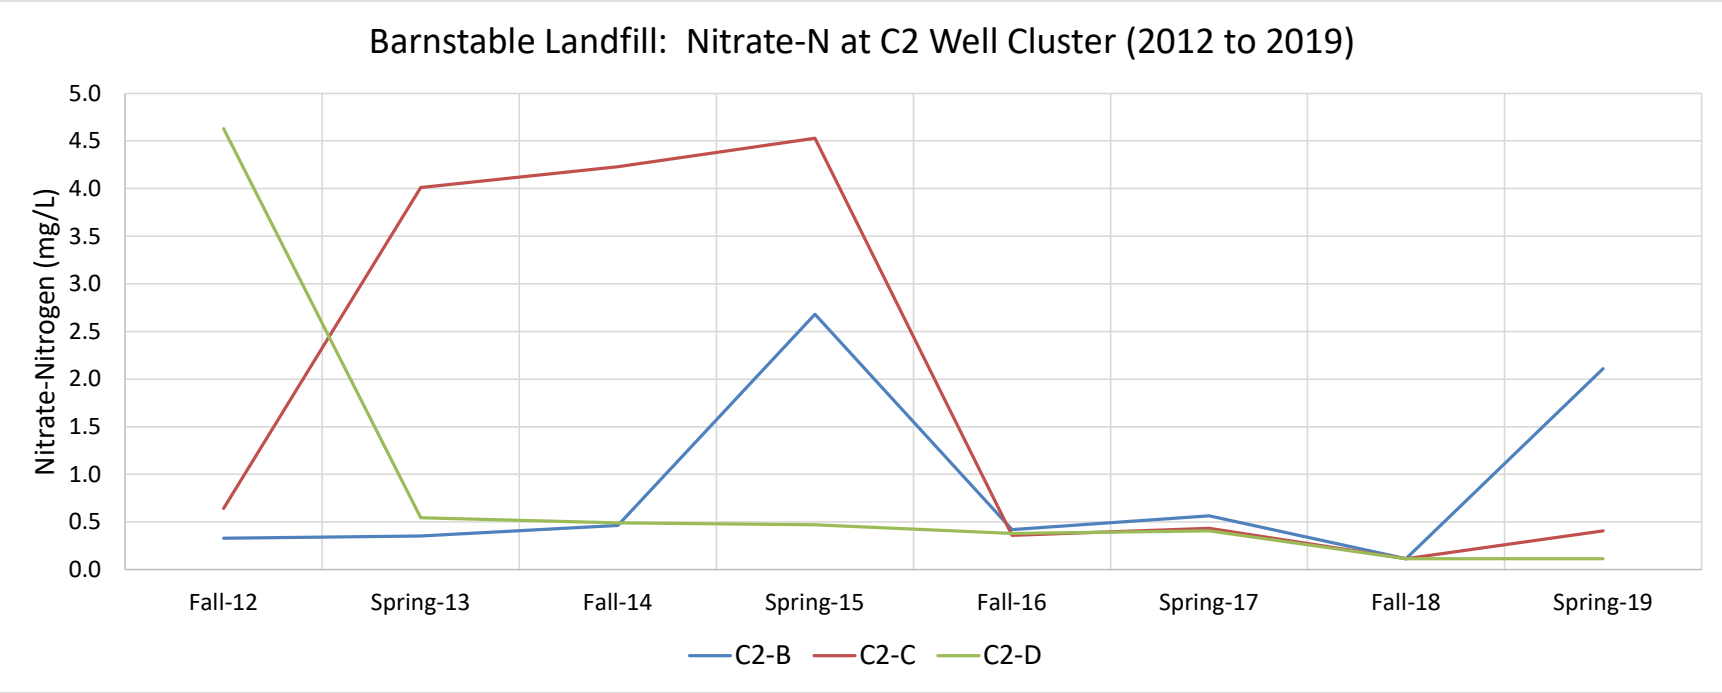

Figure 2. Nitrate-Nitrogen Concentrations in C2 Well Cluster at Barnstable Landfill (2012 to 2019). In the 2019 watershed nitrogen loading update of the Three Bay MEP model, project staff received monitoring data at the capped Town landfill from Town staff**.** The 2019 update included data from 2012 to 2016, but the low concentrations in Fall 2016 suggested that the nitrogen contamination from the landfill might be decreasing further. As part of the 2020 update discussed in this technical memo, project staff received data from three additional sampling runs at the landfill and included the resulting decreased landfill nitrogen load in the 2020 scenario (-560 kg/yr unattenuated nitrogen load).

Table 1. Watershed Nitrogen Loads for Three Bays Scenarios: 2019 Land Use Update, 2019 Town Wastewater Plan and 2020 Wastewater Plan with Sewer Additions. The 2019 update of watershed parcels, water use, impervious surfaces, etc. increased the attenuated nitrogen load of the overall system watershed by 5.5% and the unattenuated load by 0.8% compared to the MEP loads. The 2019 Town Wastewater Plan decreased the attenuated load by 44% with the majority of the decrease within the Prince Cove subwatershed. The 2020 Sewer Additions were in the subwatersheds to: West Bay, Cotuit Bay, Shubael Pond, and Long Pond (Marstons Mills). The additional sewering resulted in a 3,786 kg/yr reduction in the attenuated system load. Loads in this table do not include nitrogen deposition on the estuary surfaces.

Scenario	Description	Watershed/ Subwatershed	Wastewater		Fertilizers	Impervious Surfaces	Water Surface	Natural Surfaces	Total N Load	
			Septic	WWTF					Unatten	Atten
			kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr

Table 2. Watershed, Benthic Flux, and Direct Atmospheric Nitrogen Loads for Three Bays Scenarios: MEP, 2019 Current Conditions Land Use Update, 2019 Town Wastewater Plan and 2020 Wastewater Plan with Sewer Additions, Golf Course Fertilizer Updates, and Landfill Updates. These are the nitrogen loads used in the water quality modeling of each scenario, including the 2020 scenarios discussed in this Technical Memo. The 2020 sewer additions were within the West Bay, Cotuit Bay, Shubael Pond, and Long Pond (Marstons Mills) subwatersheds and were combined with updated nitrogen application rates for the four golf courses in the watershed and an updated nitrogen load from the capped Town landfill. Direct atmospheric deposition loads are nitrogen loads on the surface of each of the subembayments. Net benthic flux loads are nitrogen regenerated from sediments within each subembayment. The 2019 loads were described in a December 5, 2019 CSP/SMAST Technical Memo. Nitrogen loads from the 2006 MEP Report are also shown for comparison. All nitrogen loads are presented as kilograms per day and may not sum correctly due to rounding.

	Total Attenuated Watershed Loads (kg/d N)				% change from 2019 Current Conditions Update		Benthic Flux Net (kg/d N)			direct atmospheric deposition (kg/day N)	
Sub-Embayment	MEP	2019 Current Conditions Update	2019 WW Plan	2020 Plan w/Sewer Additions, GC and landfill changes	2019 WW Plan	2020 Plan w/Sewer Additions	2019 Update	2019 WW Plan	2020 Plan w/Sewer Additions	MEP	2019 Update + both scenarios
Cotuit Bay	21.78	23.03	16.27	14.90	-29%	-35%	-55.96	-46.29	-44.06	5.79	5.79

Table 4. Watershed Nitrogen Loads for Barnstable Great Marshes Scenarios: MEP, 2019 Land Use Update, 2019 Town Wastewater Plan and 2020 Wastewater Plan with Sewer Additions. The 2019 current conditions update of watershed parcels, water use, impervious surfaces, additional sewer connections, etc. had negligible impact on the overall unattenuated and attenuated system loads (<1% change). The 2019 Town Wastewater Plan scenario increased the attenuated system load by 1.3%, but decreased the Millway subwatershed load by 53%. *Millway (part of Great Marshes – E) was the only portion of the Great Marsh system that was identified as impaired in the MEP assessment. The 2020 Sewer Additions scenario included additional sewering within the Three Bays watershed and discharge of the treated flows (99,297 gallons per day) within the Barnstable Great Marshes watershed. Under the Wastewater Plan, these flows are treated at the WPCF, but site effluent discharge is capped at 2 million gallons per day. The additional Three Bays sewering in the 2020 Wastewater Plan increases the Barnstable Great Marshes watershed nitrogen load by 412 kg/yr (wastewater only) or a 0.6% increase in the overall watershed load from the 2019 Wastewater Plan scenario. Loads in this table do not include nitrogen deposition on the estuary surfaces.

Scenario	Description	Watershed/ Subwatershed	Wastewater		Fertilizers + Farm Animals	Impervious Surfaces	Water Surface	Natural Surfaces	Total N Load	
			Septic	WWTF					Unatten	Atten
			kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr	kg/yr

Table 5. Watershed, Benthic Flux, and Direct Atmospheric Nitrogen Loads for Barnstable Great Marshes Scenarios: MEP, 2019 Land Use Update, 2019 Town Wastewater Plan and 2020 Wastewater Plan with Sewer Additions. These are the nitrogen loads used in the water quality modeling of each scenario. Subwatershed loads include all nitrogen sources, including septic wastewater loads, impervious surface runoff, and lawn fertilizers. Direct atmospheric deposition loads are nitrogen loads on the surface of each of the subembayments. Net benthic flux loads are nitrogen regenerated from sediments within each subembayment. MEP nitrogen loads from the 2017 Report are also shown for comparison. The 2020 Wastewater Plan with Sewer Additions scenario had small watershed and benthic load additions to the Barnstable Harbor – mid subembayments. All nitrogen loads are presented as kilograms per day.

	Total Attenuated Watershed Loads (kg/d N)				% change from 2019 Current Conditions Update		Benthic Flux Net (kg/d N)			direct atmospheric deposition (kg/day N)

Table 6. Comparison of modeled average bioactive N concentrations for Barnstable Great Marshes system: MEP, 2019 Land Use Update, 2019 Town Wastewater Plan and 2020 Wastewater Plan with Sewer Additions. The sentinel station thresholds are 0.16 mg/L bioactive N at sentinel stations located in salt marsh dominated basins and 0.21 mg/L bioactive N within the Millway, a dredged basin; the selected monitoring stations and the threshold targets are shown in **bold** print. Both the 2019 Wastewater Plan scenario and the 2020 Wastewater Plan with Sewer Additions attained the threshold targets at each of the sentinel stations. Bioactive nitrogen is used instead of TN in large systems, like Barnstable Great Marshes and Pleasant Bay, where there is a lot of non-active dissolved organic nitrogen and habitat and water quality are determined by the most active forms (inorganic and particulate nitrogen). Note that values shown are rounded.

Appendix TT

Barnstable CWMP - Climate Adaptation and Resiliency Approach

WRIGHT-PIERCE
Engineering a Better Environment

MEMORANDUM

TO:	Griffin Beaudoin – Town of Barnstable	**DATE:**	10/29/2020
FROM:	Ed Leonard; Corey Lewis	**PROJECT NO.:**	20157C
SUBJECT:	Barnstable CWMP - Climate Adaptation and Resiliency Approach		

BACKGROUND AND PURPOSE

The Town of Barnstable submitted its Comprehensive Wastewater Management Plan (CWMP) for review under the Massachusetts Environmental Policy Act (MEPA). The Executive Office of Energy and Environmental Affairs (EOEEA) issued a Certificate of the Secretary of the EOEEA on the Expanded Environmental Notification Form (EENF) dated April 3, 2020 which identified certain additional information required to complete the review. Select relevant text from the Certificate is indicated below:

- "The Town of Barnstable, Massachusetts is a participant in the Commonwealth's Municipal Vulnerability Preparedness (MVP) program. The MVP program is a community-driven process to define natural and climate-related hazards, identify existing and future vulnerabilities and strengths of infrastructure, environmental resources and vulnerable populations, and develop, prioritize and implement specific actions the Town can take to reduce risk and build resilience."
- "Components of the wastewater collection infrastructure, such as proposed pump station sites, appear to be located within coastal flood zones."
- "The Single EIR should discuss climate resiliency considerations made in designing and implementing other components of the CWMP, including the siting and construction of new sewer mains."

The Town intends to leverage the MVP program and the best available data on climate change predictions, to develop climate change scenarios that could affect wastewater infrastructure and identify potential adaptation measures as part of its CWMP.

The purpose of this technical memorandum is to outline the general approach that the Town will use in designing and implementing sewer mains, pump stations and forcemains as a part of the CWMP.

CLIMATE ADAPTATION AND RESILIENCY APPROACH

Some components of the Town's existing and proposed wastewater collection infrastructure, such as proposed pump station sites and sewer extensions, appear to be located within coastal flood zones and/or areas that may also be affected by future climate change related stressors. The following approach is suggested as a supplement to the MVP program while the Town is conducting pre-design and design activities for projects that will result from the CWMP. This approach can be applied to both new and existing infrastructure.

Participating Personnel

The first step in the wastewater infrastructure climate resiliency planning approach should include the identification of Town personnel and stakeholders that will be part of the resiliency planning process, their roles and responsibilities and level of involvement in the decision-making process. The stakeholder group should include:

- Town wastewater system administrative and operational staff members;
- Key Town decision-makers, including administrative, planning and financial staff;
- Relevant Local, State and Federal regulatory entities;
- Community stakeholders;
- Relevant consultants, as needed.

Preliminary Climate-Related Hazard and Infrastructure Reconnaissance

The Town should collect the best available data on climate change predictions and additional resources listed below to assist with evaluating and selecting the most appropriate adaptation measures for wastewater infrastructure.

- A review of readily available information on applicable climate-related hazards and wastewater infrastructure technical information:
    - Interviews with Town wastewater field personnel familiar with the Town's existing wastewater system components;
    - Historic local weather patterns, precipitation data and flooding information;
    - Existing infrastructure operational and maintenance data and procedures;
    - Town GIS maps and databases, wastewater and utility support systems record drawings, and any available conceptual or preliminary site plans and data for planned future infrastructure and land development;

  - Floodplain mapping, future climate scenario models, reports and resources including Federal Emergency Management Agency (FEMA) floodplain maps and GIS data, EEA's Climate Change Adaptation Report (September 2011), the Town's Climate Change Vulnerability Assessment (dated December, 2019) and other pertinent information available on the www.resilientMA.org website.
  - Current wastewater industry and regulatory design standards for critical and non-critical infrastructure, such as the New England Interstate Water Pollution Control Conference's *TR-16: Guides for the Design of Wastewater Treatment Works* guidance on wastewater infrastructure design and flood protection.
- Supplemental field reconnaissance such as aerial/drone site imagery, topographic survey, infrastructure elevation truthing and data gathering for critical infrastructure components.

Data and Hazard Evaluation

The Town should review the data and conduct a climate-related hazard evaluation including:

- Review of floodplain inundation using best available climate scenarios and modeling compared to existing and planned critical assets to identify and assess potential threats to infrastructure reliability as well as the ability to safely access and operate critical infrastructure during periods of inundation and utility power loss.
- Review the present and future impacts on critical infrastructure from changing precipitation patterns and storm intensity, duration and frequency.
- Review of any potential vulnerabilities in community or utility support systems that may be impacted by potential climate hazards and the consequences on the Town's system reliability. This should include a review of any known potential or planned future development and its cumulative impacts on utility support system capacity and demand.
- Review of potential impacts from wind-related hazards (e.g., falling trees, utility poles, wires) may have on existing critical infrastructure and how it may affect site planning for proposed infrastructure.
- Assessment of current and planned infrastructure redundancy and resiliency components.

Much of this work was documented for existing pump stations in the report entitled "Wastewater Pump Station Asset Management Plan" (Wright-Pierce, December 2019).

An example of climate-related hazards and their potential impacts on wastewater system reliability is included in Table 1. Potential climate-related hazards and infrastructure vulnerabilities identified during the evaluation phase should then be subjected to a hazard consequence risk assessment.

TABLE 1
POTENTIAL CLIMATE-RELATED HAZARD CONSEQUENCES

Climate Change Impact	Potential Hazards	Hazard Consequences
Sea Level Rise and Increased Flood Risk	River Flooding	• Localized flooding or ponding • Accessibility issues from temporary flooding • Soil erosion • Water leaks into enclosures, electrical equipment and conduits • Increased I/I to collection system and pump stations • SSOs from elevated groundwater or surface water intrusion exceeding system capacity
	Coastal Flooding	
	Flash Flooding	
Storm Characteristics	Increased Precipitation Intensity	• Localized flooding or ponding • Accessibility issues from temporary flooding • Soil erosion • Water leaks into enclosures, electrical equipment and conduits • Poor travel conditions • Utility power outages • Hazardous working conditions • Increased I/I to collection system and pump stations • Increased snow loading to enclosures • Accessibility issues from excess snowfall • SSOs from wet-weather flows exceeding system capacity
	Increased Precipitation Duration	
	Increased Precipitation Frequency	
	Excessive Wind Speeds	• Utility power outages • Increased wind loading to enclosures and panels • Downed trees causing equipment damage.

Hazard Risk Assessment

The hazard risk assessment leverages the available climate-related hazard and infrastructure information to assess the likelihood of climate-related hazard consequences (e.g., sewer system inundation, pump station failure, etc.) and their potential impacts on wastewater system reliability and the community at large. Potential hazard consequences and their impact on the associated assets are assessed to determine their likelihood of occurring and to help prioritize adaptation measures.

As a first step of the hazard risk assessment process, critical wastewater system components should be identified based on their importance to achieving the Town's goals of reliably serving its customers, meeting regulatory obligations, and providing a safe working environment for the Town staff. Critical wastewater components typically include the wastewater treatment facilities, pump stations, and sewer collection system main pipelines and interceptor sewers. The critical system components should then be subjected to a screening-level assessment to determine whether the asset is potentially vulnerable to the climate-related hazards, and if so, whether the asset has built-in resiliency measures that would reduce the potential hazard consequence risk. Risk is generally defined as (likelihood x impact), so the risk assessment addresses both the likelihood of the hazard occurring and the impact on the asset if it did occur. Examples of the iterative screening-level risk assessment process are depicted in the figures below and the following bulleted list.

FIGURE 1: SCREENING-LEVEL HAZARD RISK ASSESSMENT (EXAMPLE)

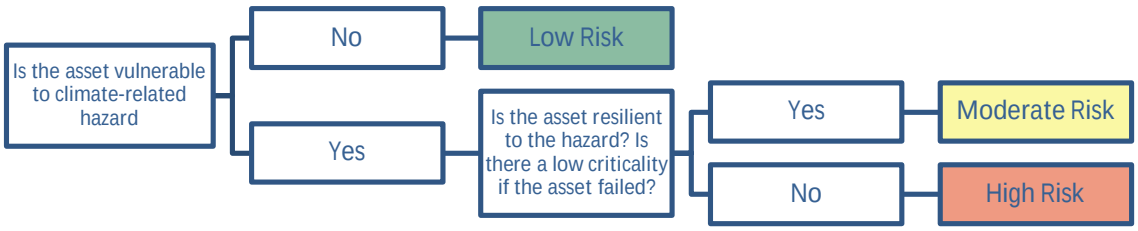

FIGURE 2: INTERCEPTOR SEWER FLOOD RISK ASSESSMENT (EXAMPLE)

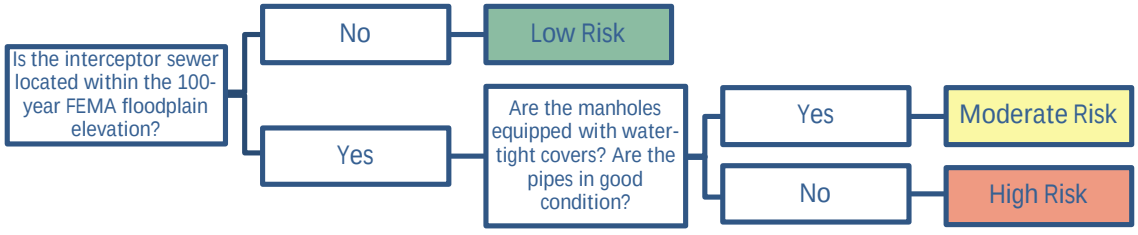

FIGURE 3: PUMP STATION UTILITY POWER OUTAGE HAZARD RISK ASSESSMENT (EXAMPLE)

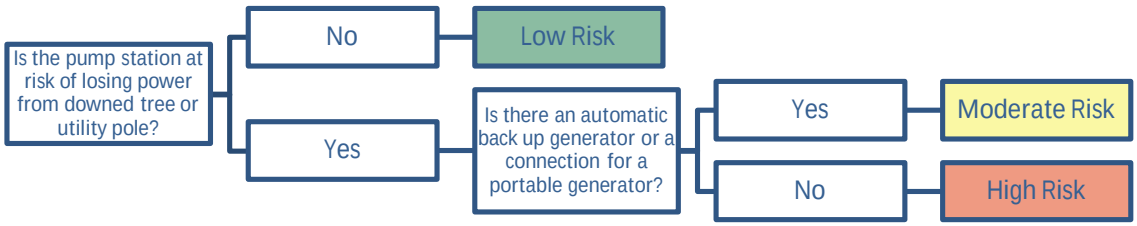

The following are additional examples of iterative screening-level questions to determine risk:

- What is the significance of the asset? Stated another way, how critical would it be if the asset failed or was impacted by a potential hazard?
- When was the asset installed/constructed?
- Is the asset still performing as it was intended? (e.g., leaking/cracked pipes)
- Have there been previous historical climate-related hazards observed in the area?
- What is the accessibility of the asset? (e.g., Is it along the road, or on a cross country line without access? Is there enough room for winter snow removal?)
- Is the asset located within the 100 year or 500 year flood zone?
- Have there been new developments that might affect the historical floodplain or potential for flash flooding? (e.g., culverts, new parking lots/increased impervious areas nearby, dams, etc.)
- Is the elevation of the asset above that of the floodplain? Which components would be submerged in a flood scenario (e.g., electrical controls, electrical outlets, equipment, manhole covers, etc.)?
- Are buildings/controls/structures watertight? (e.g., manhole covers, hatches, vents, doors, louvers, electrical feeders, etc.)
- How is the asset connected to electrical utility?
- Is there a standby power source or connection for a portable generator?
- Is there another type of redundancy built into the system?
- What type of telemetry equipment is installed for remote and local alarming?
- Is there convenience lighting in the surrounding area?

- Are there trees or other structures around the asset that might be affected by high winds or heavy rain/snow?

Once the assets have been screened for high, moderate, or low risk from potential climate-related hazard consequences, adaptation or resiliency alternatives are identified and evaluated to address or mitigate the risk in the most cost-effective manner.

Adaptation Measure Evaluation

Using the available climate-related hazard information and the screening-level risk analysis, potential adaptation or resiliency alternatives should be identified that will eliminate or reduce the asset-specific vulnerability. For proposed infrastructure, preference should be given to adaptation measures that would preemptively eliminate potential vulnerability to the climate-related hazards. For example, locating structures away from floodplains, planning for stand-by power sources, including built-in process redundancy, or removing large trees that could pose a blow-down risk to future infrastructure.

If the vulnerability cannot feasibly be eliminated, the remaining adaptation alternatives should instead focus on improving the resiliency to a specific hazard. For example, if it was not technically or economically feasible to construct to relocate a pump station outside of or above the 100-year floodplain, it may be possible to construct/retrofit the existing pump station with flood barriers and elevate critical electrical components to increase flood resiliency.

Adaptation measures can generally be grouped into two major categories: operational and asset-specific measures. Operational adaptation measures are tasks or procedural changes that Town staff could undertake at minimal cost to prevent or mitigate potential hazard consequences. Asset-specific measures may include non-routine or one-time tasks, in-depth studies or evaluations, design modifications, or capital expenditures to achieve the goal of preventing or mitigating the potential hazard consequence.

The following are examples of potential operational adaptation measures to be considered:

- Perform routine inspections of exposed equipment after heavy or intense precipitation events.
- Monitor pump station flow trends during wet-weather events and snow-melt conditions.
- Exercise extreme caution and limit travel time during poor travel conditions.
- Discuss utility power restoration priorities with utility power supply company.
- Exercise caution and use proper PPE while working outdoors in wet-weather conditions.

- Evaluate I/I reduction in the collection system.
- Review wet-weather management plan to ensure it is up-to-date and make any necessary adjustments.
- Review wet-weather management plan with current operations staff and any new hires.
- Routinely remove excess snow to facilitate access to critical assets.
- Monitor large trees adjacent to utility power lines and discuss potential risks with utility power supply company.
- Monitor cross-country sewer lines for signs of ponding on manholes and embedment erosion.
- Develop an emergency pump station access plan and procedures manual with operations staff in case flooding restricts typical access routes to pump station.
- Obtain a small flat bottom boat for deployment if flood waters restrict vehicle access to the pump station site.

The following are examples of asset-specific adaptation measures to be considered:

- Locate sewer and pump station infrastructure outside of or above the flood zones.
- Consider low pressure sewers (versus conventional gravity sewers) inside of flood zones.
- Evaluate and install drainage improvements in areas with significant local flooding or ponding of water on sewer manholes.
- Upgrade pump station buildings to include removable flood barriers at the building entrances and louvers to protect the station’s critical electrical and mechanical equipment from flood damage.
- Upgrade stand-by generators and relocate them 1 to 3 feet above the 100-year flood elevation (depending on criticality) to reduce the risk of flood damage.
- Install portable generator power receptacles and manual transfer switches at pump stations to provide back-up power in the event of an extended utility power or dedicated standby power system failure.

- Install bollards to protect the station structure and equipment from potential damage due to snow removal activities and/or vehicular impacts during inclement weather conditions.
- Discuss expected utility repair crew response time for the pump station area with the local utility power supplier and keep an up-to-date contact list of sewage/septage hauling contractors in the event that bypass pumping is needed.
- If the pump station is upgraded, consider dry-pit submersible pumps that are capable of being fully submerged without damage.
- Evaluate and implement drainage improvements in areas with significant local flooding or ponding of water on sewer manholes.
- Provide adequate access routes to major interceptor sewers to facilitate frequent maintenance, inspection activities, and repairs, as needed.
- Evaluate and implement water-tight manhole covers in low-lying and flood-prone areas, as needed.
- Continue Town's private inflow source detection and removal program and enforce illicit sewer connection ordinance to reduce I/I.
- Frequent cleaning and CCTV inspection of sewer segments suspected of higher Inflow/Infiltration influence and/or clogging and targeted sewer rehabilitation to decrease influence of wet weather on collection system capacity and pumping needs.

The selected climate adaptation measures should be identified during the pre-design phase and then be carried forward through funding, design, construction and operations to maximize the resiliency and reliability of the Town's infrastructure.

Appendix UU

Barnstable CWMP – Preliminary GHG Emissions Review

WRIGHT-PIERCE
Engineering a Better Environment

MEMORANDUM

TO:	Griffin Beaudoin – Town of Barnstable	**DATE:**	10/30/2020
FROM:	Ed Leonard; George Pickard	**PROJECT NO.:**	20157A
SUBJECT:	Barnstable CWMP – Preliminary GHG Emissions Review		

BACKGROUND AND PURPOSE

The Town of Barnstable submitted its Comprehensive Wastewater Management Plan (CWMP) for review under the Massachusetts Environmental Policy Act (MEPA). The Executive Office of Energy and Environmental Affairs (EOEEA) issued a Certificate of the Secretary of the EOEEA on the Expanded Environmental Notification Form (EENF) dated April 3, 2020 which required an evaluation of greenhouse gas (GHG) emissions under the May 5, 2010 GHG Policy. The policy requires project proponents to quantify carbon dioxide emissions and identify measures to avoid, minimize or mitigate such emissions.

The Barnstable CWMP describes a Recommended Plan (significant expansion of traditional wastewater management systems supplemented by non-traditional nitrogen removal measures) and a No Action Plan (continued widespread use of septic systems without expansion of traditional wastewater management systems). The Recommended Plan and the No Action Plan will result in continued and increased long-term electrical energy and fossil fuel use related to septic systems, I/A systems, sewer system conveyance pumping, wastewater treatment, effluent disposal and sludge disposal.

A preliminary evaluation of GHG emissions has been performed for the Recommended Plan, comparing a "project baseline" and a "preferred measures" plan. Design assumptions for the "project baseline" are based on existing operations as well as general requirements for expansion of wastewater management systems according to the requirements of TR-16, *Guides for the Design of Wastewater Treatment Works,* 2016 Edition.

The purpose of this technical memorandum is to summarize the methodology utilized to estimate the "project baseline" condition, to analyze options to achieve GHG emission reductions, to develop a listing of recommended measures and to estimate the GHG emission reductions under this "preferred plan". The content of this memorandum and analysis is based on the material outlined in the CWMP and EENF filing.

DESCRIPTION OF PROJECT BASELINE

The project baseline was formulated in conjunction with the Town based on: the number of septic systems; the number of innovative/alternative (I/A) septic systems; the number of sewer connections; the number and size of sewage pump stations; and the number, size and function of wastewater treatment plants required for the CWMP. This information is summarized in Table 2 at the end of this memorandum.

The pump stations were estimated in three categories:

- Small (50 to 500 gpm, submersible pump station)
- Medium (500 to 1200 gpm, submersible pump station with small electrical building)
- Large (1200 to 7500 gpm, wetwell/drywell pump station with superstructure)

The treatment facility will generally include the following functions/features:

- Preliminary treatment/ headworks and septage receiving
- Primary treatment
- Advanced secondary treatment for nitrogen removal
- Separate stage denitrification filters
- Disinfection
- Effluent pumping and disposal
- Biosolids thickening for off-site disposal
- Standby power system
- Administrative, operations, maintenance and laboratory functions

CALCULATION APPROACH

Since this project is only in the planning phase (i.e. no detailed design information is available), we have utilized engineering judgment and "unit emission rates" for septic systems, I/A systems, pump stations and the treatment facilities based on a literature search. The parameters included and excluded from this analysis are summarized in Table 1 at the end of this memorandum.

Emissions have been categorized as direct or indirect emissions in accordance with the May 5, 2010 MEPA GHG Policy. Direct emissions include on-site stationary sources which burn fossil fuel for heat, hot water, steam and other processes. Indirect emissions result from the consumption of energy, such as electricity generated by burning of fossil fuels, and emissions from vehicles used by employees. Unit emission rates were developed using literature values for emission sources. The basis for the unit emission rates is summarized in Attachment A. These values can be better refined in the design phase.

GHG EMISSION REDUCTION ALTERNATIVES AND SELECTED MEASURES

Numerous concepts were considered to reduce GHG emissions associated with the CWMP. General and specific operating and design practices to improve energy efficiency were aggregated from a literature search. Measures were sorted by system (pump station or treatment facility) and then further organized as "previously suggested" (from 2015 Barnstable WWTP Walk-through Report), operational measures, building system energy conservation measures, system energy conservation measures, and renewable energy measures. These measures are summarized in Table 3 for the pump stations and in Table 4 for the treatment facility.

Each of the identified measures were evaluated for applicability and for the potential to reduce GHG emission for the Barnstable CWMP and were categorized as follows:

- *Preferred Measure* - These items are preferred and recommended for implementation.
- *Not Preferred Measure* - These items are not preferred and not recommended for implementation.
- *Measure to be Considered in Final Design* - These items may be preferred but the analysis requires more details to make an informed decision.
- *Not Applicable* - These items do not meet project goals, project requirements and/or relevant design standards and are not recommended for implementation.

As required by the GHG Emissions Policy, an explanation is provided for any measures that are not preferred. Where available in the literature, a range of energy savings associated with the identified measures is also identified. These values vary considerably and are highly dependent on the application.

Most of the measures provide energy savings to a select portion of the system (e.g., aeration systems, dewatering systems, heating and cooling energy, etc.) and many of the measures have overlapping benefits (e.g., perform facility energy assessment, energy education, specific process improvements, avoid throttling valves, install VFDs, etc.). Engineering judgement was used to assess cumulative energy reductions for the major process systems based on the ranges from the literature search. The direct emissions (resultant from gas burning) portion of the facility energy use was derived using the Barnstable facility's reported natural gas consumption. Estimated energy use reduction was converted to GHG emissions reduction (as CO_2-equivalent) using EPA conversion factors. This preliminary GHG emission estimate may be influenced substantially by process and operations decision made in the design phase.

SUMMARY AND CONCLUSIONS

The MEPA GHG Policy requires that the project proponent evaluate measures to reduce GHG emissions. MEPA requires that the Town commit to implementing the Preferred Measures. The estimated GHG emissions for the Baseline Scenario are 11,280,000 kg CO2-eq/year, as summarized in Table 5 at the end of this memorandum. The estimated GHG emissions for the CWMP with Preferred Measures are 9,060,000 kg CO2-eq/year, as summarized in Table 5 at the end of this memorandum.

The Preferred Measures are estimated to result in a 20% decrease in overall GHG emissions. This is the net result of a 0% change in emissions from septic systems, a 5% decrease in emissions from sewage pumping stations, and a 30% decrease in emissions from centralized wastewater treatment.

Many of the identified measures require more detailed analysis to determine if they meet process objectives in addition to reducing GHG emissions. Additional reductions could result from the "Measures to be Considered in Design"; however, it is premature for the Town to commit to these measures at this time.

TABLE 3 GHG EMISSION REDUCTION MEASURES FOR PUMP STATIONS

	Measure	Small	Medium	Large	
Previously Suggested[1]	Reduce pumping lift station energy usage	P	P	P	Not quantified
Energy Conservation Measures	Install VFDs	NP	NP	P	10-40% of motor HP [a]
	Replace inefficient pumps	P	P	TBC	2-15% of motor HP
	Retrofit with premium efficiency motors	P	P	P	4-8% of motor HP
	Install improved pump controls	P	P	P	1-15% of motor HP [c]
	Evaluate demand, replace with smaller pumps	NP	NP	TBC	Application dependent, detailed design required
	Identify and reduce infiltration/inflow	TBC	TBC	TBC	Monitoring required to quantify.
	Install jockey pump	NA	NA	TBC	Application dependent, detailed design required
	Install power factor correction capacitors	NA	NA	P	5-10% of connected load
	Reduce water consumption	TBC	TBC	TBC	Application dependent, detailed design required
	Reduce pump head by increasing pipe size, decrease roughness	NA	NA	TBC	Application dependent, detailed design required
Building System Energy Conservation Measures	Install timer or motion-detecting lights	NA	P	P	15-90%[a] of lighting energy
	Install high-efficiency lighting	NA	P	P	30%[a] of lighting energy
	Install programmable thermostats	NA	P	P	10%[e] of heating and cooling energy
	Implement increased air ventilation system maintenance	NA	P	P	Application dependent, detailed design required [a]
	Install solar thermal heat system	NA	NP	TBC	Application dependent, detailed design required
	Wastewater heat recovery	NA	NA	TBC	Application dependent, detailed design required
	Use LEED Building practices as guidance with no certifications	NA	TBC	P	14-48% of building energy [a]
Operational Measures	Run at higher wet well levels	TBC	TBC	P	Application dependent, detailed design required [a]
	Set pumps at lower flow rates	NA	TBC	P	Application dependent, detailed design required [a]
	Implement enhanced maintenance program	TBC	TBC	P	May reveal inefficiencies [b]
	Install smart meter energy monitoring system and perform real time energy monitoring and control	NP	NP	P	5-20%[a] of applicable loads
	Energy Education for Facility Personnel	P	P	P	Expected outcomes not quantified
Renewable Energy	Install Solar PV	NA	TBC	TBC	Application dependent, detailed design required

TABLE 4 GHG EMISSION REDUCTION MEASURES FOR TREATMENT FACILITIES

	Measure	Category	Expected Reduction from baseline/Rationale for Rejection
Previously Suggested[1]	Sludge blower actuator valve and controls upgrade custom retrofit	P	10,015 kWh/yr [1]
	Install new high-performance blowers	P	35-39% of blower energy [1]
	Implement a motor operated valve sequence for aeration control	P	2-5% of total aeration energy [1]
	Install individual dissolved oxygen controls in aeration tank cells	P	2% of total aeration energy [1]
	Reduce nighttime dissolved oxygen level	P	1- 1.5% of total aeration energy [1]
	Install high efficiency garage heating system	P	1,982 therms/yr [1]
	Replacement of hot water circulation pumps in Septage Building and Maintenance Garage.	P	10,046 kWh/yr [1]
	Office building lighting upgrade: T8 to LED	P	5,278 kWh/yr [1]
	Lighting controls – Daylighting	P	683 kWh/yr [1]
	Lighting controls – occupancy sensors	P	2,730 kWh/yr [1]
	Improved thermostat controls	P	2,771 kWh + 279 therms [1]
Operational Measures	Perform Facility Energy Assessment	P	10-50%[a] of total facility energy
	Install smart meter energy monitoring system and perform real time energy monitoring and control	P	5-20%[a] of applications where applied
	Energy education for facility personnel	P	Dependent on measures adopted
	Electric peak reduction	TBC	Application dependent, detailed design required
	Idle or Turn off equipment	TBC	Application dependent, detailed design required
	Use automatic control to monitor and control motors	P	Application dependent, detailed design required [a]
	Properly maintain motors	P	Dependent on equipment status[a]
	Reduce pump rates	TBC	Application dependent, detailed design required [a]
	Avoid using throttling valves	P	15-50%[a] of pumping energy where throttling used
Building System Energy Conservation Measures	Install VFD control on air compressors	TBC	Application dependent, detailed design required [a]
	Maintain and adjust boilers and furnaces, perform regular tune-ups	P	2-20%[a] of heating energy
	Upgrade to high-efficiency boilers	P	30-60%[c] of boiler energy
	Reduce air changes during cold temperatures where allowed by code	P	Application dependent, detailed design required
	Install demand-controlled ventilation with heat exchangers to recapture heat from exhaust air	P	Application dependent, detailed design required
	Implement increased air ventilation system maintenance	P	Can be a significant savings depending on existing maintenance routine[a]
	Install high-efficiency lighting	P	30%[a] of lighting energy
	Install timer or motion-detecting lights occupancy sensors	P	15-90%[a] of lighting energy
	Install programmable thermostats	P	10%[e] of heating and cooling energy
	Wastewater heat recovery	TBC	Wastewater temperature data, and existing heating infrastructure evaluation necessary.
	Install green roof(s) or white roof(s)	TBC	Application dependent, detailed design required

	Measure	Category	Expected Reduction from baseline/Rationale for Rejection
	Heat and cool with heat pumps using effluent	TBC	Application dependent, detailed design required
	Use LEED building practices as guidance with no certifications	P	14-48% of building energy
	Implement passive solar strategies by orienting new buildings with larger southern faces, use sunshades, improve building insulation	P	5%-20[d] of building heating and cooling energy dependent on site conditions
	Install High Efficiency Windows	P	9-22%[b] of heating energy depending on single or double paned windows
Energy Conservation Measures - System	Use of VFDs	P	10-40%[a] where applied
	Use of premium efficiency pumps and motors	P	4-8%[a] of pumping energy
	Reduce water consumption	TBC	Water consumption data, operations, and equipment O&M information necessary.
	Increase piping sizes to reduce friction loss	TBC	Equipment operating and existing site specific details required for evaluation.
	Aeration & biological nutrient removal process control, blower, mixer, pumping and diffuser equipment upgrades	P	30-40%[a] of aeration energy
	Sludge dewatering improvements	P	10-30% of sludge dewatering and transport energy
	Continue to process all septage and off-site sludges received as biosolids, only filtrate treated in the liquid treatment process.	P	4% of flow-based treatment energy[2]
	Select supplemental carbon chemicals with lower GHG emission	TBC	Application dependent, detailed design required
Renewable Energy	Install Solar Thermal	TBC	30%[e] of heating energy, Application dependent.
	Install Solar PV	TBC	Currently have solar PV, could expand if space permits
	Install Wind Turbine	TBC	Currently have two wind turbines, could expand if space permits
	Effluent Hydraulic Turbine	NA	Insufficient site topography
	Sludge energy recovery	TBC	Sludge and operating data required.
	Natural gas combined heat and power	TBC	Dependent on sludge energy recovery selection.

Executive Summary

Recharge capacity at the Barnstable Water Pollution Control Facility (BWPCF) is currently limited due to concerns about flooding downgradient of the infiltration beds at low-lying areas, particularly beneath houses adjacent to existing ponds. The current groundwater discharge permit maximum day discharge is 2.7 million gallons per day (MGD). The average monthly discharge ranges from 1.4 MGD to 1.9 MGD based on 2014 through 2018 BWPCF records with an annual average discharge of 1.6 MGD for that period. The Town of Barnstable plans to expand the existing sanitary collection system and treatment plant as part of the Comprehensive Wastewater Management Plan (CWMP). This study includes additional fieldwork to identify the depth and extent of clay beneath the BWPCF, the development of steady-state and transient groundwater models which include this clay and the simulation of five scenarios.

The five scenarios include a transient simulation to identify the seasonal site capacity at the BWPCF based on impacts to off-site groundwater levels (Scenario 1), simulations of travel times to public water supply wells under both transient (Scenario 2) and steady-state conditions (Scenario 3), steady-state simulation of the feasibility of groundwater withdrawals in order to increase the BWPCF site capacity while protecting downgradient areas (Scenarios 4A/4B), and steady-state simulation of the impacts from potential sea level rise (Scenarios 5A/5B).

Findings

The geophysical survey and borings advanced as part of the 2019 site investigation at the BWPCF and the 2019 geophysical survey identified an extensive clay and silt layer under the site. The observed head difference of 6 feet (ft) and lack of response to changes in observed water levels during focused loading at the well beneath the clay/silt indicates that this clay layer limits the vertical flow of groundwater. The depth of the clay/silt layer is variable from 55 to 107 feet below ground surface (ft bgs). Borings outside the BWPCF site suggest the clay is laterally extensive and generally at an elevation of approximately 0 to -40 ft NGVD29.

Effluent recharge capacity is limited primarily by depth to water at low lying areas, particularly near St. Francis Circle. The site effluent recharge capacity varies depending on the amount of recharge from precipitation over the preceding three months. The estimated average annual site effluent recharge capacity is 2 MGD. (Scenario 1) The effluent recharge rate for the BWPCF is currently at or near the simulated effluent recharge capacity during the months of March through June. Figure ES-1 shows the average reported monthly flows and estimated monthly site recharge capacity. The error bars show the range of flows and simulated monthly capacity for the period from 2014 through 2018.

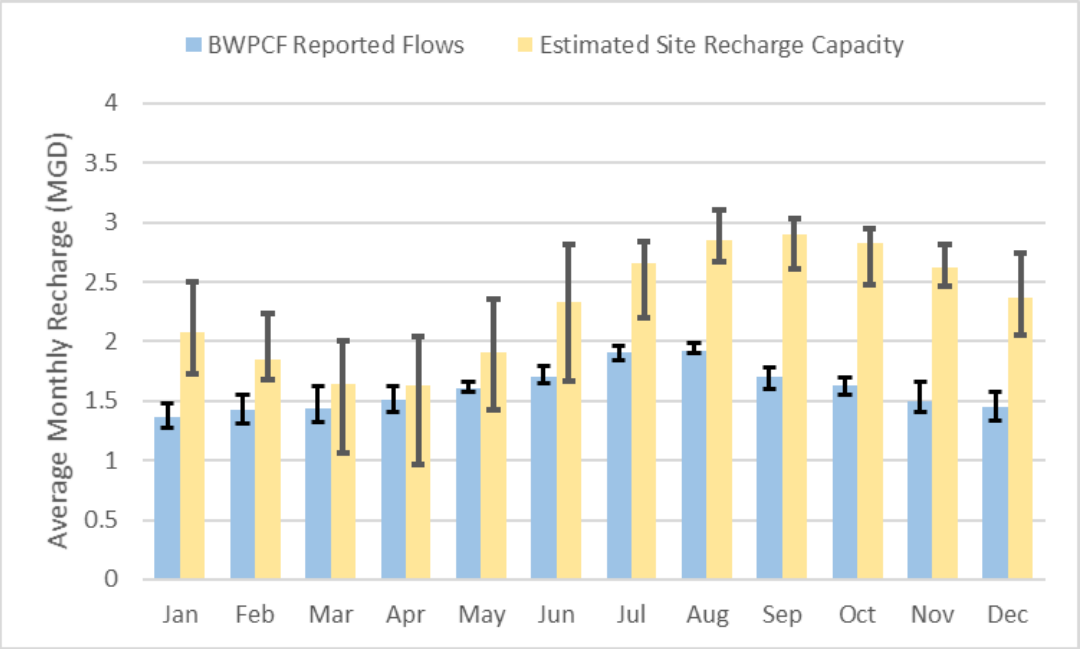

Figure ES-1: BWPCF Reported Flows and Simulated Monthly Capacity from 2014 through 2018

Impacts to public water supply wells are greater than 5 years time of travel both in the transient conditions, based on the last five years of pumping and recharge, and steady-state conditions, with the higher seasonal capacity and permitted pumping rates at nearby wells. (Scenarios 2 and 3)

Withdrawal of water can reduce groundwater levels to acceptable levels off-site, however, nearly all water above the site capacity needs to be withdrawn. The feasibility of focused groundwater withdrawals was simulated using steady-state scenarios and should be reviewed in a transient simulation due to the 3-month lag in the water table in response to changes in recharge. The simulation assumes that any water withdrawals will be discharged to the aquifer far enough from the site to prevent impacts to the water table. (Scenarios 4A and 4B)

In addition to coastal inundation, a sea level rise of 2-ft will increase the baseline groundwater elevations at the site by approximately 0.8 ft (USGS 2016). The simulations of sea level rise assumed increased pumping at public water supply wells at nearly four times the current pumping rates. Because of this increased pumping, steady-state simulations based on the estimated site recharge capacity of 2 MGD did not show increases in the water table beneath structures. (Scenario 5A). The steady-state simulation of build-out conditions with a recharge rate of 6 MGD (Scenario 5B) showed areas with groundwater depth of less than 8 feet near St. Francis Circle, Barnstable High School, Enterprise Road/Cape Cod Mall and near Fawcetts Pond.

Recommendations

Based on the findings of this study, the following recommendations are being made:

- Use focused loading data and detailed depth to clay information to fine tune the model beneath the site and optimize bed loading. The elevation of the layer beneath beds 40 to 48 is high and it may be possible to take these beds off-line to allow for treatment plant expansion, if needed.
- Collect water level data at St. Francis Circle to evaluate the response to site loading rates, precipitation and background groundwater levels. An off-site sentinel well which is not impacted by the BWPCF should be monitored to provide information on aquifer response to recharge from precipitation.
- Develop a predictive tool based on water levels in sentinel and downgradient wells, recorded precipitation and climate data (temperature) to estimate the actual recharge in the prior 3 months and predict monthly site capacity.
- Optimize placement and pumping rates for focused feasibility withdrawals with steady-state and transient modeling. Determine the seasonal impacts to pumping withdrawals using the transient model and simulate the impacts from recharge of withdrawn water.
- Identify secondary loading sites for potential wastewater recharge. Evaluate the impact of recharge at the secondary loading sites including the additive impacts from the mounding due to the BWPCF recharge beds.
- Verify well depths and conduct downhole geophysics to identify clay layers at selected locations where data was unclear.
- Improve the simulation of lakes and ponds, particularly Wequaquet Lake, in the groundwater model using the Lake Package in MODFLOW. This will allow for simulation of the resistance of lake bed sediments to flow and simulation of water levels based on lake and pond bathymetry.
- The risks of increased effluent discharge at the BWPCF should be quantified.
- The groundwater flow model should be utilized to determine impacts to groundwater of potential effluent recharge sites.

Section 1
Introduction

Recharge capacity at the Barnstable Water Pollution Control Facility (BWPCF), shown on **Figure 1,** is currently limited due to concerns about flooding downgradient of the infiltration beds at low-lying areas, particularly existing ponds. The current groundwater discharge permit maximum day flow capacity is 2.7 MGD. The average monthly discharge flow ranges from 1.4 MGD to 1.9 MGD based on 2014 through 2018 BWPCF records with an annual average discharge flow of 1.6 MGD for that period. The Town of Barnstable plans to expand the existing sanitary collection system and treatment plant as part of their Comprehensive Wastewater Management Plan (CWMP) program. This study includes additional fieldwork to identify the depth and extent of clay beneath the BWPCF, development and calibration of steady-state and transient groundwater models which include this clay and simulations of five scenarios.

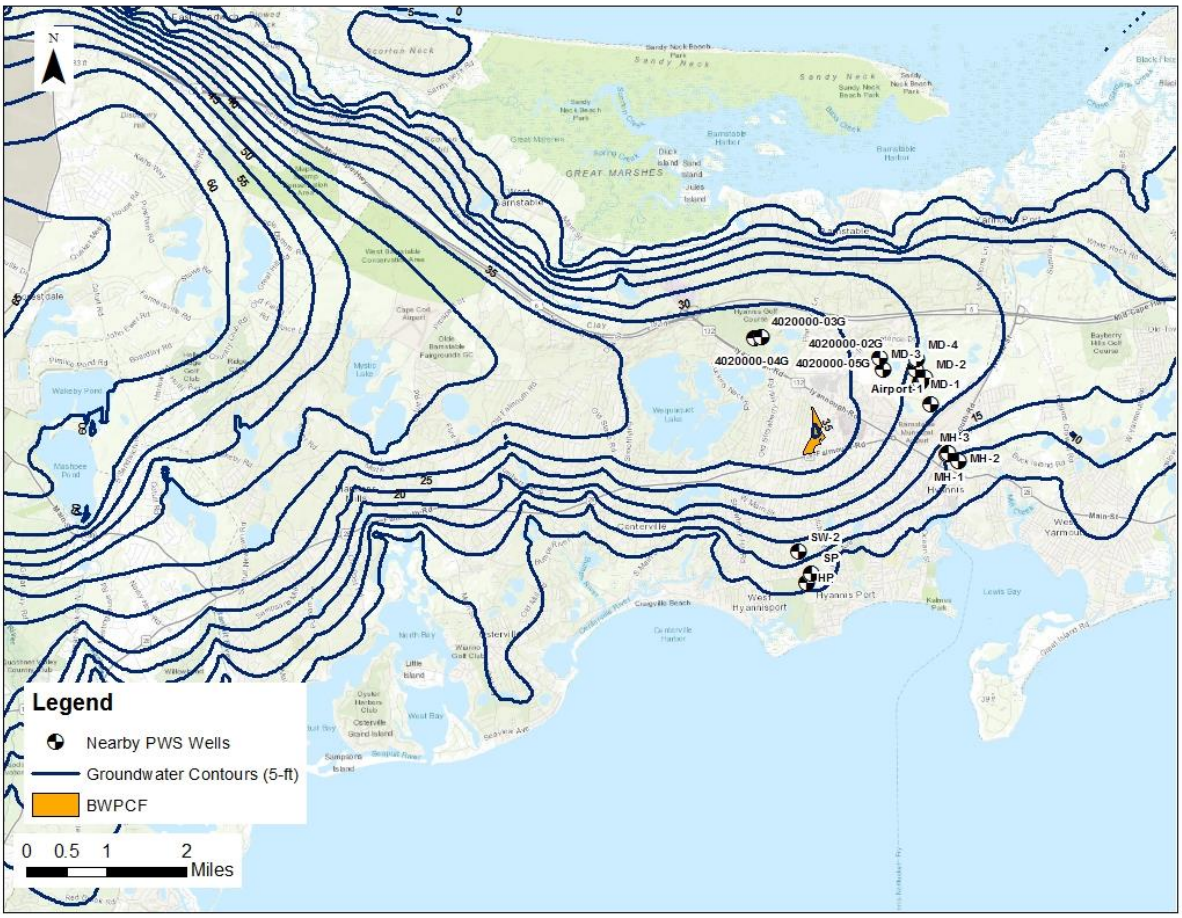

Figure 1: BWPCF Location and Regional Groundwater Contours

The five scenarios include a transient simulation to identify the seasonal site capacity at the BWPCF based on impacts to off-site groundwater levels (Scenario 1), travel times to public water supply wells under both transient (Scenario 2) and steady-state conditions (Scenario 3), the feasibility of withdrawals in order to increase the BWPCF site capacity while protecting downgradient areas (Scenarios 4A/4B), and the impacts from potential sea level rise (Scenarios 5A/5B).

Groundwater levels in Barnstable fluctuate several feet during a year due to changes in monthly recharge from precipitation and septic and wastewater return flows. Recharge is highest in the winter and spring and lowest in the summer and fall. Average groundwater levels also fluctuate several feet from year to year. Depth to groundwater measurements taken between 1976 and 2019 at Well MA-A1W 306, located at the Barnstable High School, have a range of almost 8 feet from 20.8 feet below ground surface (ft bgs) in 1998 to 28.5 ft bgs in 2002. Water levels are highest in late spring (April, May and June).

Due to the seasonal population in Barnstable, wastewater flows are highest during the summer and lowest during the winter. The BWPCF currently has issues with discharge capacity during high water periods in late spring and during extended wet periods, such as in the summer of 2018. The transient groundwater model developed for this study allows for estimation of the seasonal capacity of the BWPCF using the period from 2014 through 2018 which includes both wet and dry periods.

Section 2
Field Work

The hydrogeology of the BWPCF site has been extensively studied (Maravell et al., 1984; Cambareri, 1986; Geraghty and Miller, 1995; Stearns and Wheler, 2003; Stearns and Wheler, 2005; Stearns and Wheler, 2011; Watershed Hydrologic, Inc., 2014; GHD, 2017). Existing data was reviewed to identify data gaps. Based on the data review, a field program was developed and implemented that included boring and well installation, geophysical surveys, slug testing and focused loading at the recharge beds. The information gathered as part of the field work investigation, as well as an evaluation of prior reports, were used to refine the site conceptual model and update the numerical groundwater flow model.

2.1 Existing Data

Several sources of existing data were utilized to help refine and calibrate the model near the BWPCF. These sources included publicly available well and water level data from the Massachusetts Department of Environmental Protection (MassDEP) and the United States Geological Survey (USGS), as well as site-specific data from previous studies conducted near BWPCF. Existing data was imported along with the new data collected from the field program to a three-dimensional visualization and analysis (3DVA) model in Leapfrog Works. The 3DVA model was used to estimate the depth and lateral extent of clay beneath the site based on existing boring logs and cross-sections from previous studies.

2.1.1 DEP Well database

MassDEP maintains a web-based database of groundwater wells in Massachusetts for use by the well drilling industry, local, state, and Federal governments, and the general public. Groundwater well information including location, completion date, well type, total depth, and measured water level was downloaded from the Energy and Environmental Affairs (EEA) Data Portal for all documented wells located in Barnstable (EEA 2019). Well drilling logs were also downloaded for wells located near BWPCF, if available. A total of 1,777 wells were identified in Barnstable through the EEA Data Portal **(Figure 2**)**.** Not all wells in the database have boring logs accessible online and the quality of the boring log information varies. Of the wells near the site, a total of 127 well logs were considered suitable for the study and were included in the 3DVA model. The remaining wells were not included in the model due to missing or poor quality data.

The USGS also maintains a web-based database of groundwater wells through the National Water Information System (NWIS 2019). A total of 170 wells were identified in NWIS near BWPCF, 119 of which had lithology logs available. Lithology logs were downloaded, digitized, and reviewed, with a focus on the presence or absence of a clay lens.

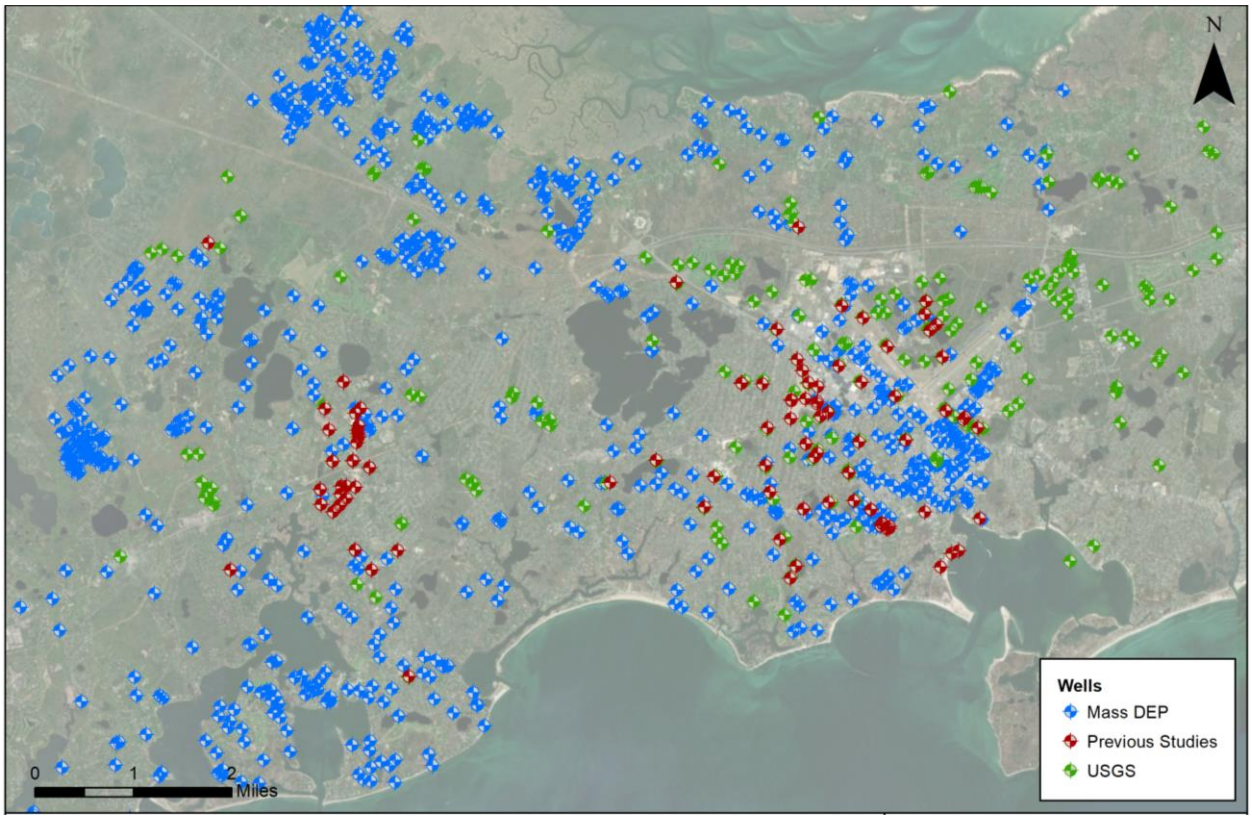

Figure 2: Existing Well Locations – Barnstable

2.1.2 Previous Studies

Extensive work has been conducted by the USGS on the hydrogeology of Cape Cod. This includes development and application of regional numerical groundwater flow models documented in multiple USGS reports including the most recent reports Walter and Whealan 2004, Carlson et al 2015 and Walter et al 2016. In particular, USGS regional cross-sections D-D' and I-I' from Masterson and Barlow 1997, shown on **Figure 3** in green, provided regional interpretations of the geology for the area, which were used in the development of the numerical groundwater model. These cross-sections are provided in Appendix G as part of the 3d visualization.

Previous locally-focused studies and investigations near BWPCF were also reviewed to refine the conceptual model near the site. Wherever possible, cross sections and well data including lithologic logs, well screen intervals, and water level measurements were digitized and imported to the 3DVA model. The following reports were reviewed in this regard:

- Maravell, W., Cambareri, T., Lambert, F., & Campo, J. (1984). *Evaluation of Monitoring Well Data for the Town of Barnstable, Mass Wastewater Treatment Facility.*
- Cambareri, T. C. (1986, September). *Hydrogeology and Hydrogeochemistry of a Sewage Effluent Plume in the Barnstable Outwash of the Cape Cod Aquifer Hyannis, Massachusetts* (Master's thesis). University of Massachusetts, Department of Geology and Geography.

- Geraghty and Miller (1995). *Modeling Analysis to Evaluate Capacity of Groundwater System at WPCF to Accept Treated Wastewater Discharge.*
- Stearns and Wheler (2003). *Effluent Mitigation Investigation Project Task 2 - Groundwater Elevation Monitoring Program.*
- Stearns and Wheler (2005). *Effluent Mitigation Investigation Project Task 3 - Benchmark Evaluation.*
- Stearns and Wheler (2011). *Final Needs Assessment Report Volume 1 – Comprehensive Wastewater Management Planning Project for the Town of Barnstable.*
- Watershed Hydrogeologic, Inc. (2014). *Technical Memorandum No. 1 Town of Barnstable Groundwater Model Development – A watershed hydrogeologic groundwater model.*
- GHD (2017). *Nutrient Management Plan and Additional Services Hyannis WPCF Groundwater Modeling Results Town of Barnstable, MA.*

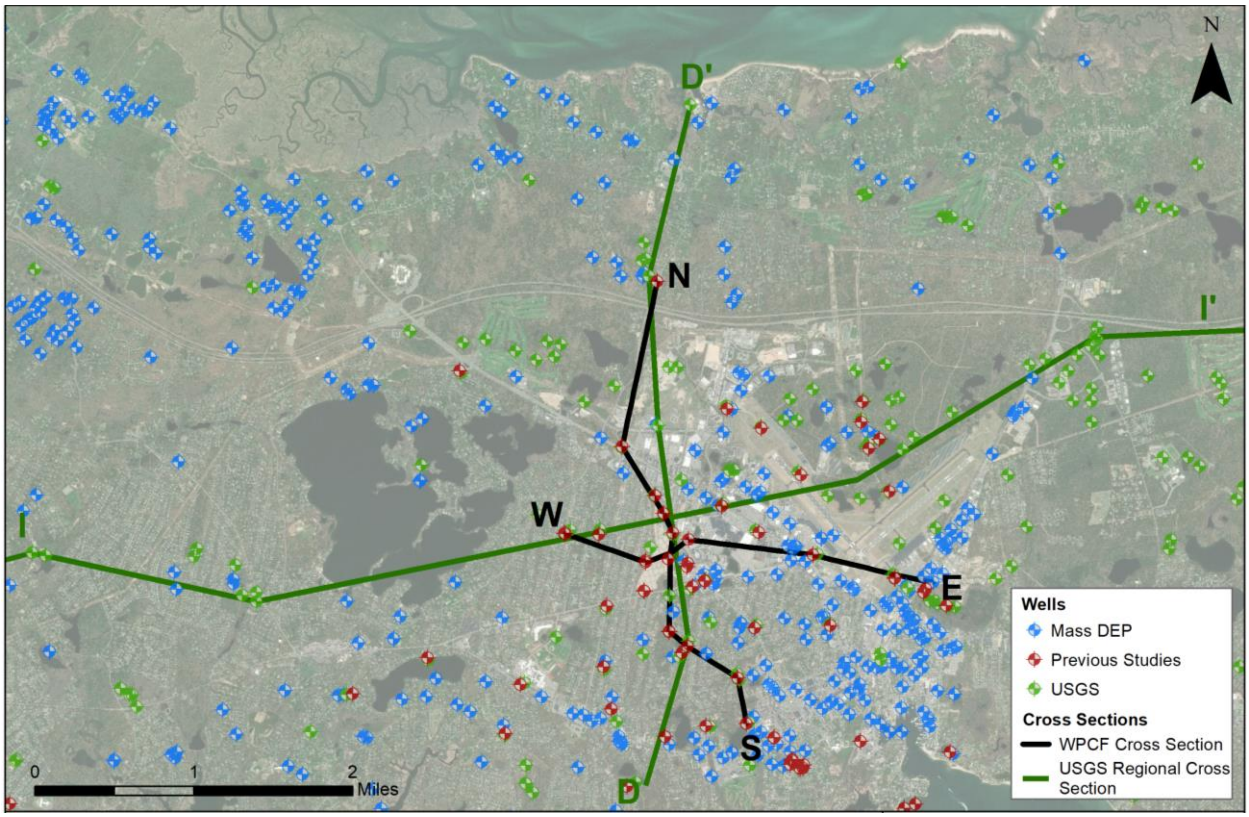

Figure 3: Cross Section Locations from Previous Studies near BWPCF

2.1.3 Site Water Levels

Groundwater levels are routinely monitored at 17 wells by the BWPCF. Water level records at these wells date as early as 1987, and monthly data is available at most wells starting in 2000. Water level data for from the past five and a half years (January 2014 to August 2019) was used to calibrate the model. A map of well locations can be found on **Figure 4** and a summary of well data can be found in **Table 1.**

Figure 4: BWPCF Site Wells

Table 1: Site Wells, Period of Record and Water Level Elevation Ranges

Well	Well Depth (ft bgs)	Start of Record	End of Record	Count	Ground Surface Elevation (ft NGVD29)	Minimum Water Level (ft NGVD29)	Maximum Water Level (ft NGVD29)	Average Water Level (ft NGVD29)	Water Level Range (ft)

2.1.4 USGS water levels

Water level data from the USGS was used to help calibrate both the steady-state and transient models. A total of 570 wells and 31 surface water monitoring locations across Cape Cod were referenced for the steady state model calibration. For the transient model, water level measurements at MA-A1W 306, located southwest of the BWPCF near the Barnstable High School were used in addition to the historical data collected at and near the site by the BWPCF. The water level data recorded during the past five years at MA-A1W 306 are shown in **Figure 5.** Water levels vary between 3 and 5 feet in a year and were high in 2017 and 2018 compared to previous years.

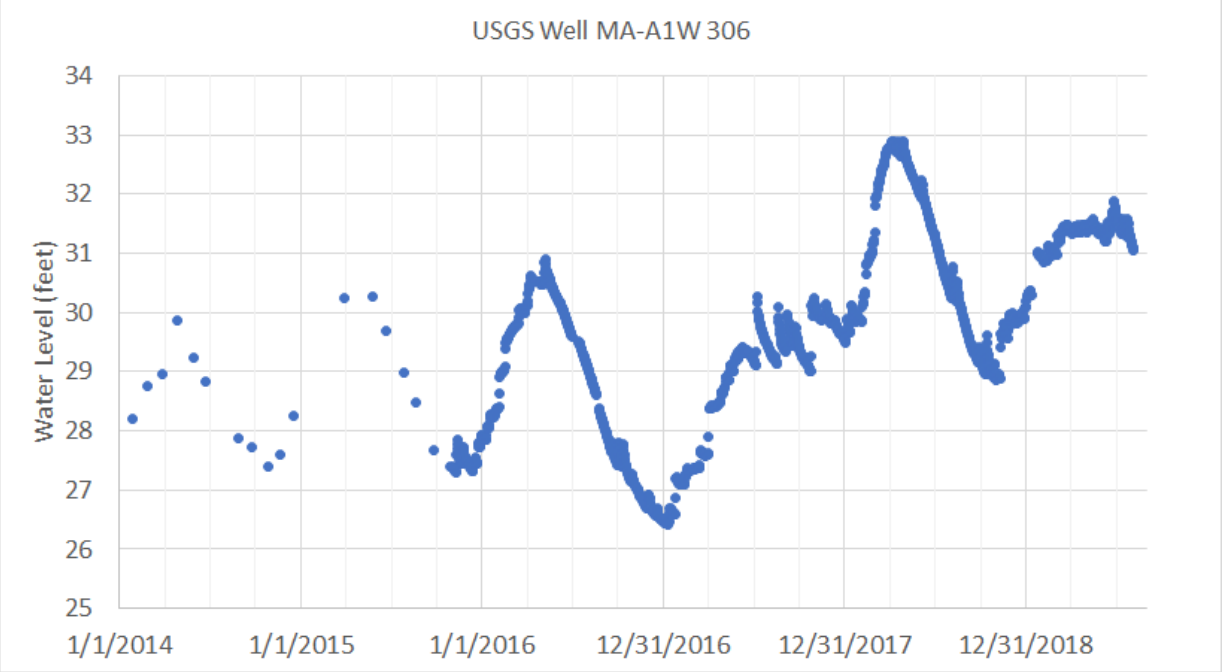

Figure 5: Water Levels at USGS Well MA-A1W 306

2.1.5 BWPCF Bed Loading

Treated effluent at BWPCF is discharged at 49 sand beds where it infiltrates and recharges the groundwater. A schematic diagram of the bed locations is shown in **Figure 6**. Beds 41 and 43 have been removed and beds 2 through 10 are no longer operational due to the installation of solar panels. Beds 33 and 34 are no longer operational due to installation of wind turbines. BWPCF keeps a daily record of which bed(s) receive effluent for infiltration. Influent BWPCF flow and bed use data from BWPCF was used to calculate a timeseries of discharge to each bed for the model period from 2014 through 2019. The monthly average, minimum, and maximum flow for all beds for this period is shown in **Figure 7.** Monthly flows are highest in July and August and lowest in the winter months. The average annual discharge to the beds over the last 5 years was 1.6 MGD, ranging from a minimum daily flow of 0.9 MGD on 1/24/2015 to a maximum daily flow of 2.5 MGD on 7/7/2017.

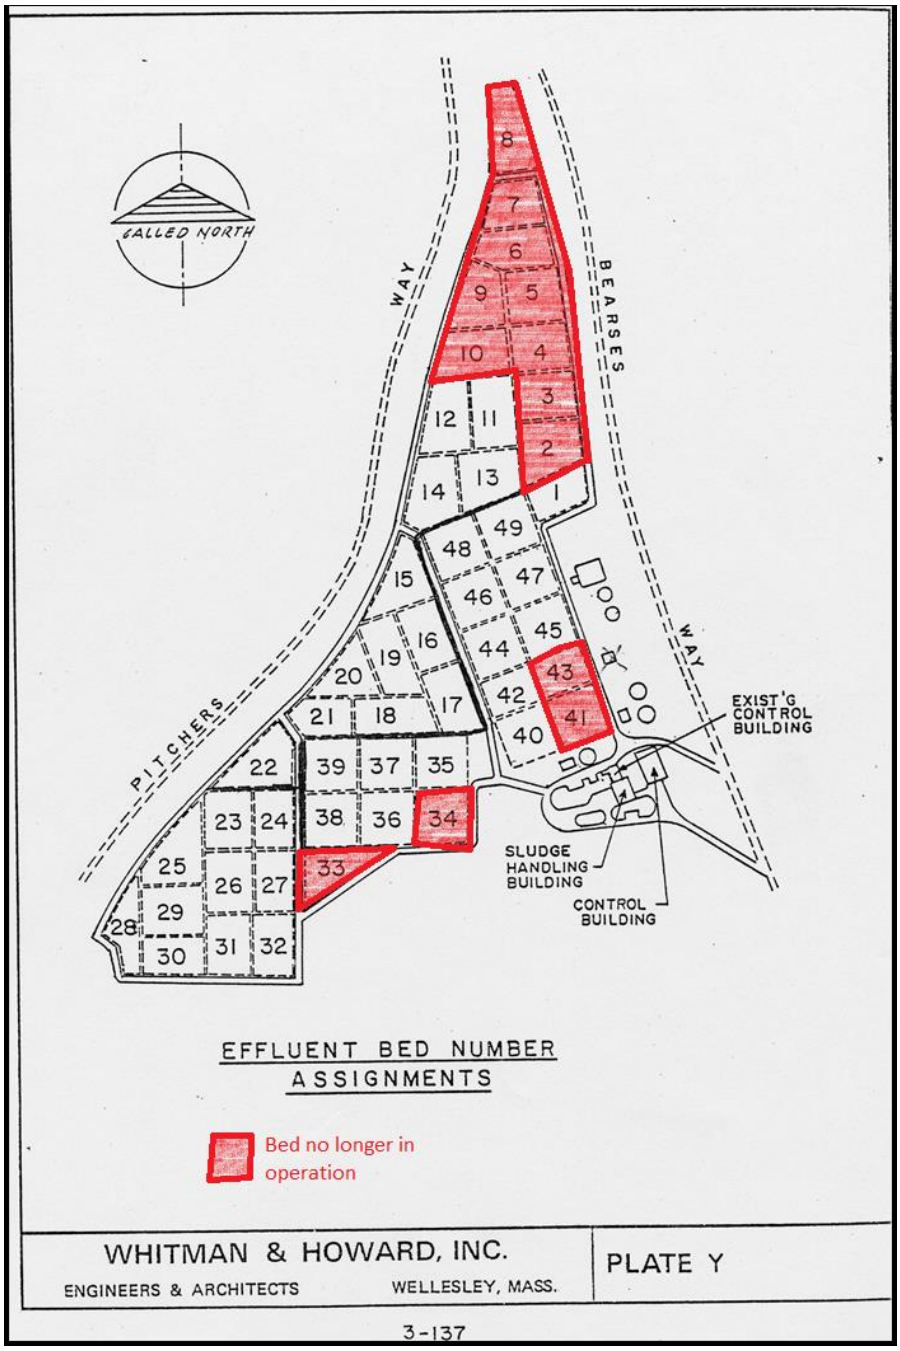

Figure 6: BWPCF Bed Locations and Numbers

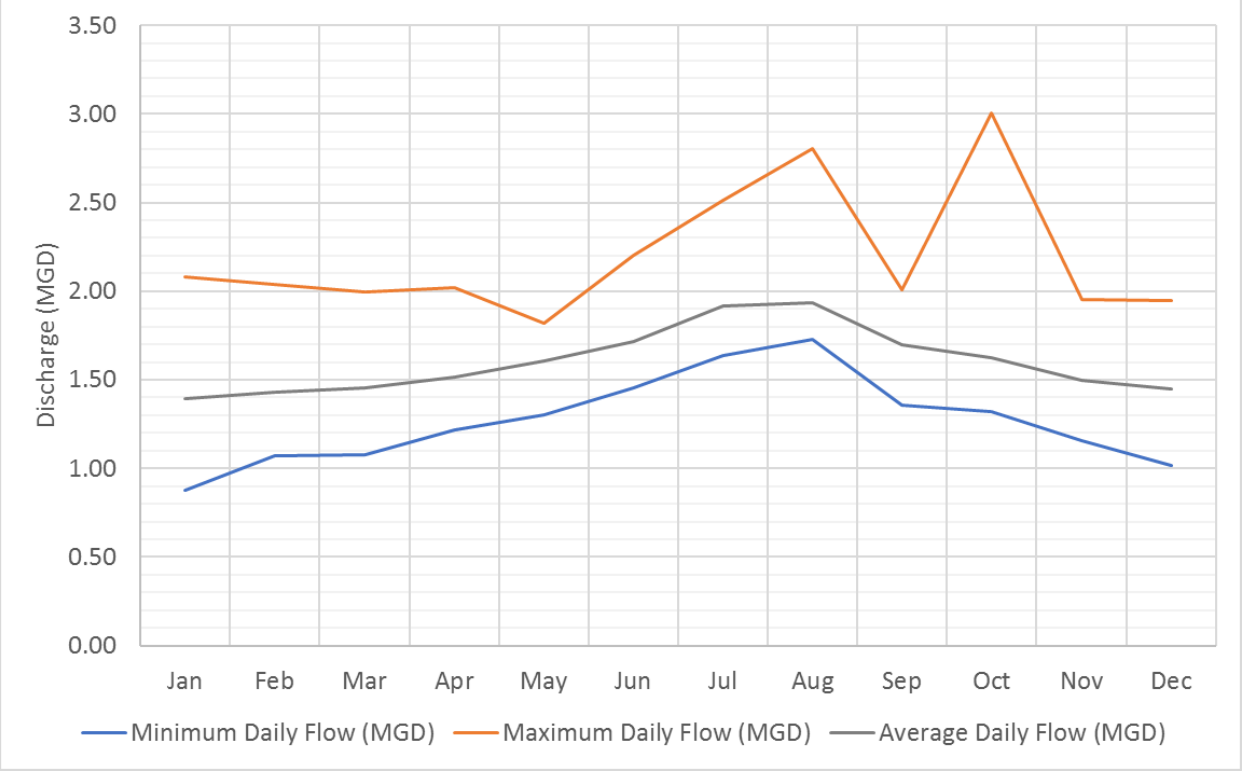

Figure 7: Average, Minimum, and Maximum Daily Discharge at BWPCF (January 2014 – August 2019)

2.2 Boring and Well Installation

Two soil borings were advanced at the site to provide reference data for the geophysics survey, to identify the depth to the clay/silt layer, and to assess the clay/silt layer thickness. Wells were installed at one location (19-01) above and below the clay/silt layer to provide information on the vertical gradient across the clay/silt layer and the thickness of that unit. **Figure 8** shows the location of the borings, wells and geophysics transects.

The location of boring 19-01 was planned in the southwest corner of the recharge beds to provide information on the clay/silt layer. The boring was advanced to a depth of 100 ft bgs (elevation -36 ft NGVD29) in order to determine the top, bottom and thickness of the clay. Boring 19-02 was located in the southeast corner near an existing pond and parking lot. This parking lot regularly floods during wet periods and water levels rise when recharge is applied to beds 40 through 49. Boring 19-02 was selected to investigate the shallow subsurface in this location and identify the possible presence of shallow clay or silt layers and was advanced to a depth of 65 ft bgs (elevation -27 ft NGVD29).

The location and ground surface elevation were surveyed for each of the boring locations and the top of the PVC casing for new wells. Boring logs, well installation reports, and particle size distribution reports for selected soil intervals are included in **Appendix A.** Survey data and a map of surveyed locations are included in **Appendix B.**

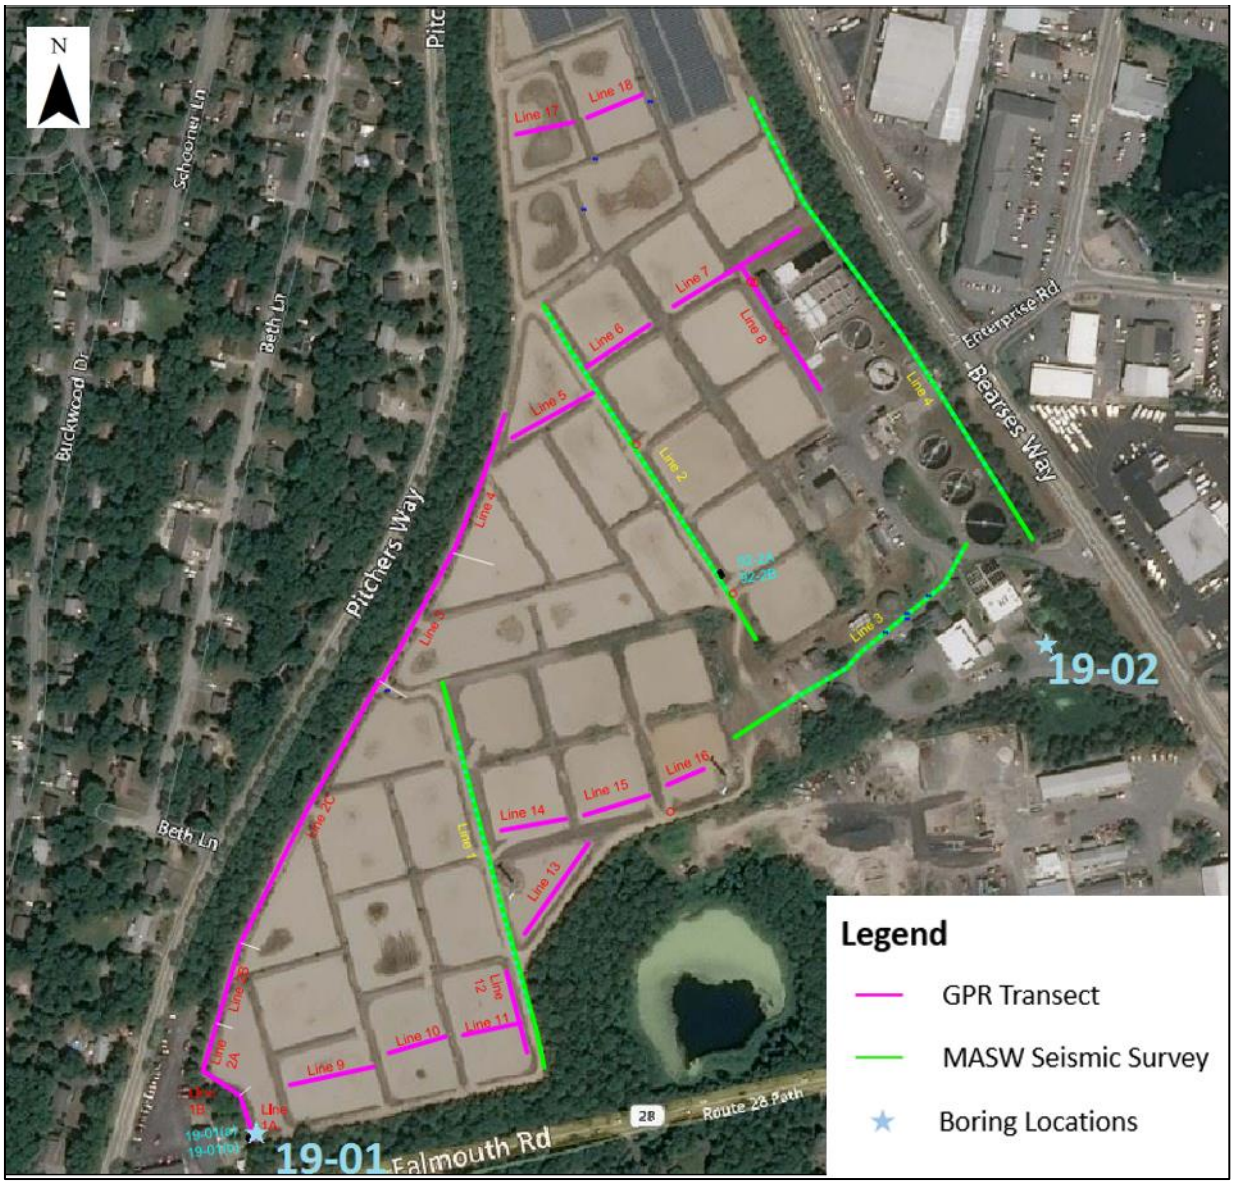

Figure 8: Boring and New Well Locations, Geophysics Transects

The boring at 19-01 was advanced to 101 ft bgs with split spoon sampling every 5 ft and continuous sampling within and below the clay. The geologic deposits encountered consisted of the following:

- light brown, coarse-fine SAND with some-little gravel down to 60 ft bgs
- light brown, medium-fine SAND from 60-78 ft bgs
- light grey, CLAY and SILT from 78-88 ft bgs
- light grey, fine SAND and SILT from 88-89 ft bgs
- light grey-light brown, medium-fine SAND from 89-100 ft bgs

Figure 9 shows photographs of two intervals from boring 19-01. The first shows the coarse-fine sand from 38 to 40 ft bgs. This sand was present in the top 60 feet at the boring. The second photograph shows a 2-foot sample of the clay/silt layer from 78 to 80 ft bgs. This clay/silt layer is 10 feet thick at the boring location.

Two wells were installed at the 19-01, one above and one below the clay/silt layer. A shallow well, 19-01A, was screened from 35 to 45 ft bgs in the coarse-fine sand and a deep well, 19-01B, was screened below the clay/silt layer from 91 to 101 ft bgs. The initial depth to water was 36.8 ft bgs in well screen 19-01A and 30.75 ft bgs in well screen 19-01B. The initial head difference between the two well screens was 6.05 ft, indicating that the clay is a barrier to flow.

Figure 9: Coarse-fine Sand from 38 to 40 ft bgs and Clay/Silt from 78 to 80 ft bgs in Boring 19-01

The boring at 19-02 was advanced to 65 ft bgs with split spoon sampling every 5 feet. The initial depth to water was approximately 3 feet. A well screen was not installed at this location. The geologic deposits encountered consisted of the following;

- light brown, coarse-fine SAND with little-trace fine gravel down to 43 ft bgs
- light brown, medium-fine SAND from 44-53 ft bgs
- light grey, fine SAND, some silt from 53-63 ft bgs
- light grey, fine SAND, SILT, CLAY from 63-65 ft bgs

Grain size analysis was conducted on samples from 3 intervals collected from boring 19-01, shown in **Table 2**. Particle size distribution reports for all three intervals are provided in **Appendix A.** The grain size data from the sample from 35 to 45 feet was used to estimate hydraulic K using three methods, Hazen, Beyer and Wang et al. (AQTESOLV, 2019). The hydraulic conductivity (K) for the coarse sand based on the three estimation methods varies from 126 feet per day (ft/day) to 488 ft/day.

Table 2: Grain Size Analyses for Selected Intervals

Sample		19-01 35-45 ft bgs	19-01 78-85 ft bgs	19-01 91-100 ft bgs
Description	-	light brown poorly graded sand with gravel	gray lean clay	gray-brown silty sand
Grain size, D10	mm	0.2677	< 0.0013	0.0414
Grain size, D60	mm	0.9906	0.0092	0.2189
Grain size, D90	mm	9.6910	0.0280	0.5022
Estimation Method*		**Estimated Hydraulic K**		
Hazen	ft/day	203	not calculated*	not calculated*
Beyer	ft/day	488	not calculated*	not calculated*
Wang et al.	ft/day	126	not calculated*	not calculated*

AQTESOLV 2019

*Hydraulic conductivity was not calculated for deeper intervals at 19-01 because the estimation methods are not valid for the range of particle sizes measured.

2.3 Slug Testing

Falling head and rising head slug tests were performed to provide the basis for estimating horizontal hydraulic conductivity. The tests were conducted using a 2-inch mechanical slug at eight wells throughout the BWPCF property and nearby areas, shown on **Figure 10**. The change in water levels resulting from the insertion and removal of the mechanical slug during the tests was measured using submerged pressure transducers. An example of the change in water levels during slug testing in monitoring well 92-2B is shown in **Figure 11**.

Figure 10: 2019 Slug Testing Locations

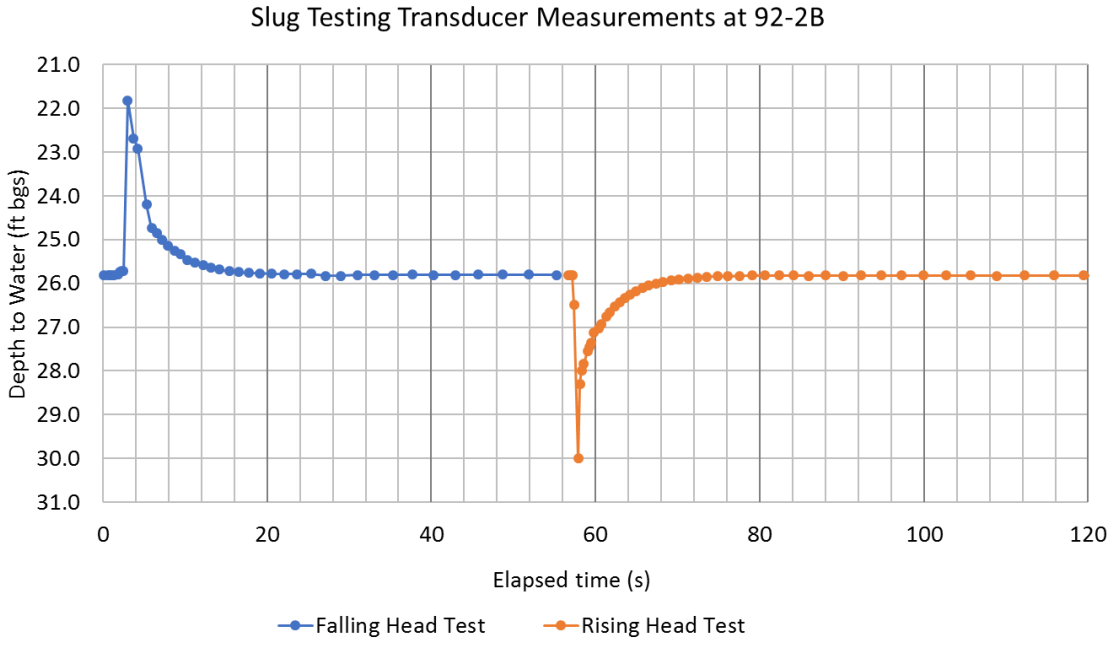

Figure 11: Depth to Water Measurements in Monitoring Well 92-2B During Slug Testing

After insertion of the mechanical slug, water levels quickly rise and "fall" back to the static water level, as exhibited in the "Falling Head Test" depth to water measurements shown in blue. When the slug is removed, the depth to water immediately drops and rises back to static water level, shown in orange on the plot. The responses to the insertion and removal of the mechanical slug occurred over a period of less than 20 seconds, indicating high hydraulic conductivity of the soils immediately surrounding the well screen.

The local hydraulic conductivity was estimated from the water level displacement using the AQTESOLV software package (Duffield, 2007). Several analytical solution methods were used to interpret the data, including the Bouwer-Rice solution (Bouwer and Rice, 1976) for unconfined aquifers and the Springer-Gelhar solution (Springer and Gelhar, 1991) for unconfined aquifers with oscillatory response (which usually occurs in aquifers with high hydraulic conductivity). An example analysis at monitoring well 19-01A is shown in **Figure 12.**

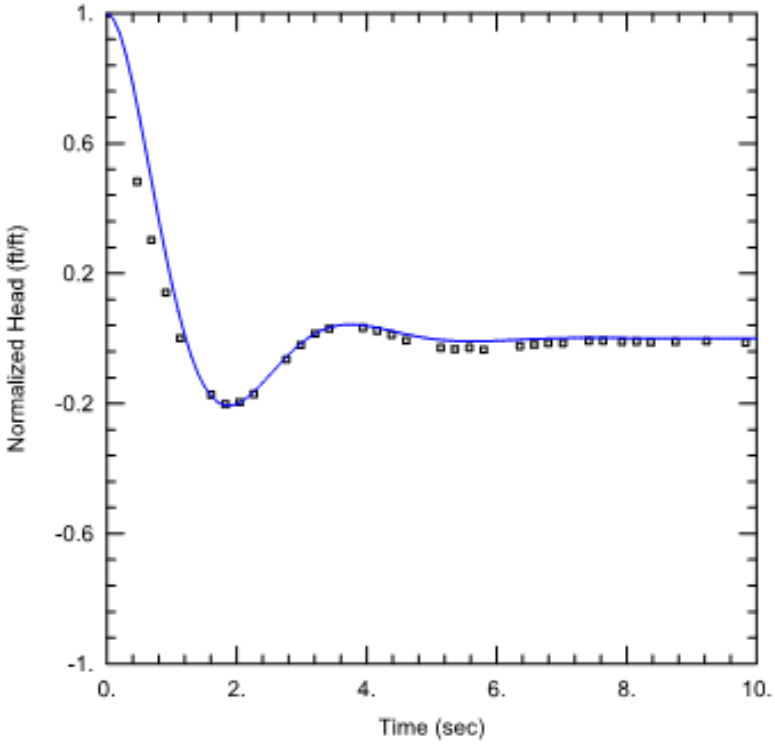

Figure 12: Rising Head Test for Well 19-01A

The observed water levels converted to normalized head in feet/feet (ft/ft) during the test are shown with the black hollow squares and the blue solid line shows the analytical solution that matches the observed data. The example in Figure 12 shows an oscillatory response, when the water level rose above the static water level after the mechanical slug removal and then dropped to the static water level after a second oscillation. The hydraulic conductivity from this analysis was 300 ft/day, which is consistent with the observed oscillatory response. The hydraulic conductivity values estimated from all slug tests ranged from 2 to 1,491 ft/day, as presented in **Table 3**.

Table 3: Hydraulic Conductivity Estimates from Slug Test Analyses

Well	Aquifer Thickness (ft bgs)	Hydraulic Conductivity, K (ft/day)	
		Minimum	Maximum
19-01A	45*	299	1,491
19-01B	> 10 *	2	30
92-16	60	308	333
92-2A	65	616	914
92-2B	80	99	103
92-4	70	504	517
C-2	40*	345	485
W-4	70	340	454

* Aquifer thickness was based on the extent of the well boring for the purpose of the analysis and may be deeper than the value reported in the table.

Most wells exhibited rapid water level responses after the insertion and removal of the slug similar to the example at 19-01A shown in **Figure 12**, indicating high permeability of the surrounding soils.

The hydraulic conductivity values estimated at 19-01B and 92-2B were lower than those estimated from the other tested wells, which was expected from subsurface soils based on boring log at the two locations. The boring log at 19-01B indicated that the screen was set in a dense sand below a local clay/silt layer. The boring log at 92-2B indicated that the screen is located within a section of finer-grained sands. The AQTESOLV results for all tests are provided in **Appendix C.**

2.4 Focused Loading and Water Level Recorders

Focused loading tests were conducted in June and July 2019 to observe the aquifer response to spatial changes in loading application. Eight rounds of testing were conducted for a period of seven days each, during which the wastewater discharge was loaded only to the beds in the focused groups. The infiltration beds were grouped into six groupings that were loaded at least once during the testing period. Submerged pressure transducers were installed prior to the start of testing to record the changes in water levels at selected monitoring wells throughout the BWPCF.

The pressure transducer installed at 92-4 and 19-01A between the dates of June 28, 2019 and July 11, 2019 was corrected for atmospheric pressure after review of the data indicated that the cable venting, which usually removes the impacts of atmospheric pressure changes from the pressure readings recorded by the transducer, was not working properly. The transducer was removed on July 11, 2019 and replaced with a transducer and cable which automatically corrected for changes in atmospheric pressure.

The loading groups are shown in the color-coded polygons in **Figure 13.** The location of the monitoring wells that the pressure transducers were installed in during testing are shown in the green circles.

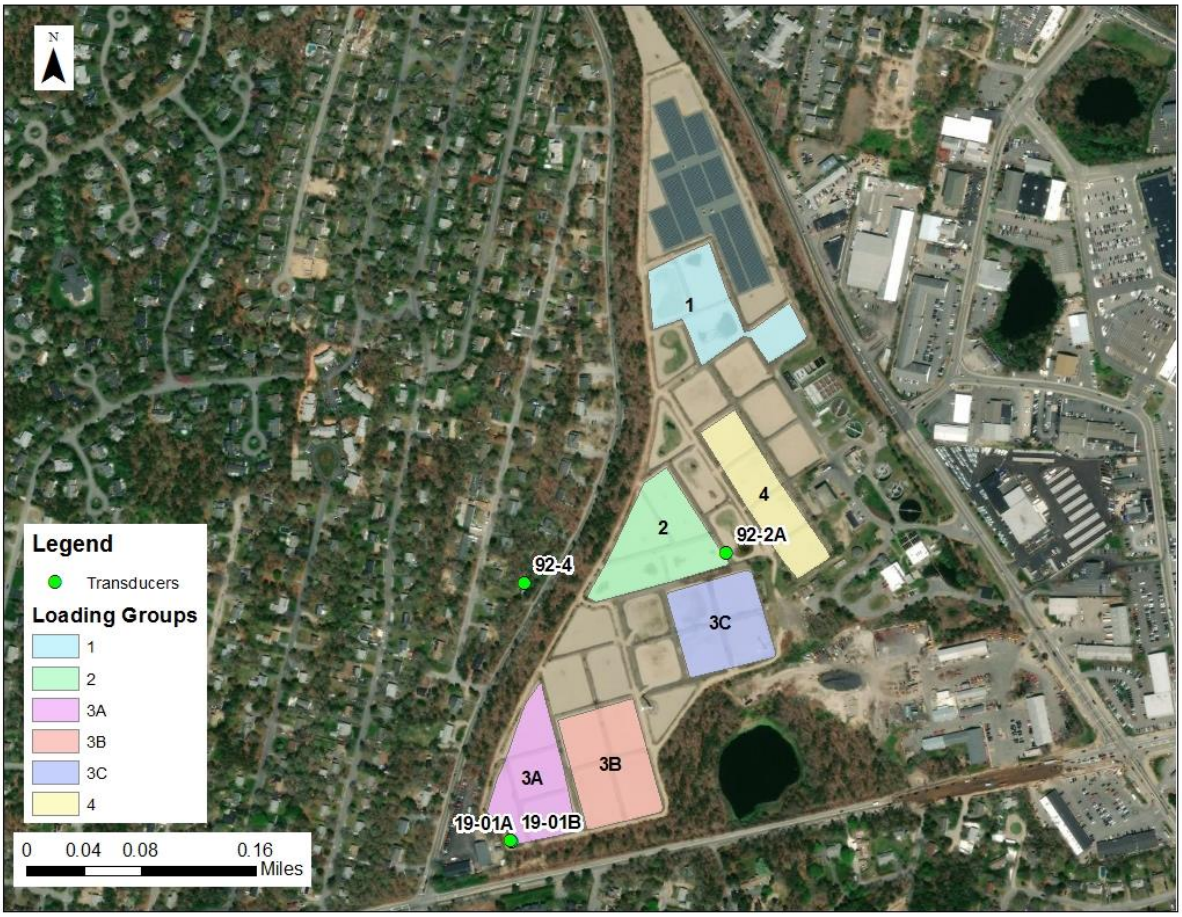

Figure 13: Focused Loading Bed Groupings and Transducer Locations

The loading groups were selected based on the ease of operation (clusters of beds that are located on the same distribution lines) and proximity to monitoring wells (new and existing). The loading groups were also selected to provide a good spatial representation of the BWPCF. The schedule for focused loading is presented in **Table 4.**

Table 4: Table of Focused Loading Test Groups, Including Average Daily Recharge and Bed Locations

Start Date	Group	Beds	Average Discharge (MGD)	Transducer Locations	
6/3	2	18, 19, 20, 21	1.8	92-4	92-2A
6/10	3A	25, 28, 29 30	1.9	92-4	92-2A
6/17	1	1, 11, 12, 13	1.8	92-4	92-2A
6/24	3C	34, 35, 36, 37	1.9	92-4	92-2A
7/1	4	25, 28, 29 30	2.0	19-01A	92-2A
7/8	3C	34, 35, 36, 37	1.9	19-01A	19-01B
7/15	3B	40, 42, 44, 46	2.0	19-01A	19-01B
7/22	3C	26, 27, 31, 32	2.1	19-01A	19-01B

As shown in **Table 4,** each loading group was tested for at least one 7-day period. The loading rate was fairly consistent throughout testing, ranging from 1.8 to 2.1 million gallons per day (MGD). The water levels recorded by the transducers are provided on **Figure 14,** along with the precipitation measured at the Barnstable Airport Weather Station and reported BWPCF flows.

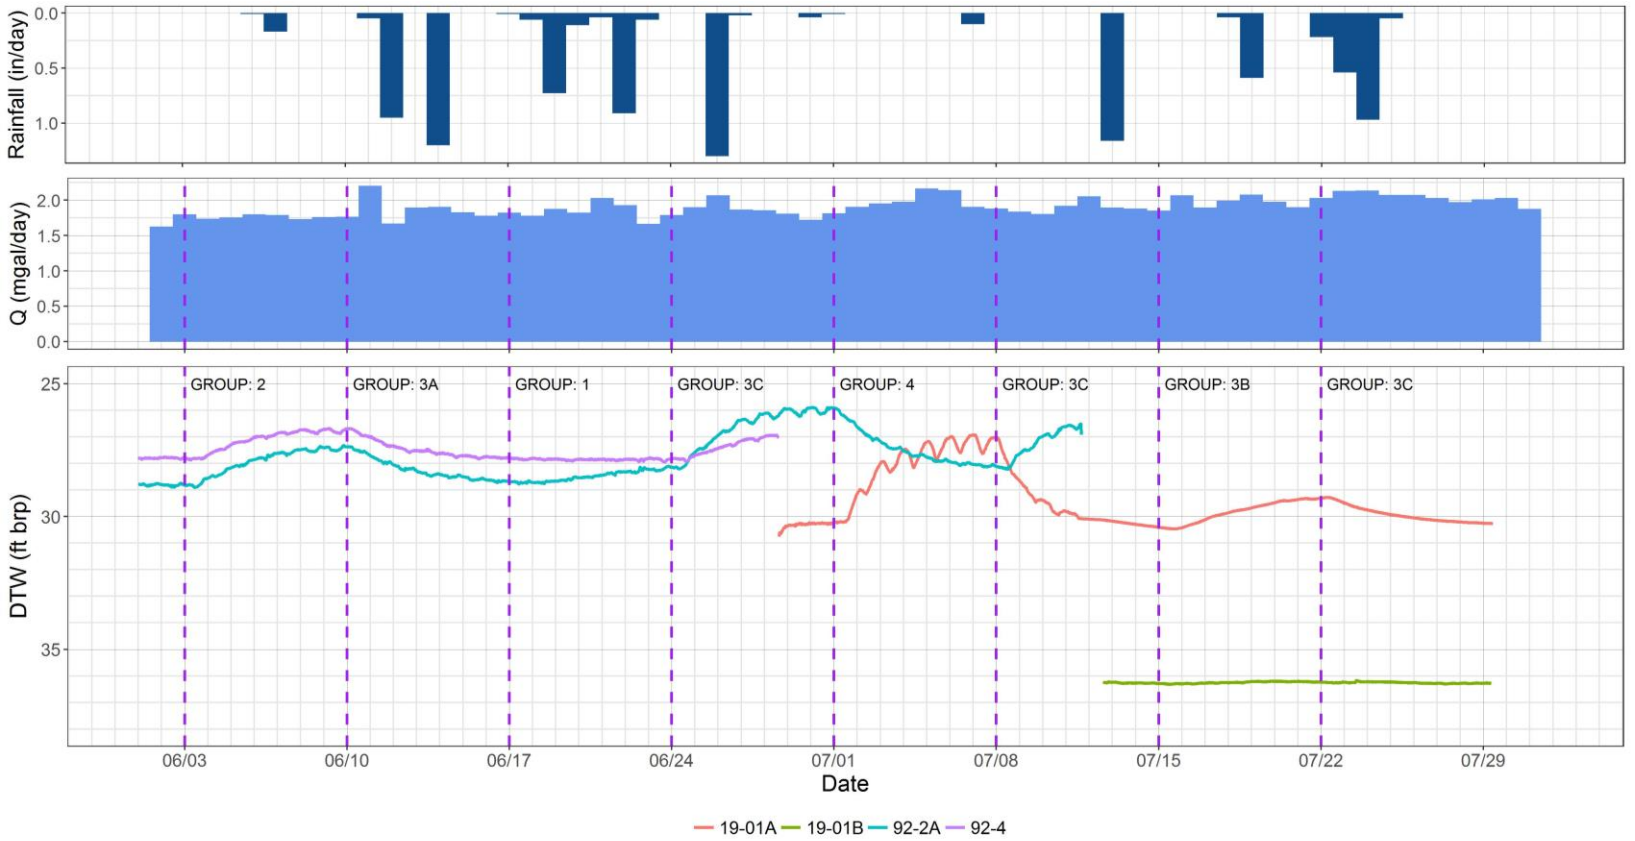

Figure 14: Depth to Water (DTW) Timeseries with Precipitation [top chart], Loading Rate [middle chart], and Loading Group Transitions

The transitions between loading groups are shown with the purple dashed lines along with the water levels in corresponding color-coded lines on the bottom chart in **Figure 14**. In general, the water levels exhibit various degrees of change in response to the focused loading. The increase in water levels in the wells screened in the upper layer ranges from approximately 1 to 4 feet. The recession periods after loading range from several days to approximately one week; however, the longer recession periods may be an indication of effects from loading in nearby groups.

The transducers were installed at 19-01A and 19-01B during the last two weeks of testing, when loading was applied to the two groups immediately adjacent to the monitoring well pair. The depth to water significantly decreases in 19-01A during testing in Group 3B but does not change significantly in 19-01B. The 19-01B well screen was installed below a clay/silt layer indicated in the boring log, and the lack of water level response supports the observation that the well is screened in a separate underlying aquifer unit that appears to be almost entirely disconnected hydraulically from the upper, shallow, water table aquifer unit.

2.5 Geophysics Transects

Geophysical surveys were conducted at the BWPCF recharge beds by Hager GeoScience (HGI) on July 11 and 12, 2019. The survey objectives were to identify the spatial variation of the depth and thickness of the clay/silt layer. Details of the investigation and results from all survey transects are including in **Appendix D**. **Figure 8** (above in **Section 2.2**) shows the transects for ground penetrating radar (GPR) as pink lines and the transects for the mult-channel analysis of surface waves (MASW) as green lines.

The boring from 19-01 shows the undifferentitated sands in the top 75 feet and a clay/silt layer at 80 ft bgs. The GPR survey line adjacent to boring 19-01 is shown in **Figure 15.** A MASW seismic survey from south to north through the site is shown in **Figure 16.** The GPR and MASW results agreed on the approximate depth of the top of clay. Cross-sections for all transects are included in **Appendix D**.

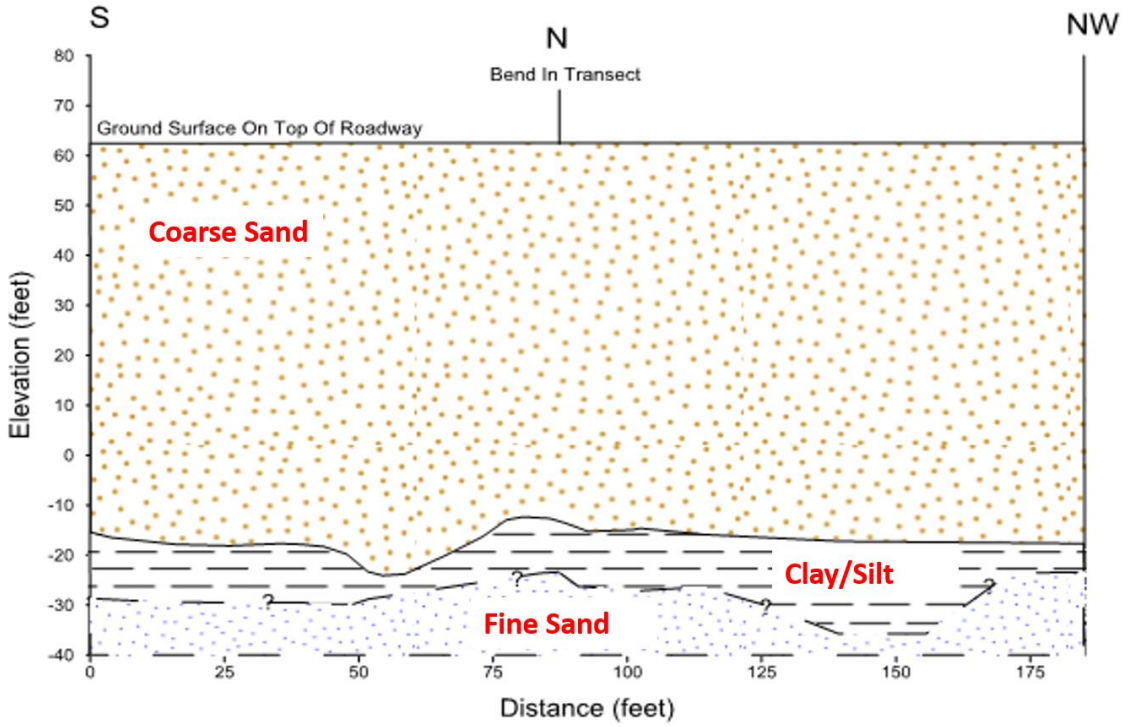

Figure 15: GPR Survey Line 1 – South to Northwest in Southwest Corner of Recharge Beds near New Boring 19-01

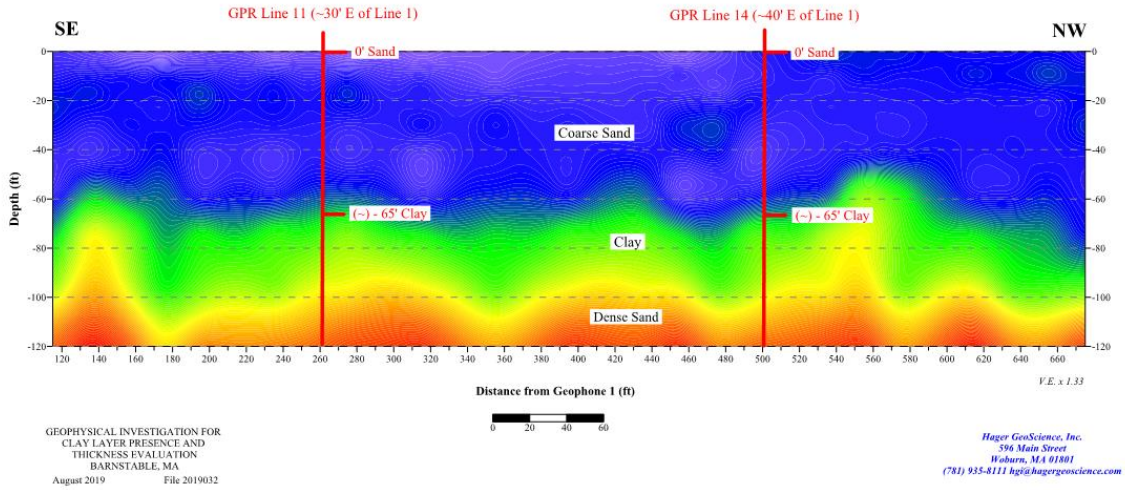

Figure 16: MASW Seismic Survey Line 1 – South to North through Beds 32, 27, 24 and 22

Interpretations of the top and bottom of the clay layer were made for the ten GPR profiles. The thickness was inferred based on the GPR signal velocity. The top of clay is estimated to be present throughout the site at depths of 55 to 107 ft bgs. The clay is 5 to 20 feet thick.

Based on the GPR and MASW seismic surveys, the estimated top of the clay elevation is shown in **Figure 17**. The top of clay is highest (red/orange) in the northern and western edges of the site near beds 11, 12, 15, and 25 (text box **(a)** in **Figure 17**). There is also a local high area under beds 40

through 49 (text box **(b)** in **Figure 17**). This helps explain why flow applied at these beds results in groundwater rise near the BWPCF office parking lot. Areas of lower clay elevation are beneath beds 18 through 21, 29 through 31, and bed 38.

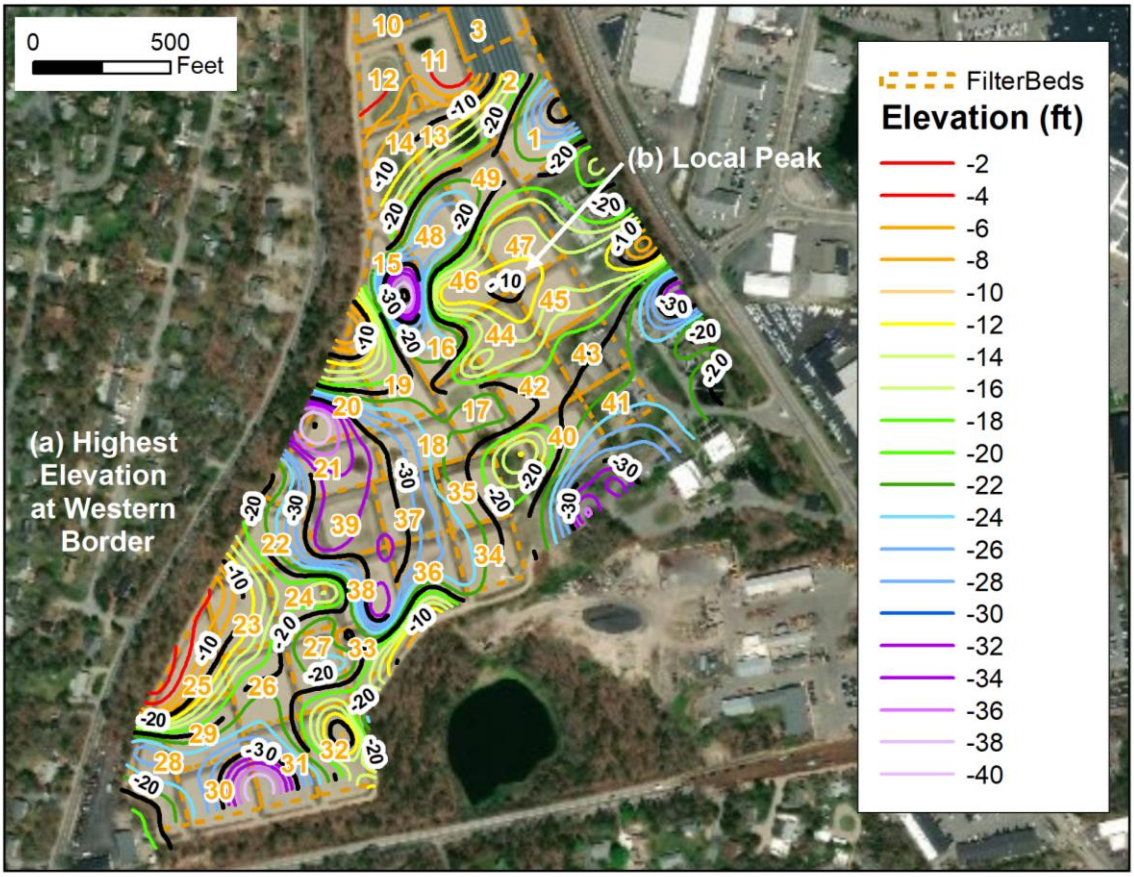

Figure 17: Estimated Top of Clay Elevation

2.6 Data Collection and Field Work Summary

The results from the field testing were used to refine the understanding of the groundwater flow in the area surrounding the BWPCF infiltration beds and update the conceptual site model and numerical groundwater flow model discussed in **Section 3**. The boring logs, GPR transects and seismic surveys were used to identify the approximate thickness and extent of a local clay layer present beneath the infiltration beds. The clay is present throughout the site at 55 to 107 feet below ground surface and ranges between 5 and 20 feet thick. The clay layer restricts vertical flow, as evidenced between the large head difference observed at 19-01A and 19-01B, as well as the lack of response in 19-01B to the focused loading tests. The evidence of the lateral extent of the clay layer is supported by the review of the boring logs from the MassDEP database, which indicates clay beneath the BWPCF and surrounding area at depths of 60 to 80 ft bgs.

The grain size analyses and slug tests were used to refine the hydraulic conductivity estimates of the coarse sand layer above the clay and fine sand layer below the clay. The horizontal hydraulic

conductivity of the coarse sand above the clay estimated from the slug tests ranged between approximately 300 to 500 feet per day. The hydraulic conductivity drops with decreasing elevation, as expected from the gradation observed in the boring logs and decreased hydraulic conductivity estimated from the slug tests conducted at 92-2B. The hydraulic conductivity in the fine sand beneath the clay, as estimated from the slug test results at 19-01B, ranges from 2 to 30 feet per day.

Section 3

Conceptual Site Model and Numerical Flow Model Development

This section describes the Conceptual Site Model (CSM) based on existing data and the results from the field work presented in **Section 2**. The CSM is then incorporated within a numerical flow model to simulate steady-state and transient flow conditions. The numerical flow model is based on previous work from the USGS. Updates to the USGS model based on the CSM are described in **Section 3.2**.

3.1 Conceptual Site Model

The groundwater aquifer on Cape Cod has been extensively studied and documented by the USGS and others (Walter and Whelan 2004, Walter et al 2016, Oldale 2001). The aquifer is a "sole-source" aquifer, serving as the only source of drinking water for communities on Cape Cod. Annual extractions by public water supplies were approximately 28 MGD in 2006.

Recharge from precipitation is the primary source of recharge to the aquifer. Estimates of recharge from USGS steady-state modeling range from 27 inches per year to 30 inches per year. Recharge at ponds is around 16 inches a year due to evaporation during the summer months. Recharge at wetlands varies depending on the growing season, but the net recharge is estimated to be zero inches per year due to evapotranspiration.

A secondary source of recharge is from treated wastewater return flow through septic systems and wastewater disposal facilities. Approximately 80% to 90% of the water extracted from local wells is returned to the aquifer through wastewater return flows.

The Cape Cod aquifer is comprised of glacial sediments over bedrock. The sediments were deposited at the margin of the continental ice shelf. The surficial geology includes glacial outwash plains, moraines and ice-contact deposits. The BWPCF recharge beds are underlain by glacial outwash sediments. These sediments are coarse near the ground surface and become finer with depth (more silt and clay).

Boring logs advanced as part of the 2019 site investigation at the BWPCF and the geophysical survey identified an extensive clay and silt layer under the site. The observed head difference of 6 ft and lack of response to changes in load locations during focused loading at the well beneath the clay/silt indicates the layer functions as an aquitard. The depth of the layer is variable from 55 to 107 ft bgs. Borings outside the site suggest the clay is laterally extensive and generally at an elevation of approximately 0 to -40 ft NGVD29.

Kettle holes, formed by the blocks of ice left by the retreating glaciers which subsequently melted, are present throughout the outwash plain. Many of these locations are now ponds or wetland areas. These ponds often do not have stream inlets or outlets and reflect the underlying groundwater table.

At the coastal boundary, the higher density saltwater forms a wedge underneath the freshwater forming a freshwater and saltwater interface, shown in **Figure 18**. There is negligible flow across the freshwater/saltwater interface and the freshwater at the coastal boundary flows upwards to discharge along the coast at harbors, Cape Cod Bay and Nantucket Sound.

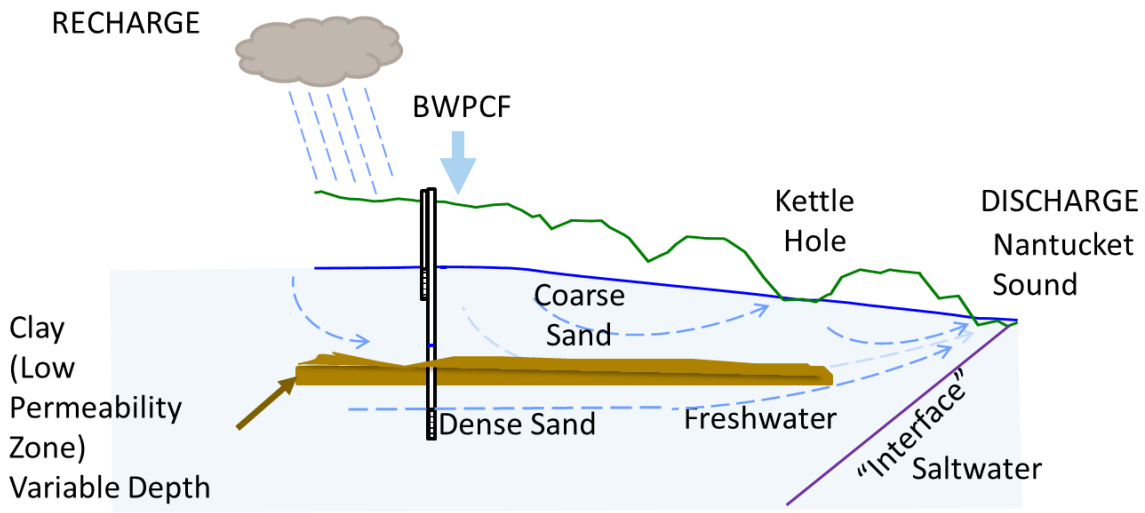

Figure 18: Conceptual Site Model – BWPCF

3.2 Numerical Groundwater Flow Model Updates

The groundwater system on Cape Cod has been studied and modeled for many decades. The previous Barnstable model (GHD, 2017) was based on a steady-state regional model developed by the USGS in the early 2000's (Walter and Whelan, 2004). This USGS model was the basis for the development of contributing areas to streams, harbors and estuaries to support the Massachusetts Estuaries Project (MEP). The USGS continues to enhance and improve the regional Cape Cod groundwater models. Recent updates in 2016 (Walter et al., 2016) improved the ability of the USGS regional model to simulate the interaction of the water table with the ground surface and transient fluctuations in the water table. These changes include the measured ground surface, updating the layering to simulate the water table in the top layer of the model, and changes to the method for simulating streams (Walter et al., 2016). The 2016 USGS model was also modified to allow for the prediction of sea level rise impacts on groundwater. The 2019 Barnstable model is based on the 2016 steady-state USGS model with updates to reflect transient inputs near the BWPCF and subsurface features identified as part of the field work for this project.

3.2.1 Grid Refinement

The base USGS model contained uniform grid cells of 400 by 400 feet. The model grid was refined in the area surrounding the BWPCF to allow for modeling the impacts of recharge applied to the individual cells. The updated model grid near the BWPCF is shown in **Figure 19.**

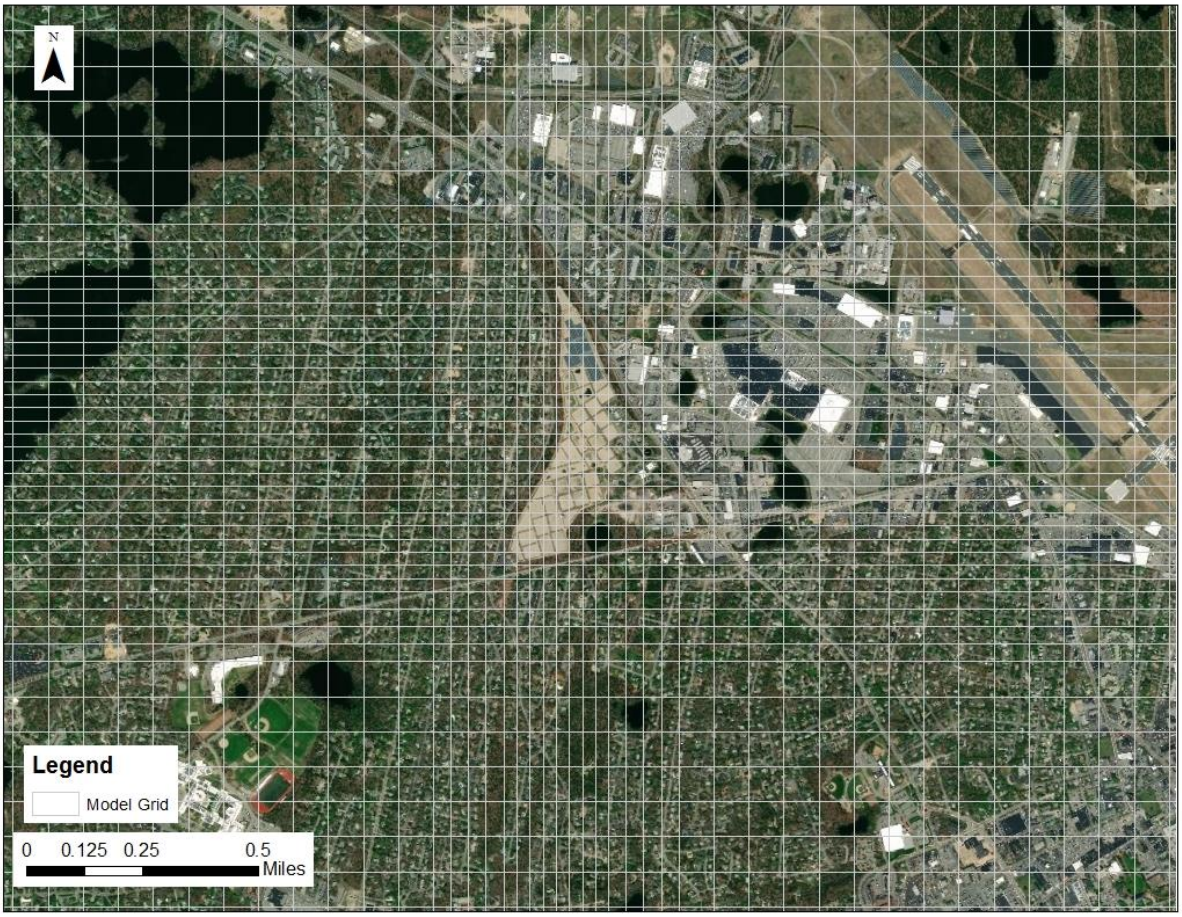

Figure 19: Updated Model Grid near the Barnstable Water Pollution Control Facility

The minimum cell size in the updated model grid is 150 by 150 feet, which better captures the area of the individual infiltration beds. Vertical discretization for simulating observed sediment layering and changes in hydraulic conductivity was taken from the USGS model and was unchanged. The clay/silt layer measured during the field work portion of this project was added to the existing vertical layering within the model, which aligned approximately with the elevation and thickness of the measured clay/silt layer. Future work could include additional vertical discretization to better approximate the top and bottom elevation of the clay layer, however, the existing model discretization was adequate for the simulation modeling presented in this report, as demonstrated by the model calibration. Improved vertical discretization of the clay layer would allow for improved simulation of highly-localized impacts, such as the ponding near the BWPCF parking lot and office building.

3.2.2 Hydraulic Conductivity Property Changes

The field work presented opportunities to update the USGS model within the vicinity of the BWPCF to better represent the local clay and sand layers. A summary of the hydraulic conductivity property changes made to the updated model are provided in **Table 5.** Hydraulic conductivity values were selected based on calibration to observed water level data.

Table 5: Hydraulic Conductivity Property Changes Summary

Aquifer Unit	Model Layers	Horizontal Hydraulic Conductivity (ft/day)	Vertical Hydraulic Conductivity (ft/day)	USGS SLR Model Horizontal Hydraulic Conductivity (ft/day)
Coarse Sand, BWPCF	1 through 3	350.0	35.0	120 to 200
Sand	1 through 3	175.0	17.5	30 to 200
Clay/Silt	4 and 5	1.0	0.01	30 to 200
Fine Sand	6	10.0	1.0	30 to 200

The clay layer located approximately 55 to 107 feet below ground surface was incorporated into the model into 10-feet thick layers sloping downward towards the south with horizontal hydraulic conductivity of 1 ft/day and vertical hydraulic conductivity of 0.01 ft/day. A sensitivity analysis was conducted on the vertical hydraulic conductivity and it was determined that the low vertical hydraulic conductivity in the clay was necessary to match the head difference at 19-01A and 19-01B, which are screened in the upper and underlying aquifer units respectively.

The slug test analyses indicated high hydraulic conductivity in the shallow coarse sand underlying the BWPCF above the clay/silt layer. The area immediately surrounding the BWPCF in the USGS model had a higher hydraulic conductivity than surrounding areas but did not include the local clay layer. A clay layer was incorporated into the model using existing vertical discretization and the horizontal hydraulic conductivity in the water table aquifer at the site (within an approximately 3,000-foot radius) was increased to 350 ft/day to reflect the results from the slug test analyses. The horizontal hydraulic conductivity in the coarse sand in the general area extending from Lake Wequaquet to Mill Creek and spanning the groundwater divide to the southern coast was increased to 175 ft/day to better match well observation points used in the calibration.

3.2.3 Storage Properties

The specific storage and specific yield properties were left unchanged from the previous USGS model (Walter et al., 2015). The specific storage and specific yield parameters were 0.000015 (/ft) and 0.25, respectively.

3.2.4 Return Flow and Recharge

Several updates were made to the return flow and recharge rates in the steady-state and transient models. The updates were made to reflect reported recharge at individual beds at the BWPCF and recharge from recorded precipitation during the transient model simulation period. The return flow and recharge rates published in the 2016 USGS model (Walter et al., 2016) were used as the basis for the updates described in this section. No changes were made to the return flow outside of the Barnstable town limits from both septic and wastewater disposal recharge.

Several updates were made to the groundwater recharge from the wastewater disposal at the BWPCF. The model grid refinements near the facility were made to better represent the recharge from individual beds or groupings of beds. The steady-state recharge at the facility was estimated from the long-term average reported recharge from January 2014 through December 2018. The transient

recharge was set to the reported rates from January 2014 through August 2019 distributed to the corresponding recharge beds. In addition to the changes due to wastewater disposal, the septic recharge was updated to remove areas within the town that are serviced by sewer systems.

Precipitation recharge was updated model-wide in the transient simulation model based on the reported precipitation recorded at the Barnstable Hyannis Airport Weather Station through the period from January 2014 through August 2019. Monthly evapotranspiration and evaporation rates were taken from the Massachusetts Crop Evapotranspiration and Potential Evaporation Grids, developed by Fennessey and Vogel (2000) and available for download online. Recharge applied to the general aquifer was estimated by scaling the recorded precipitation by a monthly factor based on the monthly aquifer recharge rate published in the 2004 USGS Report (Walter et al., 2004). Recharge applied to wetlands was estimated using the reported precipitation minus average monthly evapotranspiration and average monthly evaporation. Finally, recharge applied to open waterbodies (ponds) was estimated using the reported precipitation minus average monthly evaporation. The estimated recharge rates to the ponds and wetlands follow the method described in the 2016 USGS report (Walter et al., 2016). The updated recharge rates reflect variations between January 2014 through August 2019 while remaining consistent with the average recharge rates used in the steady-state model.

3.2.5 Groundwater Pumping

Groundwater pumping rates in the steady-state and transient models were updated to reflect recent pumping data obtained for wells located in Hyannis and those owned and operated by the Barnstable Fire District for the period between January 1, 2001 and February 28, 2019. The average annual pumping value from 2001 through 2018 used in the steady state model and maximum daily pumping rates is shown in **Table 6**.

Table 6: Public Water Supply Wells near BWPCF Owner and Withdrawal Rates

Well Owner	Well	Long-term Average Rate (MGD)	Maximum Daily Rate (MGD)
Barnstable Fire District	4020000-02G	0.07	2.55
	4020000-03G	0.20	0.76
	4020000-04G	0.20	5.50
	4020000-05G	0.04	0.71
Town of Barnstable Hyannis Water System	Airport-1	0.06	0.34
	HP	0.28	0.61
	MD-1	0.17	0.55
	MD-2	0.11	0.62
	MD-3	0.19	0.60
	MD-4	<0.01	<0.01
	MH-1	0.29	0.86
	MH-2	0.32	0.76
	MH-3	0.42	0.76
	SP	0.37	0.76
	SW-2	0.12	0.84

Section 4
Model Calibration

The steady-state and transient model updates described in **Section 3** were evaluated using the metrics presented in this section to ensure consistency with the previous USGS model and to calibrate the model to site-specific data. A comprehensive list of the model-wide and site-specific numerical model calibration points is provided in **Appendix E.** The electronic deliverable of the steady-state and transient numerical model files is provided as **Appendix F.**

4.1 Steady-state

In general, the updates to the steady-state model preserved the USGS calibration and demonstrated good model-fit in the area surrounding the BWPCF, as shown in **Figure 20** and **Figure 21.** The model-wide calibration points were taken from the data set developed for the USGS model calibration (USGS, 2016). The BWPCF-site calibration points were also added to the model-wide calibration data set.

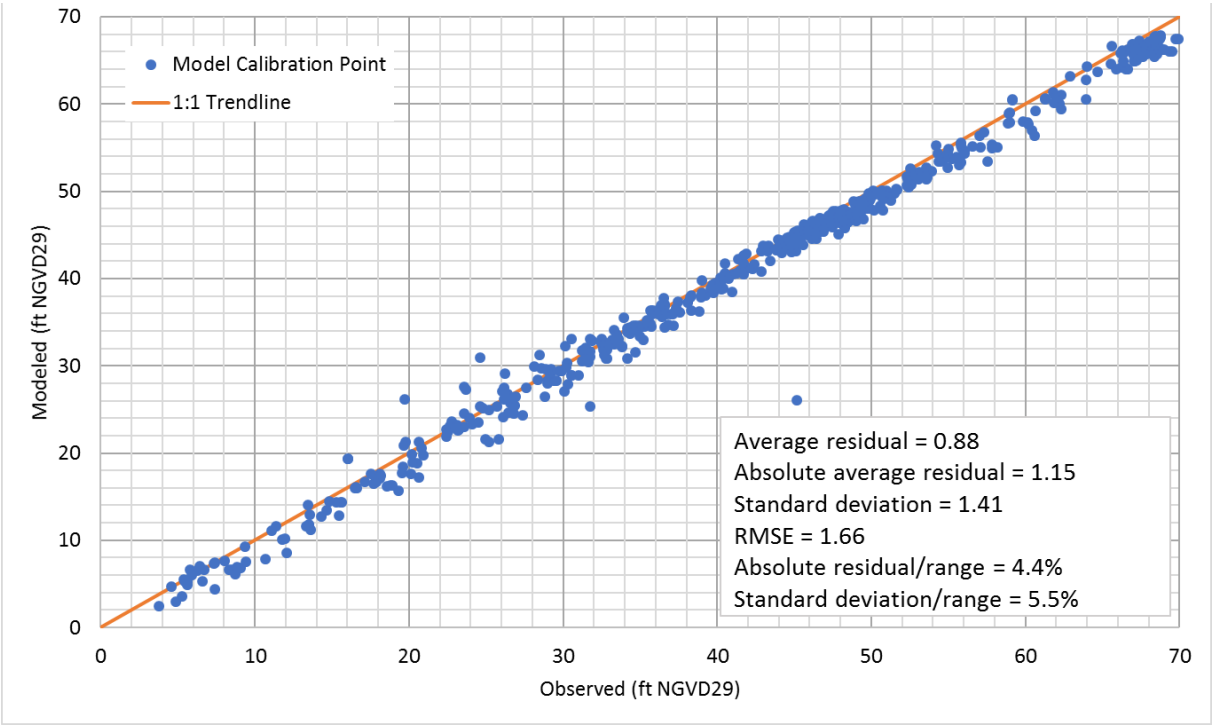

Figure 20: Long-term Observed versus Steady-State Model Simulated Groundwater Elevations – Model Wide

As shown on **Figure 20,** the model-wide calibration matched observation points well. Most model updates were concentrated in the area immediately surrounding the BWPCF, so the model-wide calibration compared to the USGS model was maintained. The average residual was 0.88 feet and the

absolute average residual was 1.15 feet. The absolute residual divided by the range and the standard deviation divided by the range were 4.4% and 5.5% respectively.

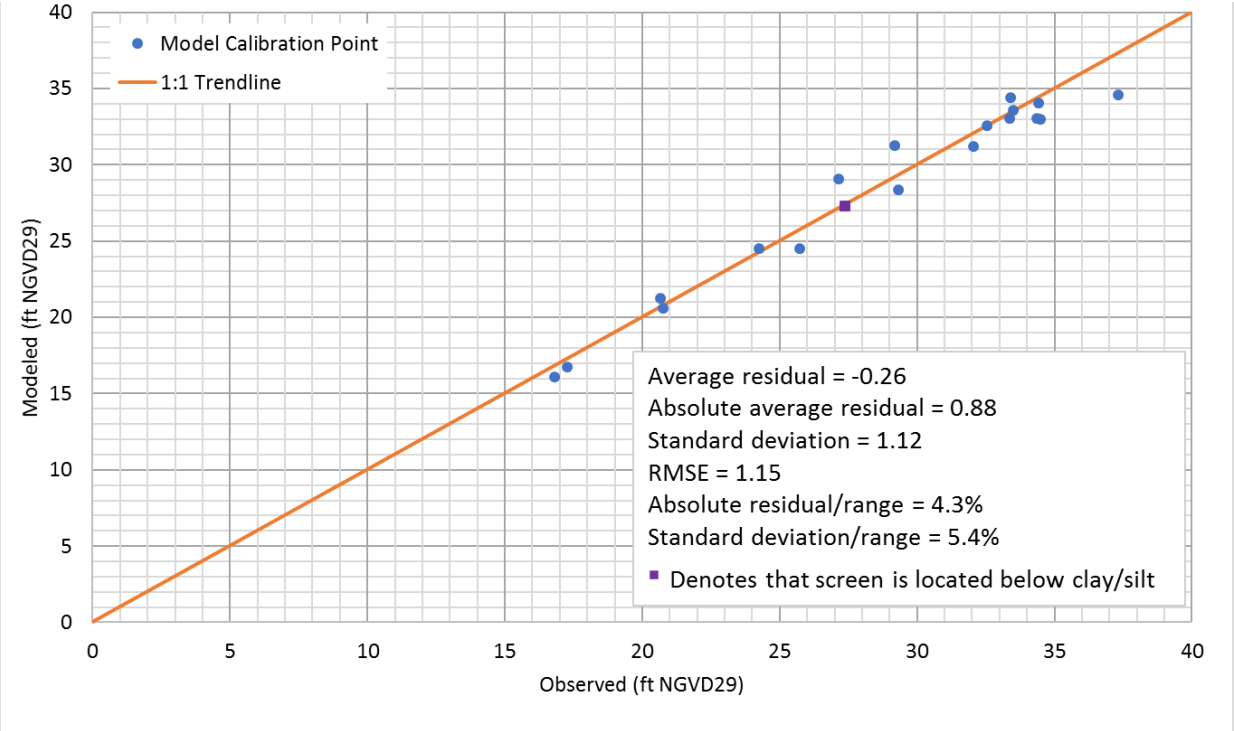

Figure 21: Long-term Observed versus Steady-State Model Simulated Groundwater Elevations – near BWPCF

As with the model-wide calibration, the calibration points located near the BWPCF match the observation points well. The average residual was -0.26 feet and the absolute average residual was 0.88 feet. The absolute residual divided by the range and the standard deviation divided by the range were 4.3% and 5.4%, respectively. The model meets the calibration metrics of the absolute residual and standard deviation divided by the range of approximately 5% for the absolute residual over the range and 10% for the standard deviation over the range. The head contours and residuals for the locations plotted on **Figure 21** are shown on **Figure 22.**

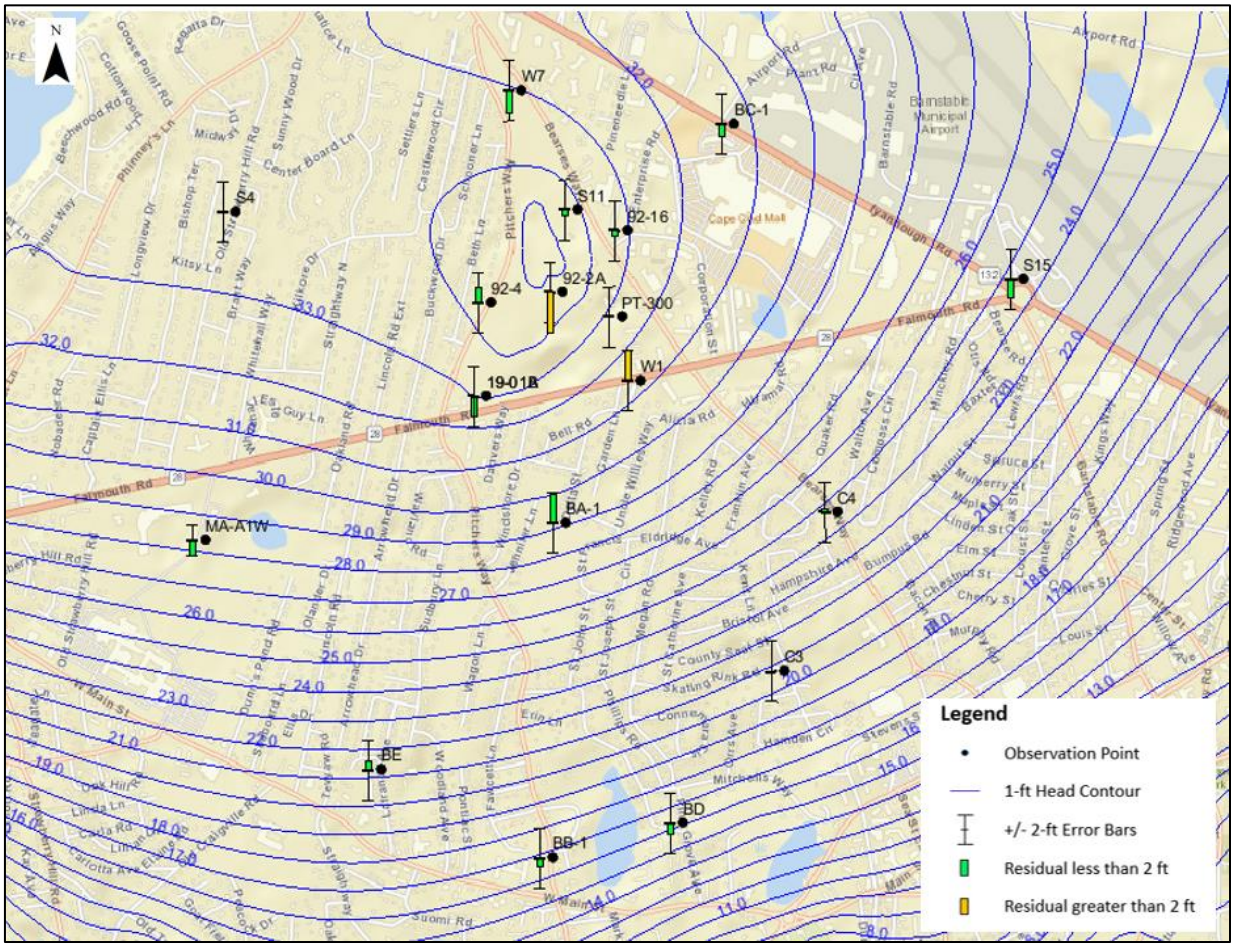

Figure 22: Long-term Observed versus Steady-State Model Simulated Groundwater Residuals and Simulated Water Table Contours - BWPCF Site

As shown in the contours shown on **Figure 22,** recharge at the site causes a local groundwater mound. The water table gradient indicates groundwater flows towards the estuaries and harbors in a south southeasterly direction away from the facility. The model residuals (observed head minus simulated head) are shown in color-coded bars corresponding to the residual length and with two-foot error bars in black. If the modeled groundwater level is within 2 feet of observation point, the residual bar is plotted in green. Yellow bars indicate that the absolute value of the residual is greater than 2 feet. In general, most calibration points are within 2 feet. Model statistics, shown on Figures 20 and 21 indicate the model is well calibrated to observed head data both for the Cape Cod region and near the BWPCF site.

In addition to the comparison of simulated and observed groundwater elevations, streamflows at select locations near the BWPCF and throughout the model domain were compared to observed values. The simulated and observed values are provided in **Figure 23.**

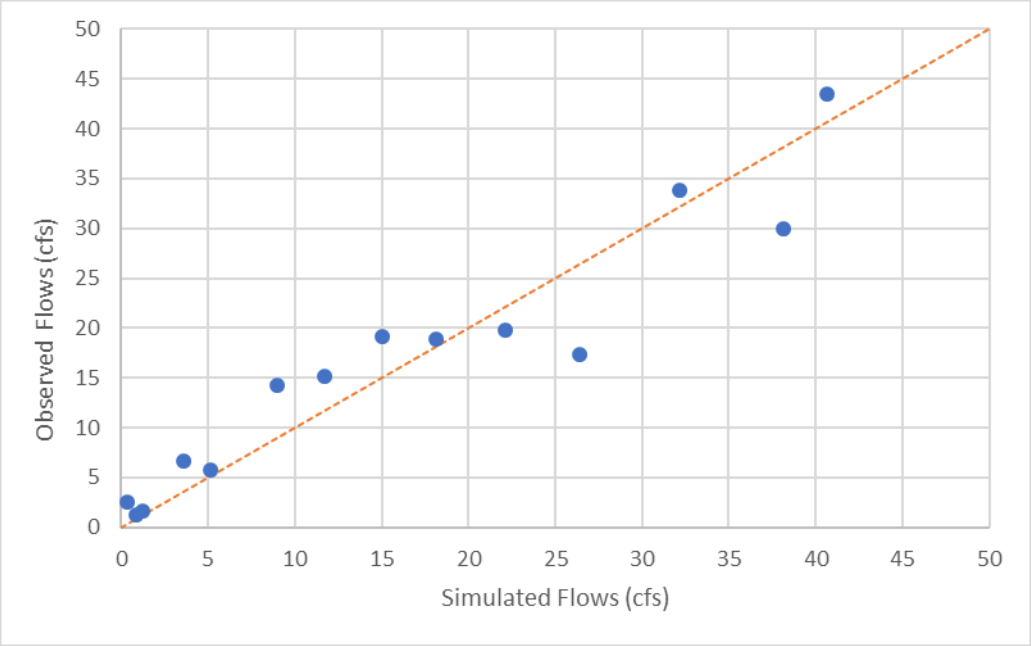

Figure 23. Streamflow at Selected Locations (USGS Gages and Near BWPCF)

The simulated streamflow values generally agree with the observed values, which were taken from Walter et al. (2016). The observed values were compiled by the USGS from several data sources, including USGS streamflow gages and streamflow data collected for the Massachusetts Estuary Project (MEP), and represent approximate streamflow values.

The model-wide steady-state groundwater flow balance is provided in **Table 7.** Published values from previous USGS modeling, including Walter and Whealan (2004) and Walter et al. (2016), are provided for comparison in the table.

Table 7: Steady-State Flow Budget and USGS Reported Values Comparison

Component	USGS Steady-State[1]	USGS Sea Level Rise Model[2]	Barnstable Steady-State Model
Recharge (MGD)	355.3	407	415
Wastewater: Septic and Recharge Beds (MGD)	21.3	24.0	23
Total Recharge (MGD)	**377**	**431**	**438**
Wells (MGD)	-24.9	-28	-28
Discharge: Streams, Coast, Estuaries (MGD)	-358	-375	-424
Total Discharge (MGD)	**-383**	**-403**	**-452**
Percent Discrepancy	*-2%*	*7%*	*-3%*
Percent Wastewater Return Flow	*86%*	*85%*	*83%*

[1] Walter and Whealan 2004. Table 2

[2] Walter et al 2016. Figure 23

Note: Positive numbers indicate flow/flux into the groundwater model. Negative numbers indicate flow/flux out of the groundwater model.

There are no major differences between the model calibration flow budget and the values published in the USGS reports. The percent discrepancy of the model calibration is within a reasonable amount (-3%), and the percent wastewater return flow aligns with the approximate range reported in the USGS reports (Walter and Whealan, 2004; Walter et al., 2016).

4.2 Transient

The changes implemented in the steady state model were applied to the transient model as appropriate. The modeled and observed groundwater levels are provided in **Figure 24** and **Figure 25** for the monitoring wells located within the BWPCF. The model results for all wells used for transient calibration are provided in **Appendix E.**

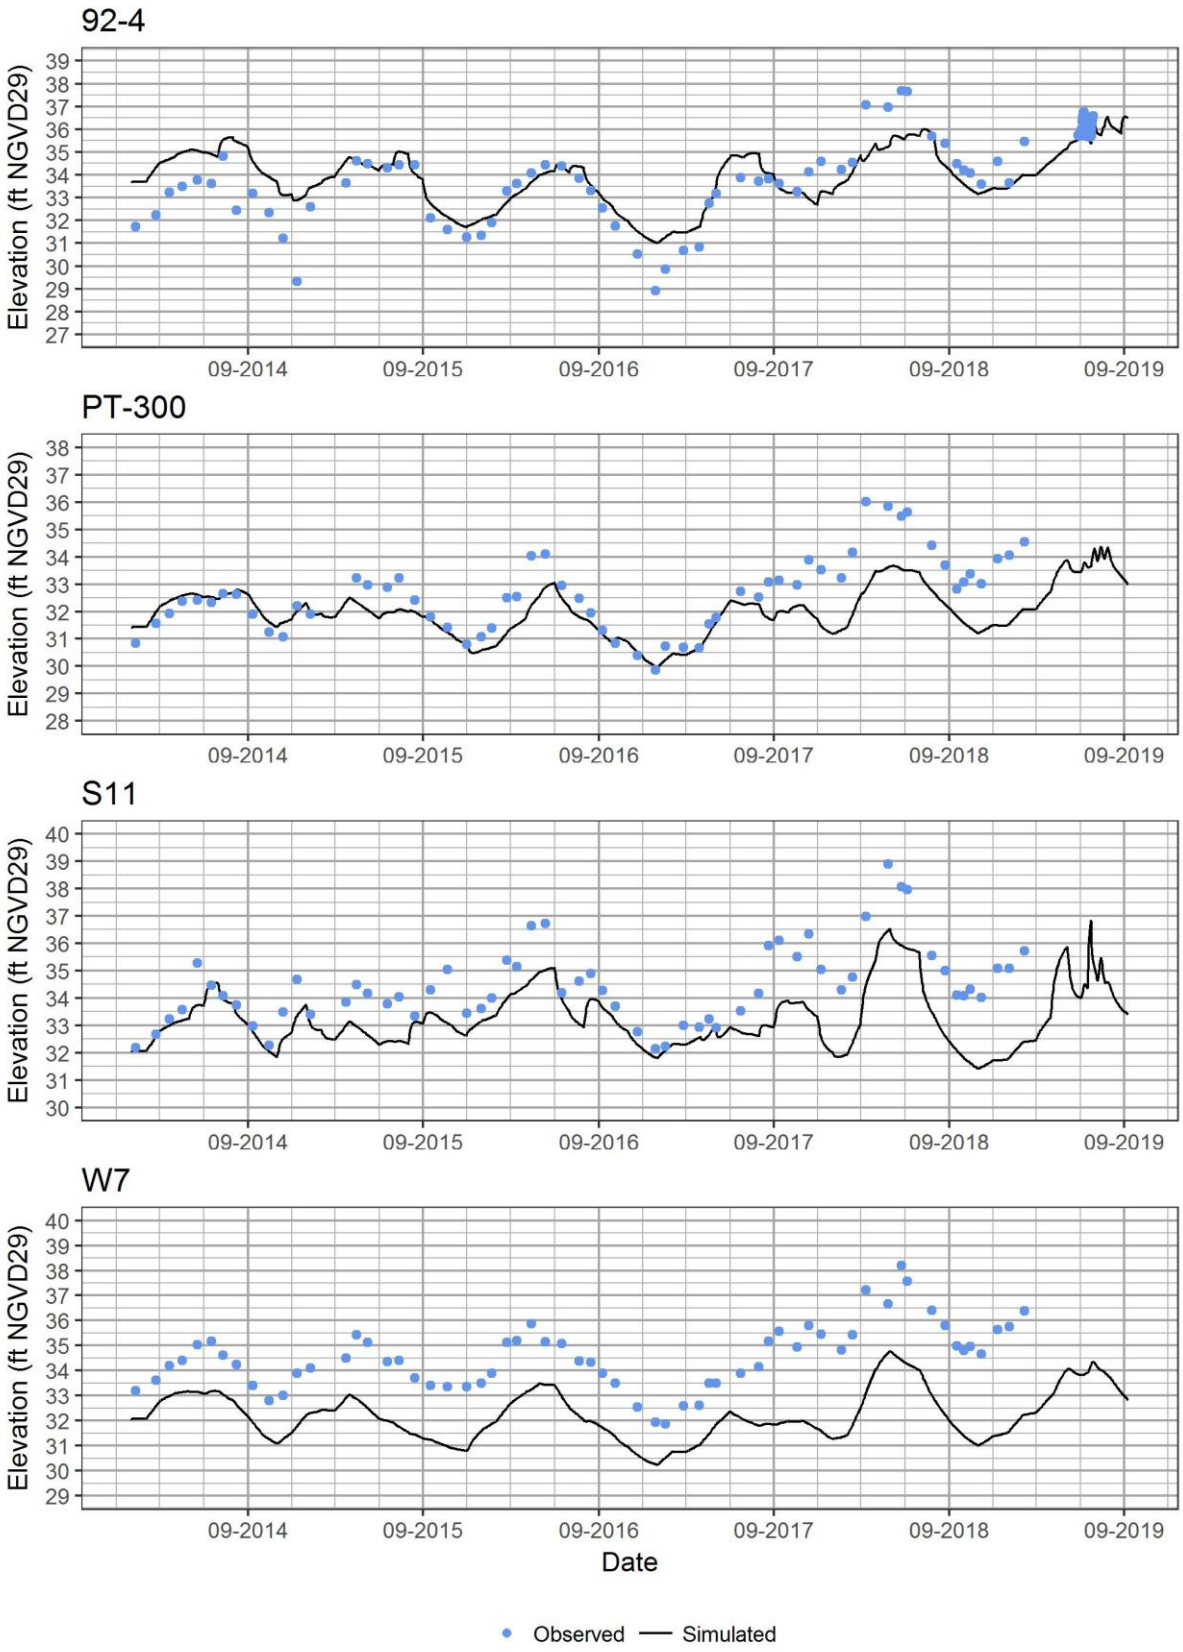

Figure 24: Observed versus Transient Model Simulated Groundwater Elevations (Full Model Simulation)

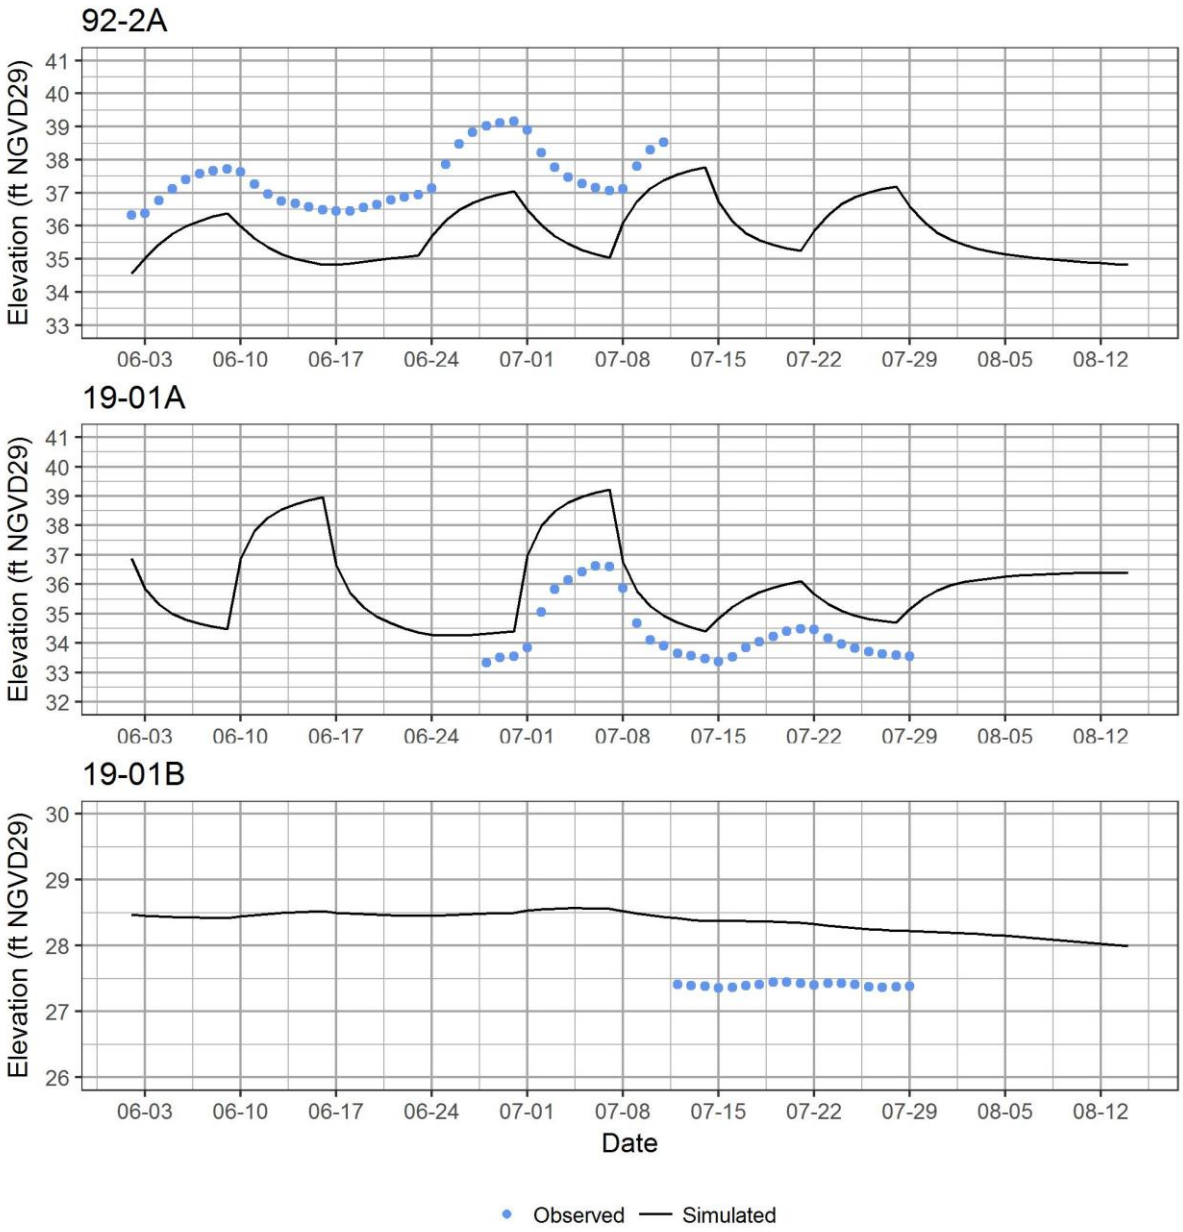

Figure 25: Observed versus Transient Model Simulated Groundwater Elevations (June through July 2019)

The modeled groundwater elevations at the seven monitoring well locations are shown in the black solid line on **Figure 24** and **Figure 25.** The observed groundwater elevations are shown on the plots in blue dots. In general, the transient model captures the seasonal fluctuation in groundwater levels at all locations and matches recent data.

4.3 Model Limitations

The Barnstable model is based on the USGS model documented in Walter et al (2016) which was developed and calibrated to provide regional groundwater flow information to assess the impacts of sea level rise. The Barnstable model was updated and calibrated based on data and hydrologic conditions for long-term average conditions and for transient conditions between 2014 and 2018. The calibration focuses on the BWPCF site and nearby areas. Updates to subsurface features, local recharge patterns and pumping withdrawals have not been included in other areas. Available data and model calibration should be reviewed to determine if additional model updates are required before simulation of scenarios in other areas.

The simulation of lakes and ponds is based on high conductivity values and horizontal flow barriers to simulate the movement of groundwater through the bottom of ponds. The simulation of lakes and ponds should be calibrated to pond water levels and inflow and outflow data prior to application of the model to estimation of pond and lake water budgets.

Estimates of steady-state and seasonal site capacity are dependent on estimated model recharge. The estimated site capacities are based on simulated average annual or average monthly conditions and do not represent all periods, particularly periods of high recharge which could limit site capacity.

The model is well calibrated to observed head and streamflow data both for the Cape Cod region and near the BWPCF site and is appropriate for simulation of existing groundwater conditions and recharge scenarios presented in this report.

Section 5
Scenarios

Five scenarios were developed and simulated utilizing the steady-state and transient calibrated models. Results were compared to baseline steady-state and transient simulations using the current recharge rates at the BWPCF. Scenario 1 looks at the transient capacity at the BWPCF recharge beds. The capacity of the beds is dependent on the groundwater table which varies seasonally. Scenarios 2 and 3 use particle tracks to evaluate the potential for impact to public water supply wells under both steady-state and transient conditions. Scenarios 4A and 4B simulates withdrawal of groundwater downgradient of the BWPCF recharge beds to reduce impacts to low-lying areas. The scenario includes recharge at the maximum day permitted flow rate of 4.2 MGD and recharge at the maximum day build-out rate of 10 MGD using steady-state simulations. Scenarios 5A and 5B simulate the impact to the water table due to a combination of sea level rise, increased groundwater withdrawals and average annual flows of 2 MGD (site capacity) and 6 MGD (build-out) using a steady-state simulation.

5.1 Baseline

Previous studies conducted for the BWPCF have recommended site recharge capacities and identified areas where the existing depth to groundwater is small and structures are present which could be impacted by increases in groundwater levels. Seven areas of concern have been identified in previous studies. These locations are shown in red on **Figure 26**.

A previous study for the BWPCF conducted by Stearns and Wheler (2005) recommended a sentinel well at PT-300 and concluded a head of 36.5 ft or higher at the site would indicate groundwater impacts in downgradient neighborhoods. The study by Stearns and Wheler recommended an average annual discharge capacity of 2.3 to 2.5 MGD. Another previous study by GHD (2017) found that a simulated average annual recharge rate of 1.6 MGD at the BWPCF did not result in depth to water of less than 8 feet downgradient of the BWPCF and identified an area of influence from a 1.6 MGD recharge rate. It is not clear in the report how the area of influence from the model scenario was determined. The GHD report identified issues with high groundwater at Independence Drive, Barnstable High School, Enterprise Road/Cape Cod Mall, and St. Francis Circle with simulated average annual recharge rates at the BWPCF of 3 MGD.

For this analysis the steady-state and transient calibrated models were used as baselines for comparison to model scenarios. The steady-state baseline simulation includes average annual recharge from precipitation, average annual return flow and average annual pumping from nearby public water supply wells. The transient baseline simulation includes aquifer recharge, BWPCF recharge and nearby public water supply transient pumping rates for the period from 2014 through 2018. Steady-state and transient simulations were also run with zero wastewater recharge at the BWPCF recharge beds for comparison with current conditions. **Figure 26** shows the steady-state simulated increase in the groundwater elevation, or “mound”, due to the average annual recharge rate 1.6 MGD, at the BWPCF site. The steady-state simulation shows increase in average groundwater

elevations due to recharge at the BWPCF of greater than 1 foot extending from Route 6 in the north to West Main St in the south.

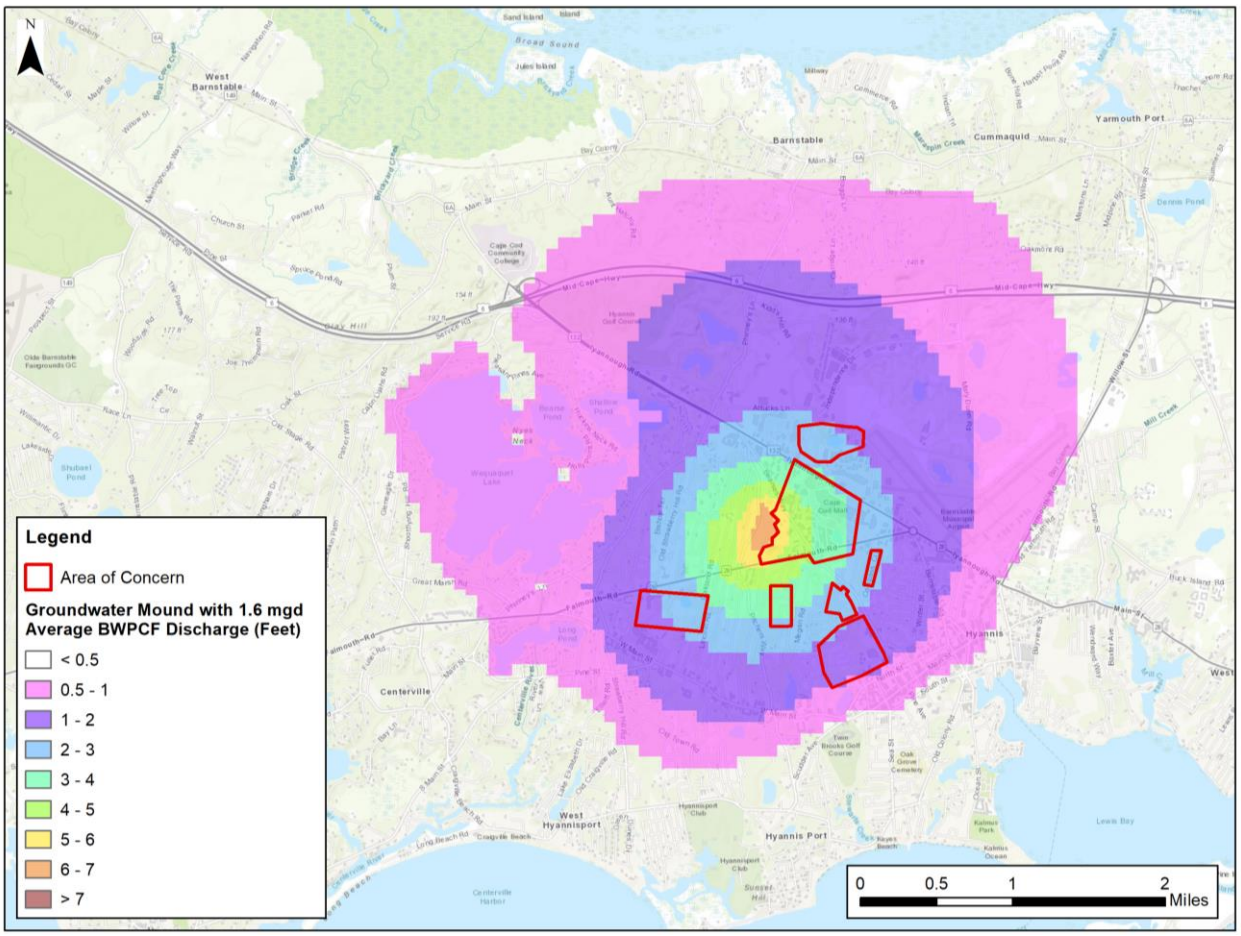

Figure 26: Groundwater Mound due to BWPCF Average Annual Recharge of 1.6 MGD

The recharge capacity of the BWPCF is limited by low-lying areas off-site where increases in the groundwater table could impact basement and low-lying structures. The depth to water is less than 8-ft in the areas identified in previous reports (Stearns and Wheler 2005 and GHD 2017) including near St. Francis Circle and Barnstable High School. **Figure 27** shows the simulated depth to groundwater if there was zero recharge at the BWPCF. This map was developed by subtracting the simulated steady-state groundwater elevations from the digital elevation model of the ground surface. **Figure 28** shows the depth to groundwater for the current average annual discharge rate of 1.6 MGD. For the zero-recharge simulation (**Figure 27**), structures near St. Francis Circle have a steady-state simulated depth to groundwater of greater than 8 feet. One structure near Barnstable High School is on the edge of the area with 6 to 8 ft depth to groundwater. In addition, near Fawcetts Pond to the south there are areas where the simulated depth to groundwater is near 8 feet. The area near Fawcetts Ponds was not identified in previous reports as an area of concern. For the simulated current average annual discharge rate of 1.6 MGD (**Figure 28**), 3 structures in the St. Francis Circle and 4 structures near the Barnstable High School show simulated depth to water of between 4 and 8 feet.

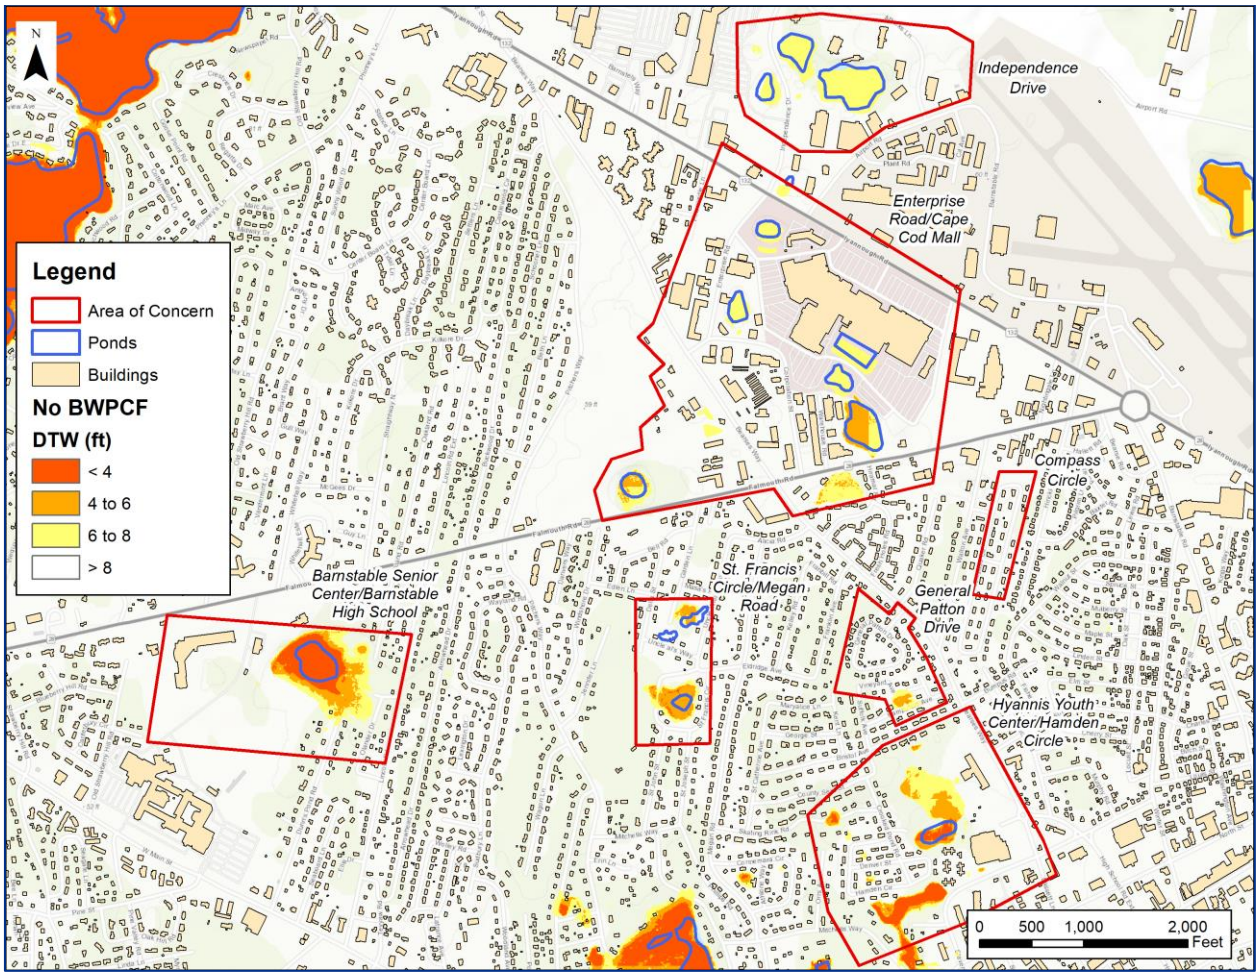

Figure 27: Depth to Groundwater – Zero Recharge at BWPCF

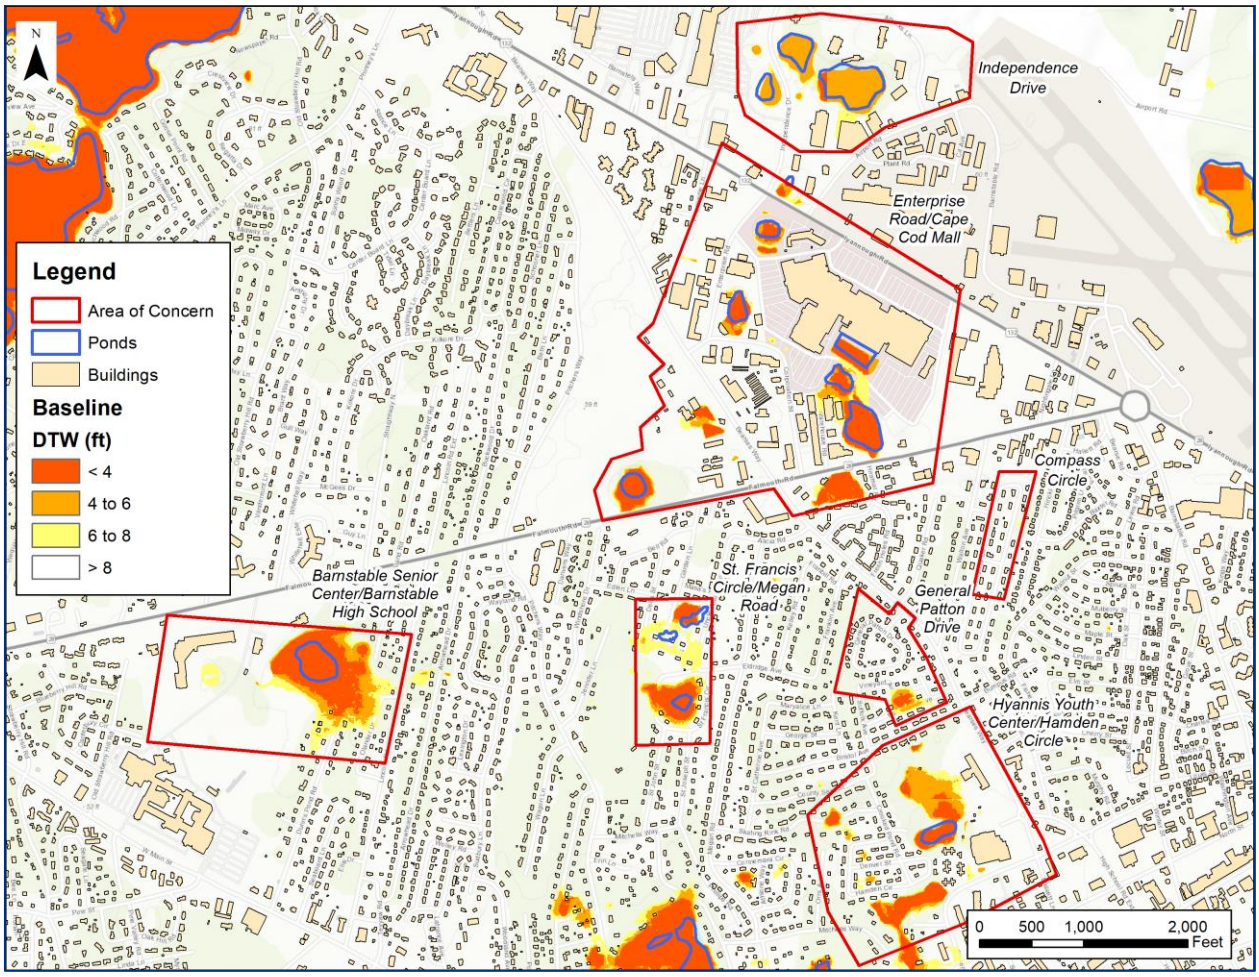

Figure 28: Depth to Groundwater – 1.6 MGD Baseline

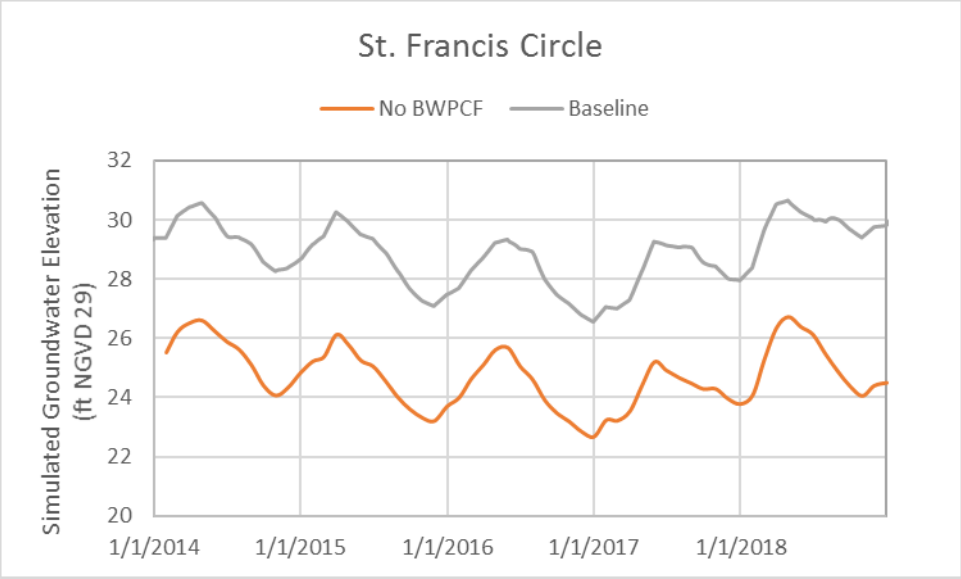
Figure 29 shows the simulated monthly water levels at a location near St. Francis Circle for two transient simulations, zero recharge at the BWPCF and a baseline simulation with reported flows from 2014 through 2018 at the BWPCF. The two transient simulations show that the recharge flow from the last 5 years at the BWPCF increase the groundwater over 3 feet near St. Francis Circle when compared to the zero recharge simulation. Background seasonal fluctuations are between 2 to 3 feet based on the difference between the minimum and maximum water levels during a twelve month period.



Note: Ground surface at this location is 40 ft. Within 500 feet of this location, ground surface varies from 28 ft to 54 ft.

Figure 29: Simulated Groundwater Elevations near St. Francis Circle – No BWPCF and Baseline Conditions

5.2 Scenario 1 – Seasonal Capacity of BWCF

The transient seasonal capacity of the BWCP was determined by determining the average annual site capacity (2 MGD), identifying groundwater elevations at downgradient sentinel points which would be protective of basement and septic systems, and then estimating and simulating the permissible effluent discharge for each month during the 5-year simulation period.

Using the 8-ft depth to water criterion, a steady-state simulation was used to estimate the maximum head at the BWPCF that would limit potential impacts to houses at St. Francis Circle. For this simulation, the flow was assumed to be applied evenly in the southern portion of the site (recharge beds 17, 18 and 20 through 39). A steady-state recharge rate of 2 MGD at BWPCF shows a simulated depth to groundwater of 4 to 8 feet under 9 structures at St. Francis Circle and 7 structures near the Barnstable High School. (**Figure 30**). Increasing flows would result in lower depth to water and more impacted structures. Therefore, this rate of 2 MGD was identified as the estimated average annual recharge capacity for the BWPCF. Based on this simulation, target groundwater elevations were identified for sentinel points near St. Francis Circle and Barnstable High School to guide the transient capacity simulation. The groundwater elevations for the sentinel points are 31 ft for St. Francis Circle and 29.3 ft for Barnstable High School. The groundwater elevations for the sentinel points were taken from the average annual recharge capacity simulation for the BWPCF. These values reflect the groundwater elevations at points in the model that are protective of structures downgradient of the BWPCF.

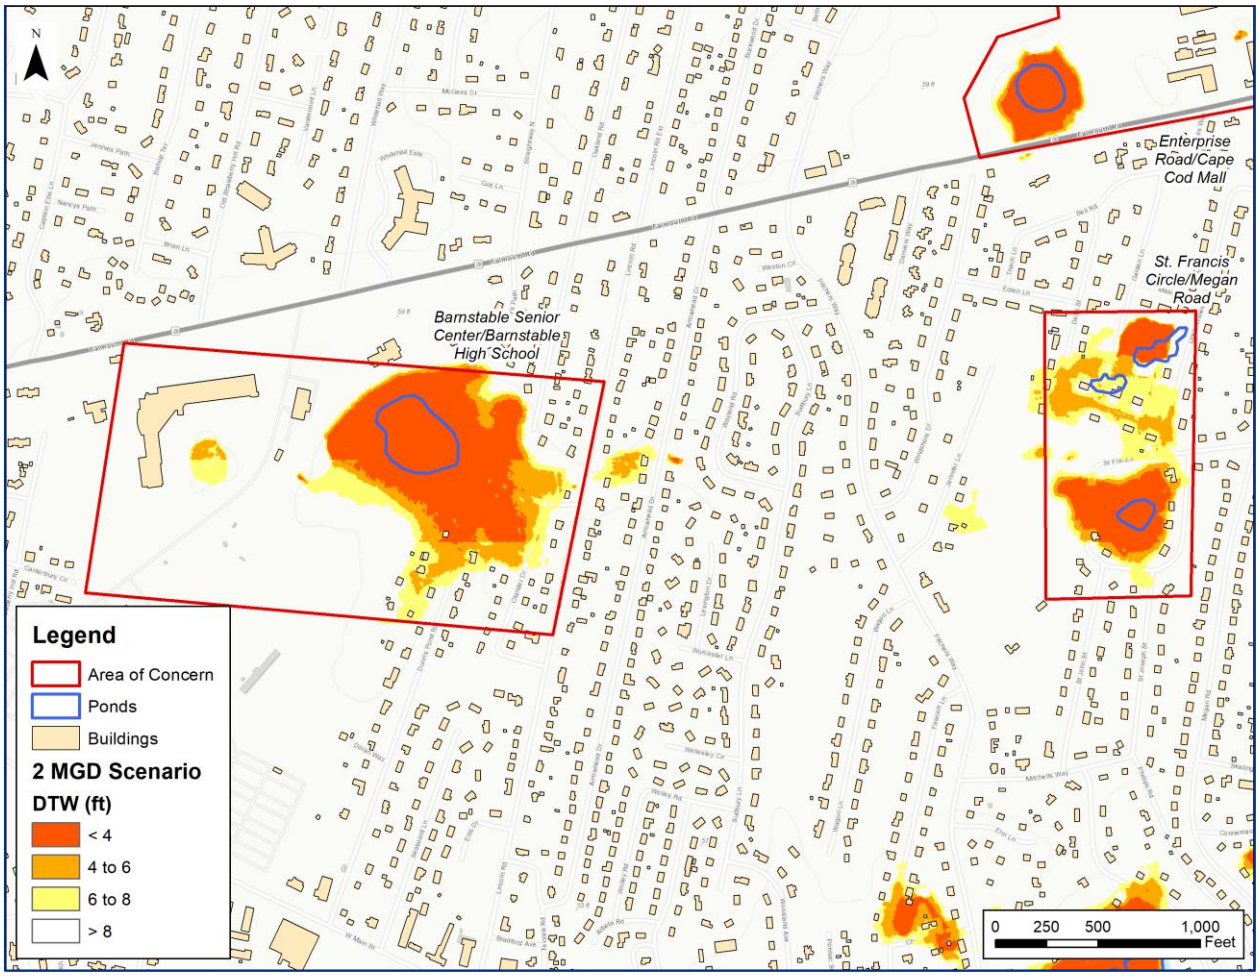


Figure 30: Depth to Groundwater – 2 MGD Planning Scenario

The transient recharge capacity was developed by first estimating the monthly recharge at the BWPCF based on the steady-state simulated water elevation at the sentinel locations. The model was then run in a transient mode to simulate the impacts of the monthly recharge on water levels and the monthly recharge iteratively adjusted to maintain the simulated water levels at the sentinel locations for each time step.

Analysis of the monthly estimated recharge from precipitation, reported BWPCF site recharge and simulated water levels near St. Francis Circle indicates that there is a lag of 3 months in the water table response to changes in recharge, due to aquifer response time. The response time in an aquifer is a function of the change in recharge and boundary conditions (i.e. pumping), the distance to the discharge and boundary locations and hydraulic and storage properties of the aquifer. The lag time was estimated based on the relationship between the sum of the previous 3-months of recharge from precipitation to simulated groundwater levels near St. Francis Circle.

Figure 31 shows the average monthly reported flow at the BWPCF in blue, which range from 1.3 MGD to 2 MGD. The yellow line shows the estimated site recharge capacity based on the linear estimate. The estimated monthly site recharge capacity ranges from 0.96 MGD to 3.1 MGD. The chart shows

that in April and May of 2016, 2017 and 2018 the reported BWPCF recharge rate was at or above the simulated site recharge capacity. In fall of 2017 and winter of 2018 there were a few months with high precipitation which resulted in high groundwater level. The simulated site recharge capacity dropped to less than the BWPCF flows for several months. This is consistent with reported issues in 2018 including parking lot flooding near the BWPCF office.

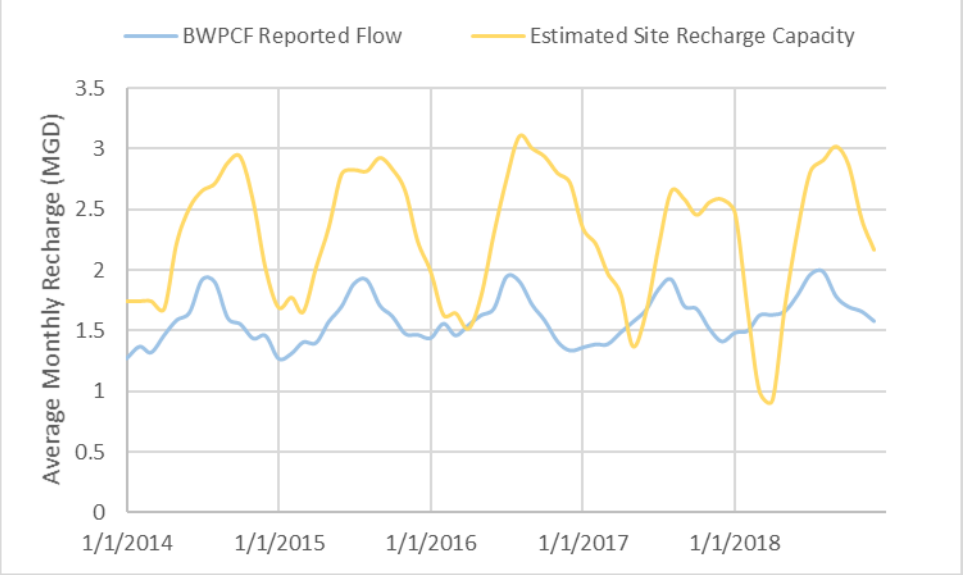

Figure 31: Monthly Reported BWPCF Recharge and Simulated Site Capacity

The Palmer Drought Severity Index (PDSI) is a monthly index developed by the National Oceanic and Atmospheric Administration (NOAA) that provides a method of estimating the severity of wet or dry (drought) periods (NOAA 2019). Negative values are assigned to indicate drought conditions and positive to indicate wetter conditions. The index generally ranges from negative to positive 6 with normal values between -0.5 to 0.5. A value of 3 to 4 is categorized as a "severe wet period" and above 4 as an "extreme wet period."

For this analysis, a timeseries of rainfall was developed from the Barnstable WWTF observed data with missing data from the Barnstable Airport. This 120-year time series was then used to calculate the specific PDSI for the Barnstable area (Cox, T. et al 2019). Starting in August of 2017 through June of 2018, the monthly PDSI values were all greater than 3, indicating severe wet periods. The PDSI values were above 4 for seven of the eleven months, indicating extreme wet periods. For the month of March 2018 the PDSI was 5.54 and for April 2018 the PDSI was 5.11.

Recurrence intervals for this volume of precipitation over a 3-month period were developed based on the long-term rainfall timeseries. Based on the analysis, the rainfall total for the 3-month period from August 2017 through October 2017 would be expected to occur every 18 years and the rainfall total from January 2018 through March 2018 would be expected to occur every 12 years.

The groundwater levels from the simulated baseline using actual BWPCF reported flows and the maximum seasonal capacity model runs at the BWPCF site, St. Francis Circle and Barnstable High School are shown in **Figure 32.** The simulated water levels at the sentinel points near St Francis Circle

and Barnstable High School generally stay below the target values of 31 ft and 29.3 ft respectively. The simulated water levels do drop below the target elevations for some periods, suggesting that seasonal capacity may be underestimated during the fall and periods of low groundwater.

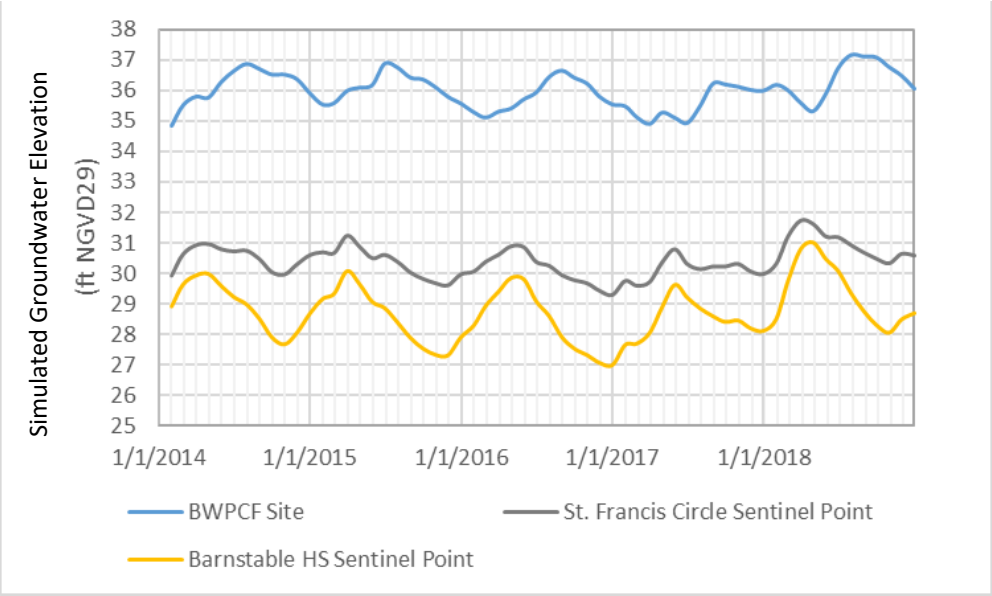

Figure 32: Simulated Groundwater Levels for Maximum Seasonal Capacity at BWPCF Site and near Areas of Concern

Results of the seasonal capacity simulation show that the capacity of the site is dependent on groundwater levels and recharge from the previous months. **Figure 33** shows the average reported flows and simulated capacity for each month at the BWPC for 2014 through 2018. The black error bars show the range in the reported and simulated monthly flows. The yellow shows the estimated plant capacity for each month along with error bars showing the range of capacities. The current flows meet or exceed the site capacity for the months from March through June. During the fall and winter, there is excess recharge capacity at the site.

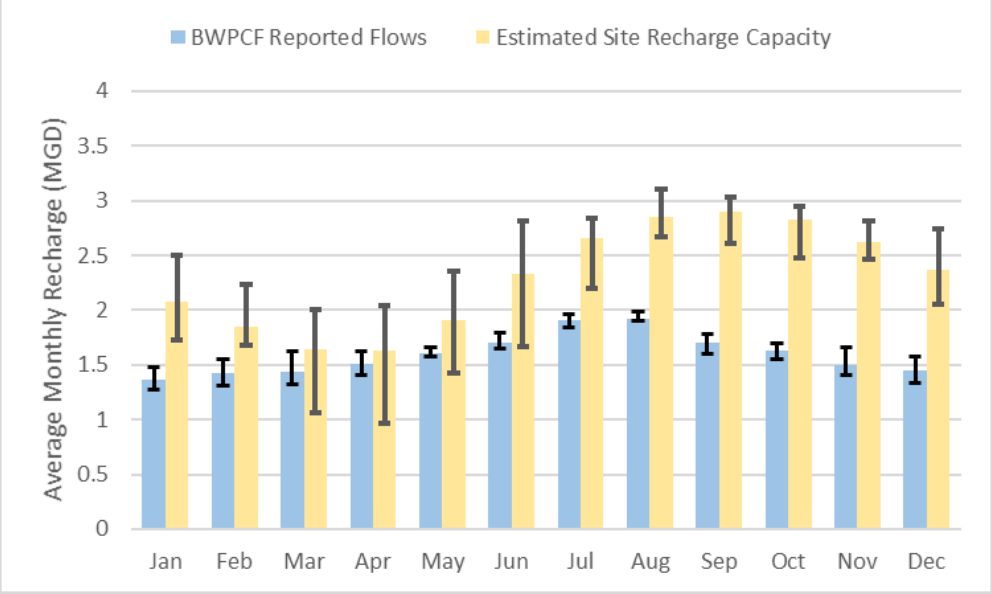

Figure 33: Average Monthly BWPCF Recharge and Simulated Site Capacity

The analysis suggests that a predictive tool for estimating site capacity and guiding operational decisions could be developed. The tool would be used to identify the acceptable BWPCF loading rate on a monthly basis, using groundwater levels from sentinel wells, background wells away from the site, and/or precipitation and temperature data. This would require collection of water level data at St. Francis Circle to evaluate the response to bed loading rates, precipitation data and identification of an off-site sentinel well which is not impacted by the BWPCF.

5.3 Scenario 2 – Travel Time to Public Water Supply Wells

The travel time to nearby public water supply wells was simulated using current pumping rates from 2014 through 2018 and the 5-year transient baseline model. The assumed porosity value was 0.3. To estimate the impact associated with wastewater discharge at the BWPCF beds, particles were released from the individual cells corresponding to the BWPCF beds. A total of 6 evenly-spaced particles were released at the water table in each cell. Two sets of particles were released in January 2014 and July 2014 to evaluate seasonal differences, if any. The resulting particle pathways at the end of the 5-year simulation are shown in **Figure 34.** No particles reach the nearby public water supply wells after a period of 5-years at the current public water supply pumping rates and average annual BWPCF recharge rates. Outside of the 5-year time of travel, there are generally no additional treatment requirements for total organic carbon (TOC).

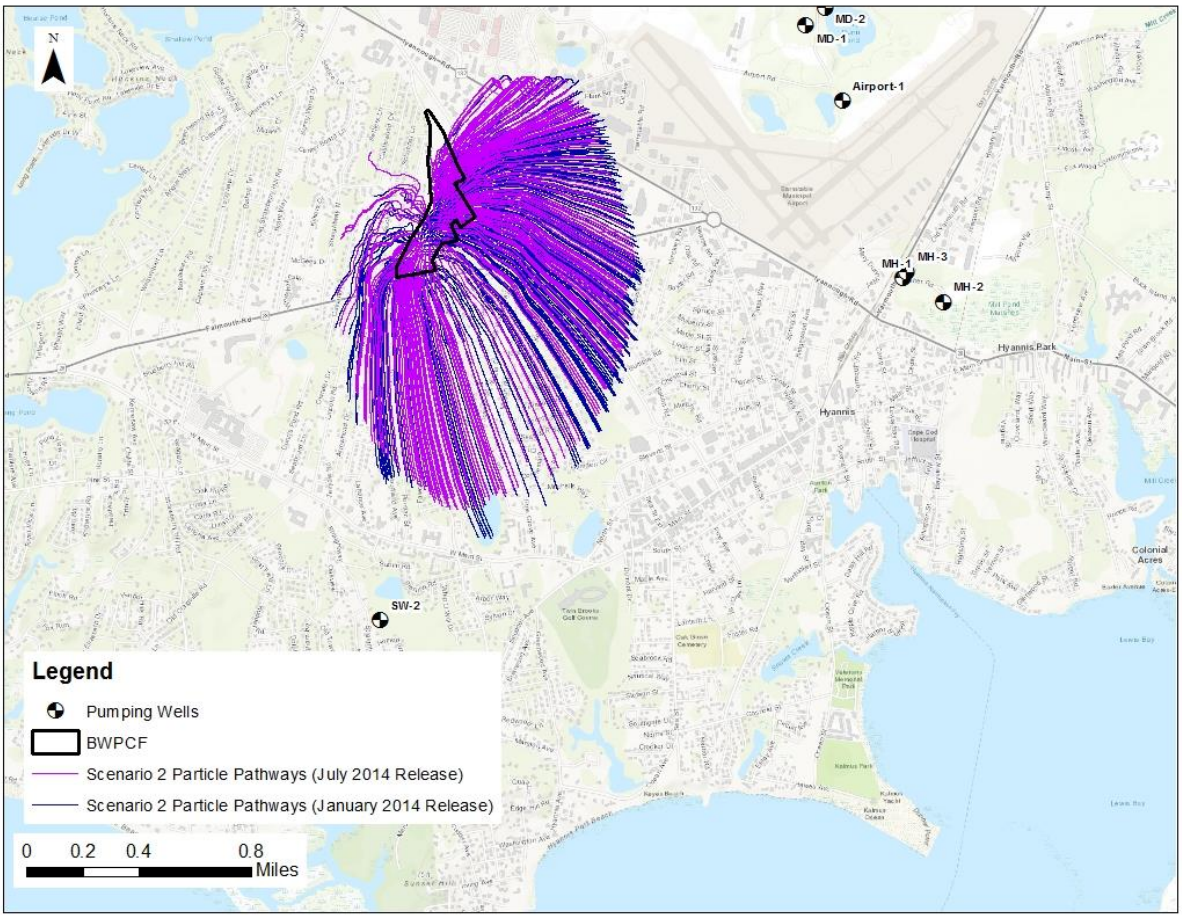

Figure 34: Simulated 5-Year Particle Pathways (January 2014 Release)

5.4 Scenario 3 – Travel Time to Public Water Supply Wells under Maximum Sustained Pumping

The travel time to nearby public water supply wells under maximum sustained pumping was estimated using the steady-state model. Average annual recharge from precipitation and the estimated average annual site capacity of 2 MGD at the BWPCF were assumed for this scenario. The potentially impacted public water supply wells identified are listed in **Table 8,** along with the simulated travel time of particles that terminate at the public water supply wells. As with Scenario 2, the assumed porosity value was 0.3. A total of 6 evenly-spaced particles were released at each cell corresponding to an individual recharge bed at the BWPCF.

Table 8: Public Water Supply Wells Withdrawal Rates and Time of Travel from BWPCF for Scenario 3

Well	Long-term Average Rate (MGD)	Maximum MassDEP Approved Withdrawal Rate (MGD)	Simulated Travel Time (years)
HP	0.28	0.72	44.1
MH-1	0.29	1.01	21.4
MH-2	0.32	1.01	26.8
MH-3	0.42	1.01	21.4
SP	0.37	1.01	17.4

The long-term average withdrawal rates for all wells are relatively consistent and range from 0.28 MGD to 0.42 MGD. The maximum MassDEP approved withdrawal rates are 0.72 MGD at Well HP in Hyannisport and 1.01 MGD for all other wells. The five public water supply wells are all located south/southeast of the BWPCF.

Particles all move radially initially from the site. The particles which flow to the west and north/northeast change directions after approximately 0.25 miles, when they are pulled south and east by the influence of the public water supply wells The screen for well SW-2 is located in a deeper aquifer unit from SP and HP, which are screened in the shallow aquifer, and thus particle pathways do not terminate at SW-2. The travel times for the particle pathways are all much greater than 5 years. The minimum travel time for each public water supply well, shown in **Table 8,** is greater than 17 years for all wells.

5.5 Scenario 4A/4B – Feasibility of Focused Groundwater Withdrawals to Improve BWPCF Capacity

The steady-state model was used to evaluate the feasibility of focused groundwater withdrawals between the BWPCF site and potentially impacted downstream areas. The goal of the scenarios was to estimate the amount of withdrawals required to maintain water levels at a reasonable depth below groundwater water. Scenario 4A simulated an average annual recharge rate of 4.2 MGD at the BWPCF and Scenario 4B an average recharge rate of 10 MGD. The scenarios assumed that the groundwater withdrawals are not recharged to the aquifer.

For these scenarios, fixed head values were simulated at locations along Route 28 and Bearses Way, shown in **Figure 35.** The fixed head values were adjusted at these locations until the groundwater elevations at sentinel points at St. Francis Circle Barnstable High School and the Cape Cod Mall matched the groundwater elevations determined as part of the steady-state capacity analysis. This allows for a depth to groundwater of greater than 8 feet under structures in these areas. The model computed flux at the fixed head locations is the estimated withdrawals required for each scenario. For the 4.2 MGD scenario, 4 wells would be installed along Route 28 and three along Bearses Way. For the 10 MGD scenario, 6 wells would be installed along Route 28 and 5 along Bearses Way.

Figure 35: Simulated Withdrawal Locations for 4.2 MGD Scenario [4A, left] and 10 MGD Scenario [4B, right]

The results indicate that 2.16 MGD would need to be withdrawn for Scenario 4A and 7.4 MGD for Scenario 4B. These results indicate that nearly all the additional flow beyond the steady-state site capacity of 2 MGD would need to be pumped and discharged far enough away from the BWPCF area to avoid water table impacts. Since the seasonal capacity of the site varies, higher withdrawal levels would be required in the late spring and following other periods of higher than normal background net recharge from precipitation. The magnitude of seasonally-driven and climatically-driven variations in withdrawals can be assessed with the transient groundwater model.

5.6 Scenario 5A/5B – Sea Level Rise Impacts

The impact of sea level rise on groundwater levels was evaluated with a steady-state USGS model containing a higher sea level and a revised freshwater-saltwater interface (USGS 2016), which represents 2 feet of sea level rise above sea levels in 2011 for central and western Cape Cod. The USGS study showed that under existing pumping and recharge conditions, a sea level rise of 2-feet will increase groundwater elevation beneath the BWPCF by approximately 0.8 feet (USGS 2016). Several updates were made to the USGS 2-foot sea level rise model in order to incorporate the findings of this Study:

- Hydraulic conductivity was updated in the vicinity of BWPCF to be consistent with changes made during model calibration.
- Pumping at public supply wells owned and operated by the Barnstable Fire District and Hyannis Water System was added using withdrawal rates in **Table 9.** The maximum withdrawal rate was attempted at each well, but at some locations, the maximum withdrawal rate caused the well to go dry. To prevent the model drying out near wells, withdrawal rates were reduced to 80 percent of the maximum rate at MH-1, MH-2, and MH-3, 70 percent of the maximum rate at MD-1, MD-2, MD-3, and MD-4, and 60 percent of the maximum rate at Airport-1. The pumping rates used for the sea level rise scenarios are nearly 4 times the long-term average pumping rates at these wells.

- No changes were made to model discretization.
- No changes were made to precipitation or return flow recharge.
- Recharge at BWPCF was applied as a fixed flux at different rates for each of the two scenarios:
  - Scenario 5A: Average annual recharge at 2 MGD to simulate seasonal site capacity; and
  - Scenario 5B: Average annual recharge at 6 MGD to simulate build-out flow at the BWPCF.

Using the 8 feet depth to water criteria, the steady-state model with 2 MGD of recharge at the BWPCF simulates a depth to water between 4 and 8 feet beneath one structure at St. Francis Circle and one structure near the Barnstable High School, shown on **Figure 36**. The groundwater table is lower in this sea level rise scenario than in the existing 2 MGD planning simulation (**Figure 30**) because of the increase in simulated withdrawals at nearby public water supply wells. The simulated pumping rates are nearly four times the rates used for the steady-state baseline and planning simulations. Differences in the simulations also exist due to the changes in the boundary conditions associated with the sea level rise and saltwater intrusion beneath the freshwater aquifer near the coastal boundary to the south.

When recharge is increased to the build-out flow at the BWCF (6 MGD), the model simulates depths to groundwater of less than 4 feet below structures near St. Francis Circle, Barnstable High School, Enterprise Road/Cape Cod Mall and near Fawcetts Pond (**Figure 37**).

Table 9: Town of Barnstable Hyannis Water System Current and Maximum Withdrawal Rates

Well	Long-term Average Rate (MGD)	Maximum Approved Withdrawal Rate (MGD)	Modeled Withdrawal Rate in Sea Level Rise Scenarios (MGD)

Section 6

Summary and Recommendations

Summary

Results of the study identified subsurface clay that limits the vertical movement of the groundwater. This clay is 5 to 20 feet thick and overlain on a dense sand. The dense sand has a low hydraulic conductivity so discharge of water through the clay would not likely be practical. Since the clay also limits vertical flow, subsurface discharge (groundwater injection) directly above the clay would not increase site capacity. The elevation of the clay varies which may direct flow locally.

Baseline simulations show that the mounding impacts from current average annual discharge rate of 1.6 MGD are large. Near St. Francis Circle, the BWPCF recharge increases the water table by 2 to 3 feet when compared to the zero recharge simulation. Mounding impacts of greater than 1-foot extend for over a mile radially from the site. Water levels in the aquifer respond over several months to changes in recharge, therefore, the transient nature of the system should be considered in order to fully maximize the potential recharge capacity.

Capacity is limited primarily by depth to water at low lying areas, particularly near St. Francis Circle. The site capacity varies depending on the amount of recharge from precipitation over the preceding three months. The estimated average annual site recharge capacity is 2 MGD but varies from a monthly average low of 0.96 MGD in April to as high as 3.1 MGD in August based on the hydrologic conditions from 2014 through 2018. (Scenario 1) The recharge rate for the BWPCF is currently at or near the site recharge capacity during the months of March through June.

Impacts to public water supply wells are greater than 5 years time of travel both in the transient conditions, based on the last five years of pumping and recharge, and steady-state conditions, with the higher seasonal capacity and permitted pumping rates at nearby wells. (Scenarios 2 and 3)

Withdrawal of water can reduce groundwater levels to acceptable levels off-site, however, nearly all water above the site capacity needs to be withdrawn. The feasibility of focused groundwater withdrawals was simulated using steady-state scenarios and should be reviewed in a transient simulation due to the 3-month lag in the response to changes in recharge. The simulation assumes that any water withdrawals will be discharged to the aquifer far enough from the site to prevent impacts to the water table. (Scenarios 4A and 4B)

In addition to coastal inundation, a sea level rise of 2-ft will increase the baseline groundwater elevations at the site by approximately 0.8 ft (USGS 2016). The simulations of sea level rise also included increased pumping at public water supply wells. Because of this increased pumping, steady-state simulations of recharge at the site based on the estimated site recharge capacity of 2 MGD did not show increases in the water table beneath structures. (Scenario 5A). The steady-state simulation of build-out conditions with a recharge rate of 6 MGD (Scenario 5B) showed areas with groundwater depth of less than 8 feet near St. Francis Circle, Barnstable High School, Enterprise Road/Cape Cod Mall and near Fawcetts Pond.

Recommendations

Based on the findings of this study, the following recommendations are being made:

- Use focused loading data and detailed depth to clay information to fine tune the model beneath the site and optimize bed loading. The elevation of the layer beneath beds 40 to 48 is high and it may be possible to take these beds off-line to allow for treatment plant expansion, if needed.
- Collect water level data at St. Francis Circle to evaluate the response in site bed loading rates, precipitation and groundwater levels. An off-site sentinel well which is not impacted by the BWPCF should be monitored to provide information on aquifer response to recharge from precipitation.
- Develop a predictive tool based on water levels in sentinel and downgradient wells, recorded precipitation and climate data (temperature) to estimate the actual recharge in the prior 3 months and site capacity.
- Optimize placement and pumping rates for focused feasibility withdrawals with steady-state and transient modeling. Determine the seasonal impacts to pumping withdrawals using the transient model and simulate the impacts from recharge of withdrawn water.
- Identify secondary loading sites for potential wastewater recharge. Evaluate the impact of recharge at the secondary loading sites including the additive impacts from the mounding due to the BWPCF recharge beds.
- Verify well depths and conduct downhole geophysics to identify clay layers at selected locations where data was unclear.
- Improve the simulation of lakes and ponds, particularly Wequaquet Lake, in the groundwater model using the Lake Package in MODFLOW. This will allow for simulation of the resistance of lake bed sediments to flow and simulation of water levels based on lake and pond bathymetry.
- The risks of increased effluent discharge at the BWPCF should be quantified.
- The groundwater flow model should be utilized to determine impacts to groundwater of potential effluent recharge sites.

SS	S-7	24/10		0.0	2 2 4 4		SW	(28-30') Wet, loose, light brown, coarse-medium-fine SAND, little fine gravel, trace coarse gravel.

EXPLANATION OF ABBREVIATIONS

DRILLING METHODS:
HSA - Hollow Stem Auger
SSA - Solid Stem Auger
HA - Hand Auger
AR - Air Rotary
DTR - Dual Tube Rotary
FR - Foam Rotary
MR - Mud Rotary
RC - Reverse Circulation
CT - Cable Tool
JET - Jetting
D - Driving
DTC - Drill Through Casing

SAMPLING TYPES:
AS - Auger/Grab Sample
CS - California Sampler
BX - 1.5" Rock Core
NX - 2.1" Rock Core
GP - Geoprobe
HP - Hydro Punch
SS - Split Spoon
ST - Shelby Tube
WS - Wash Sample
OTHER:
AGS - Above Ground Surface

REMARKS

BGS = Below Ground Surface
PID = Photoionization Detection
NA = Not Applicable
NM = Not Measured

Depth to water at 19-02 estimated based on water level at nearby pond on 6/28/19.

1.0 INTRODUCTION

This report details the results of an integrated geophysical investigation conducted by Hager GeoScience, Inc. (HGI) for CDM Smith (CDM) at the site of recharge beds at the Water Pollution Control Facility (WPCF) in Barnstable, Massachusetts.

The objective of the survey was to define the local stratigraphy, with focus on the evaluation of the presence and thickness of a clay layer.

2.0 DATA ACQUISITION

HGI performed all survey activities on July 11th and 12th, 2019. Plate 1, a base map created from the HGI field notes, grid marks, GPS, and Bing maps, shows the locations of the seismic and GPR surveys.

2.1 GPR Survey

HGI personnel used a Geophysical Survey Systems Inc. (GSSI) SIR-20 digital acquisition system and a multiple low frequency (MLF) high-powered antenna system operated at 35 MHz to collect data along 18 transects. The data were displayed on a color monitor for in-field quality control while being simultaneously recorded to the system's internal memory. The GPR data are recorded as two-way travel time and reflection amplitude, in which measurements are made of the time for the input radar wave pulse to reflect back to the antenna from a subsurface change in electrical properties, and the relative energy of the reflected signal.

Table 1 provides the data acquisition parameters used for the GPR data collection.

Table 1
GPR Data Acquisition Parameters

Antenna Frequency (MHz)	Range (ns)	Survey Mode	Scan Rate (per sec)	Scan Rate (per ft)	Sample Rate (samples)	Max. Effective Signal Depth (ft)
35 MHz	1400	Point	64	0.5	1024	20-120

Data from the GPR survey were downloaded to a PC at the HGI office for processing and analysis using GSSI's RADAN® 7 software.

2.2 MASW Survey

The MASW survey used both active and passive data collection methods to collect MASW data along 4 transects. The active method used a 90-pound propelled energy source (PEG) to generate a broadband frequency spectrum of surface waves. Lower frequency surface waves generated from various distal (passive) sources were also recorded using passive data collection techniques. Active and passive data sets were processed separately to produce dispersion images for each data

Copyright © 2019, Hager GeoScience, Inc. All rights reserved

set, with the separate dispersion images combined for analysis. Longer wavelengths associated with passive low-frequency energy can improve the depth resolution of MASW Vs modeling.

HGI personnel collected MASW data using a linear array of 4.5-Hz geophones. Seismic records were collected using a 24 channel array and a common offset "roll-along" and "streamer" data acquisition technique, where both the recording geophone array and source were advanced along the line by a specified distance until the total line length distance was reached.

Active records were collected in roll-along fashion, using 24 geophones, a 10-foot geophone spacing and a roll distance of 20 feet per shot. Passive records were collected for select active array configurations. Active data were acquired using a sampling interval of 1000 ms over a record length of 1 s. Passive data were sampled at 2 ms over a record length of 15 s. The expanded passive time window is designed to record arrivals of lower-frequency surface waves generated from natural sources (e.g., ocean waves).

For both active and passive data collection, geophone arrays were attached to HGI's Geometrics Geode® 24- or 48-channel exploration seismograph unit via a seismic cable that relays the motion-induced electrical signals from individual sensors to the seismograph.

Table 2 provides the data acquisition parameters used for the active MASW survey.

Table 2
Active MASW Survey Acquisition Parameters

Line	Source Offset (ft)	Number of Records	Station Spacing (ft)	Total Line Length (ft)	Sample Rate (ms)	Recording Time (sec)
1	20	29	10	790	1	1
2	20	31	10	840	1	1
3	20	20	10	630	1	1
4	20	46	10	1070	1	1

2.4 GPS Survey

HGI used its Sokkia RTK GRX2 GPS system to locate surface features and transects. Where an RTK solution was achieved, the Sokkia system provided a relative accuracy of less than 0.164 feet horizontally and 0.328 feet vertically. All points were recorded in the Massachusetts Cape and Islands State Plane 83F coordinate system. The data were later adjusted to National Spatial Reference System (NSRS) coordinates using the National Oceanic and Atmospheric Administration (NOAA) Online Positioning User Service (OPUS).

3.0 DATA REDUCTION AND ANALYSIS

Following the field data collection, the geophysical data were downloaded to a PC at the HGI office, where they were archived, processed, and analyzed using the following proprietary software:

- GPR analysis: GSSI's RADAN® 7
- MASW analysis: ParkSEIS© 3.0
- Graphic Presentations: Adobe Acrobat®, Golden Software© Surfer 12, AutoCAD® Map3D 2019, Microsoft© Excel

Section 5 provides a discussion of each method and its limitations.

3.1 GPR Survey

GPR data were processed and analyzed on HGI computers using GSSI's RADAN® 7 software. Prior to analysis, the raw GPR data required processing to reduce the detrimental effects of site-specific noise associated with interfering background frequency signals, destructive reflections from surface and buried objects, and general signal attenuation. Several iterations of GPR data processing and analysis were necessary to mitigate the detrimental effects and enhance the reflections associated with the clay layer.

GPR depths were calculated by converting two-way travel times to the GPR reflectors using radar propagation velocities estimated through reference to lookup tables of published values from GSSI and other sources, performing hyperbolic curve fitting when point reflectors were visible, and previous experience. Dielectric choice was further constrained by correlation with borehole data for the site provided by CDM Smith. Using borehole information from the log for monitoring well 19-01(b) a dielectric of 20 for undifferentiated sand and 50 for clay/silt was determined to be appropriate.

Annotated GPR records depicting interpreted subsurface features are provided as Figures G1 & G2, following the text.

3.2 MASW Survey

MASW survey data were analyzed using ParkSEIS© software and Excel®. ParkSEIS© was used to perform a surface-wave dispersion analysis for each shot gather, which was used to develop 1D Vs depth models representing the midpoint of each array position. The individual 1D Vs depth profiles were compiled to produce a 2D Vs depth profile.

In order to reduce the effects of an errant 1D Vs depth model among many 1D values across the site, the 1D Vs depth profiles are evaluated in context with one another as an interpolated model. This approach is supported by the concept that the geologic or anthropogenic processes responsible for the sediment distribution and, therefore, the Vs distribution, are a system of deposition definable by trend analysis. With this technique, the spatial characteristics of soil Vs reflect either

Copyright © 2019, Hager GeoScience, Inc. All rights reserved

the geologic or anthropogenic processes responsible for their distribution and are, therefore, more valid than values for any one single point.

Using this methodology, individual 1D profiles were compiled to form an XYZ matrix of distance, depth, and Vs values for each line. A 2D velocity model was then created from the matrix by grid interpolation using a kriging algorithm. The Vs trend analysis is represented as a 2D depth model visualized as a color-filled contour plot. Distances are expressed as feet from geophone 1.

4.0 RESULTS

The area of the Barnstable Water Pollution Control Facility (WPCF) is part of the "arm" of Cape Cod, which was primarily created by the Laurentide ice sheet during the Wisconsin glaciation. Interlobed glacial advance created the Sandwich moraine and glacio-deltaic outwash deposited sand, silt and clay into glacial Lake Nantucket Sound. During glacial re-advance and recession events, ice-thrusted sediments were eroded and re-deposited in the Barnstable Plain in glacial alluvial valleys, lakes and kettles.

Boring log 19-01(b) shows undifferentiated sands in the top 75 feet, followed by an approximately 10-foot-thick clay/silt layer above a fine grained sand. Cross sections provided by CDM Smith infer a clay/silt layer approximately 80 feet below ground surface. Both the GPR and MASW seismic survey results mapped a stratigraphic layer near these depths.

The results for the GPR and MASW surveys are shown in Figures 1 to 10, S1 to S4, and Plates 2 and 3. They show that the GPR and MASW results agree on the approximate depth of the top of the clay layer. The results for MASW lines 1 through 4 (Figures S1 to S4) show that the clay layer has a characteristic shear wave velocity (Vs) ranging from 900 to 1100 ft/sec, with the boundary between the upper coarse sand and the clay at a Vs of 1000 ft/sec.

An interpreted top and bottom of clay boundary is shown in each of the 10 GPR profiles (Figures 1-10). The bottom of clay is an inferred thickness based on an estimated GPR signal velocity for the clay. The depth to the top of the clay surface and clay thickness varies across the site, as. Figures 3 and G2 illustrate. The depth to clay over the entire survey area ranged from 55 to 107 feet below ground surface or 0 to -44 feet in elevation (NAVD 88). Clay thickness ranged from 5 to 20 feet.

Site-wide clay depth and elevation contour models were created by integrating the GPR and seismic data (Plates 2 and 3). Elevation data incorporated into the site elevation model were taken from HGI's GPS data, which is not a comprehensive site elevation survey.

The contour plots show trends in clay layer depth and elevation, including localized areas where the clay elevation is low. Areas of higher clay elevation may channel water toward lower elevations as water migrates along the top of the relatively impermeable clay layer, providing a preferential pathway for groundwater flow beneath the site.

5.0 THE GEOPHYSICAL METHODS

5.1 Ground Penetrating Radar (GPR)

5.1.1 Description of the Method. The principle of ground penetrating radar (GPR) is the same as that used by police radar, except that GPR transmits electromagnetic energy into the ground. The energy is reflected back to the surface from interfaces between materials with contrasting electrical (dielectric and conductivity) and physical properties. The greater the contrast between two materials in the subsurface, the stronger the reflection observed on the GPR record. The depth of GPR signal penetration depends on the properties of the subsurface materials and the frequency of the antenna used to collect radar data. Lower frequency antennas provide greater signal penetration, but result in lower object resolution.

5.1.2 Data Collection. HGI collects GPR data using a Geophysical Survey Systems (GSSI) SIR 20 ground penetrating radar system. Data are digitally recorded on the internal hard drive of the GPR system. System controls allow the GPR operator to filter out noise, attributed to coupling noise caused by conductive soil conditions, spurious noise caused by local EMF fields, and internal system noise. For shallow surveys, we use antennas with center frequencies ranging from 2000- to 400-megahertz (MHz). For deeper penetration, we use lower frequency antennas ranging from 350 MHz to 15 MHz, depending on the anticipated target depth and the degree of signal penetration. All of these antenna configurations can collect data in continuous mode, distance mode, or as discrete point measurements using signal-stacking techniques. Since there is a trade-off between signal penetration and resolution, test data are sometimes collected using antennas with several different frequencies, with the highest frequency antenna that produces the highest quality data used. In some cases, data are collected with several antenna frequencies.

The horizontal scale of the GPR record shows distance along the survey traverse. In the continuous data collection mode, the horizontal scale on each GPR record is determined by the antenna speed along the surface. When a survey wheel is used, the GPR system records data with a fixed number of traces per unit distance. The GPR record is automatically marked at specified distance intervals along the survey line. The vertical scale of the radar record is determined by the velocity of the transmitted signal in the media under study and the range setting, or recording time window of the GPR system. The recording time interval, or range, represents the maximum two-way travel time in which data are recorded. The conversion of the two-way travel time of the transmitted signals to depth is determined by the propagation velocity of the GPR signal, which is site (media) specific. When little or no information is available about the makeup of subsurface materials, we estimate propagation velocities from handbook values and experience at similar sites or by CDP velocity surveys with a bi-static antenna.

5.1.3 Data Processing. After completion of data collection, the GPR data are transferred to a PC for review and processing using RADAN® 7 software. When appropriate, we prepare 3D models of GPR data, which can be sliced in the X, Y, and Z directions.

The size, shape, and amplitude of GPR reflections are used to interpret GPR data. Objects such as metallic UST's and utilities produce reflections with high amplitude and distinctive hyperbolic

Copyright © 2019, Hager GeoScience, Inc. All rights reserved

shapes. Clay, concrete pipes, boulders and other in-situ features may produce radar signatures of similar shape but lower amplitude. The boundaries between saturated and unsaturated materials such as sand and clay, bedrock and overburden, generally also produce strong reflections.

5.1.4 Limitations of the Method. GPR signal penetration is site-specific and is determined by the dielectric properties of local soil and fill materials. GPR signals propagate well in resistive materials such as sand and gravel; however, soils containing clay, ash- or cinder-laden fill or fill saturated with brackish or otherwise electrically conductive groundwater cause GPR signal attenuation and loss of target resolution. Concrete containing rebar or wire mesh also inhibits signal penetration.

The interpreted depths of objects detected using GPR are based on on-site calibration, handbook values, and/or estimated GPR signal propagation velocities from similar sites. GPR velocities and depth estimates may vary if the medium under investigation or soil water content is not uniform throughout the site.

The MLF GPR antenna is unshielded and produces a signal pattern that emanates in all directions from the antenna. Therefore, objects may be detected before the antenna is located directly over them. GPR anomalies may appear larger than actual target dimensions.

GPR interpretation is more subjective than other geophysical methods. The interpretive method is based on the identification of reflection patterns that do not uniquely identify a subsurface target. Borings, test pits, site utility plans and other ground-truth are recommended to verify the interpreted GPR results.

5.2 Multi-Channel Analysis of Surface Waves (MASW)

5.2.1 Description of the Method. The multi-channel analysis of surface waves (MASW) method uses the dispersion analysis of Rayleigh-type surface waves to extract a shear wave velocity depth profile. A 2D shear wave velocity field accurate to within 15% can be produced by acquiring many individual multi-channel surface wave data gathers and inverting the surface wave dispersion curves to form a series of 1D shear wave profiles. Discrete individual cells that make up the shear wave velocity field provide a measure of resolution potential and are dependent on the frequency range of the data and source spacing. Variations in the shear wave velocity field representative of an anomalous subsurface can easily be interpreted on shear wave velocity field contours. As generally applied, the method focuses on surface wave energy with frequencies ranging from 2 to over 60 Hz (frequency and associated wavelengths are indicative of depth of investigation) and is relatively insensitive to cultural noise and surface conditions (e.g., asphalt, grass, gravel, mud, etc.). By incorporating common mid-point (CMP)-style roll-along acquisition (seismic reflection method) with multi-channel acquisition, sufficient redundancy and resolution exist to interpret anomalies evident across several 1D profiles.[1] The MASW method can use both active and passive sources to generate surface waves.

[1] Miller, R.D., Xia, J., Park, C.B., and Ivanov, J., 2000. Shear wave velocity field from surface waves to detect anomalies in the subsurface: Proceedings of the First International Conference on the Application of Geophysical Methodologies to Transportation Facilities and Infrastructure, St. Louis, Dec. 11-15.

Copyright © 2019, Hager GeoScience, Inc. All rights reserved

Advantages of using the shear wave velocity field (calculated from surface waves) to detect, delineate, and/or map anomalous subsurface materials include the insensitivity of MASW to velocity inversions and cultural noise, ease of generating and propagating surface wave energy in comparison to body wave energy, and its sensitivity to changes in velocity. Compression-wave velocity (V_p) is one of the valuable by-products obtainable from the same data set used for shear wave (V_s) analysis through a different processing step. Standard processing routines are available to enhance record quality prior to the analysis.

5.2.2 Data Collection. We collect seismic data using our Geometrics Geode© exploration seismograph system with 24- or 48-channel geophone arrays and 4.5-Hz OYO geophones/receivers mounted on a land-streamer system. Geophone spacing depends on the depth of investigation, but is between 5 to 30 feet.

For active seismic source surveys, energy is generated by ramming a steel plate with a 90-pound propelled energy generator (PEG-40Kg) or with a Betsy seisgun that uses 8- or 12-gauge industrial blanks to create an airwave. The quality of the seismic signal for each shot point is verified in the field. The seismograph records all seismic data to an internal hard drive and floppy disk, from which it is transferred to a PC.

5.2.3 Data Analysis and Interpretation. Data reduction and analysis of MASW data are performed using ParkSEIS® software. Data reduction and analysis begin with the consolidation and reformatting of individual shot gathers for each line into a single multi-record file format. The survey geometry is defined for each seismic record. Dispersion curve analysis is then performed for each shot gather in the multi-record file by examining the change in phase velocity vs. frequency using the fundamental mode component of the dispersion data. Non-linear in version modeling of each dispersion curve is performed and results in a 1D mid-point representation of V_s and V_p depth profiles. Interpolation of the 1D data using a kriging algorithm produces a 2D grid of the V_s data. Color-filled contour profile plots are then generated from the V_s grid.

5.2.4 Limitations of the Method. Site-specific testing is required to evaluate background noise levels, to demonstrate the recording of meaningful surface wave data, and to estimate signal-to-noise (S-N) values. Acquisition parameters, such as receiver/shot coupling, shot offset, receiver spacing, sampling rate, record length, and other parameters are also site-specific. For records exhibiting low S-N levels, shots must be added to stack the coherent parts of the signal, which helps mitigate the detrimental effects of random environmental noise.

The MASW and other surface wave methods are primarily designed to obtain Vs of lower velocity soils (relative to high velocity bedrock). Because of the high seismic velocities of most rock types, significantly longer geophone arrays than space allows are required to measure Raleigh wave dispersion in rock.

Copyright © 2019, Hager GeoScience, Inc. All rights reserved

5.3 RTK GNSS Global Positioning System (GPS)

5.3.1 Description of the Method. The RTK GPS system consists of a base (reference) receiver and a roving receiver. The base receiver remains stationary during a survey and is mounted on a tribrach and tripod. A rover receiver is used to record points remotely and can be mounted on a staff, vehicle, or other object. The base provides real-time corrections to the rover over a radio connection. The system can produce accuracy on a centimeter scale, but the level of accuracy depends on factors that include the geometry of the transmitting satellites and the receivers' view of the horizons (e.g., the density of buildings and trees). The data can be collected as quickly as 1 Hz or 1 reading per second.

5.3.2 Data Collection and Processing. We perform our GPS surveys using a Sokkia RTK GRX2 GPS system. The base station can be set up over a known or unknown point, with the position taken from satellite information. Once the system has achieved a fixed solution for the rover receiver, data points can be collected with survey-grade (centimeter-scale) precision. When GPS points are being collected at a site where the fixed solution is constantly lost and gained, points are checked multiple times for precision. All data points are saved to an Allegro CX field computer.

The GPS data are corrected automatically by the base receiver in the field prior to being recorded. If the base station is located on an unknown point that is later defined, the GPS data can be corrected in the office to fit the real world coordinates.

5.3.3 Limitations of the Method. The quality of the GPS signal is site-specific. The base and rover receiver need to have clear views of the horizon and good satellite geometry to achieve the highest level of accuracy and precision. Although a fixed solution can be achieved in wooded environments or sites with taller buildings, it may take more time to achieve the solutions, the fixed solution may be lost frequently when moving the rover, and in some cases the fixed solution may be wrong. Each of these situations requires longer to locate data points accurately and precisely. When the point is too close to a building, beneath a building overhang, under a tree, or obscured by some other object, a fixed solution may not be possible.

When the base station is set up over an unknown point, the survey data location can be at least several tens of meters from the real world location. The data points will have survey grade precision relative to the location of the base station and other data points, but will have a real world accuracy discrepancy.

HGI does not guarantee to produce a surveyor-quality map from its GPS data, as this is not its profession. If survey-level accuracy is critical for a project, we recommend hiring professional surveyors for that purpose.

Figure G1
Clay Boundary Radargrams
GPR Transects 9 and 10

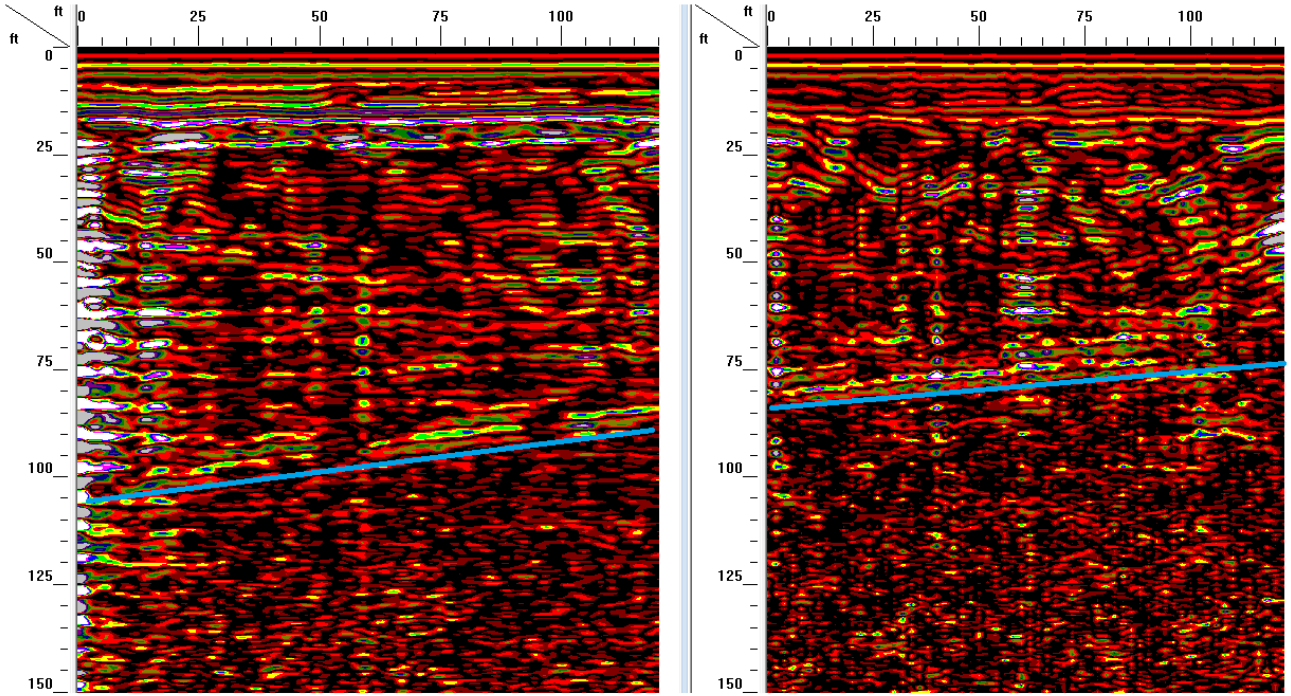

Figure G1. The above radargrams show the boundary between undifferentiated sand and the top of clay/silt. The boundary between the two units is annotated in blue.

Figure G2
Clay Thickness Radargrams
GPR Transects 3 and 4

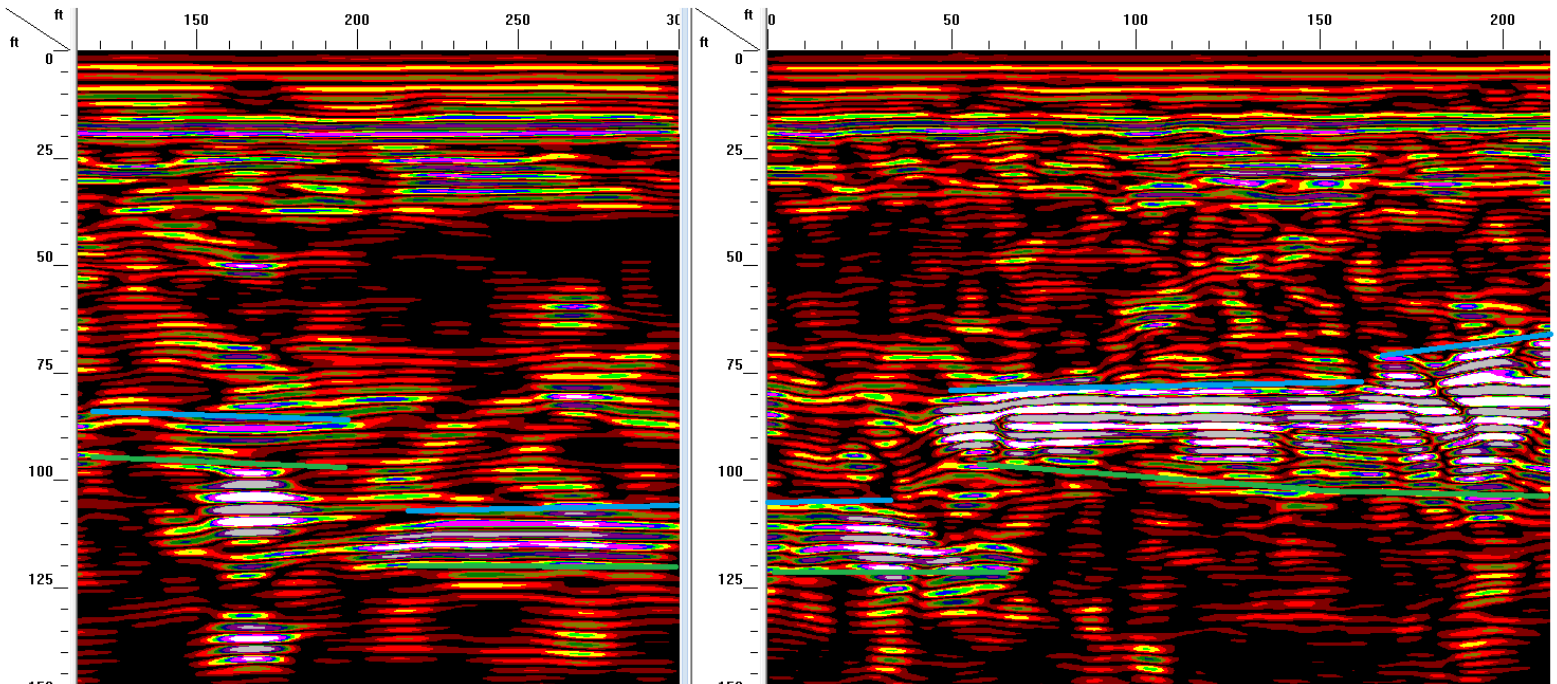

Figure G2. The above radargrams are examples of clay thickness estimations. The interpreted top of clay is highlighted in blue and the bottom of clay is highlighted in green.

Effluent Outfall Preliminary Feasibility Review

WRIGHT-PIERCE
Engineering a Better Environment

MEMORANDUM

TO:	Griffin Beaudoin – Town of Barnstable	**DATE:**	10/23/2020
FROM:	Neil Cheseldine, Ed Leonard	**PROJECT NO.:**	20157B
SUBJECT:	Barnstable CWMP – Effluent Outfall Preliminary Feasibility Review		

INTRODUCTION

As a part of its Comprehensive Wastewater Management Plan (CWMP), the Town is interested in conducting a "desktop" preliminary feasibility review of an ocean outfall in order to supplement the existing effluent disposal capacity. The preliminary candidate locations for an ocean outfall are Nantucket Sound, Cape Cod Bay and the Cape Cod Canal. There are many tasks required in order to successfully site an ocean outfall in accordance with the Massachusetts Ocean Sanctuaries Act (MGL Ch.132A, Sec.16G). This initial assignment is preliminary in nature and intended to identify the general vicinity where an effluent outfall could potentially be sited based on physical parameters and other general considerations.

PLANNING SCENARIOS

The Town of Barnstable is one of the largest Towns in Massachusetts and consists of seven distinct villages. The Town owns, operates and maintains a municipal wastewater collection and treatment system for its downtown and other areas of town. The Town has approximately 55 miles of sewer piping and 27 pumping stations (with one being constructed) and collects flows from approximately 2,300 acres of land area.

The Barnstable Water Pollution Control Facility (WPCF) includes septage handling, pretreatment, primary treatment, secondary treatment with nitrogen removal, disinfection, rapid infiltration basin disposal facilities, and solids processing. The WPCF has a current maximum daily discharge limitation of 2.70 million gallons per day (mgd) and a treatment capacity of 4.20-mgd at maximum daily flow. From 2013 to 2018, the WPCF has treated an annual average flow of 1.55-mgd and a maximum-month flow of 1.93-mgd.

Based on the CWMP, a significant increase in the number of sewered properties will be required to address water quality concerns in sensitive embayments that are adversely impacted by groundwater nitrogen loadings. As a part of the CWMP, the Town has been actively working on regional approaches to solve its water quality problems in order to determine if there are cost savings and environmental benefits. Potential regional approaches include: 1) working with Yarmouth; 2) working with Sandwich/Mashpee; and/or 3) working with all of the Upper Cape towns at Joint Base Cape Cod (JBCC).

The Town identified three potential flow scenarios for consideration in this review:

1) Barnstable CWMP: Total flow of 4.5-mgd annual average flow with **2.5-mgd** going to the ocean outfall and 2.0-mgd going to the existing land-based disposal system at the Barnstable WPCF site.
2) Barnstable CWMP plus the "Yarmouth Lewis Bay Scenario": Total flow of 5.0-mgd annual average flow with **3.0-mgd** going to the ocean outfall and 2.0-mgd going to land-based disposal system at the Barnstable WPCF site.
3) Barnstable CWMP plus the "Yarmouth Lewis Bay Scenario" plus the "Sandwich/Mashpee Three Town Regional Scenario": Total flow of 5.54-mgd annual average flow with **3.54-mgd** going to the ocean outfall and 2.0-mgd going to the land-based disposal system at the Barnstable WPCF.

A description of the Yarmouth Lewis Bay Scenario and the Sandwich/Mashpee This evaluation purposely omitted the "logistics" associated with transport/treatment and focused solely on effluent disposal. Three Town Regional Scenario are beyond the scope of this memorandum. We will utilize 3.54-mgd average daily flow as the basis for this preliminary feasibility review.

BASIS FOR FLOWS

Different components of a wastewater system are designed based on different process conditions (e.g., minimum day, annual average, maximum month, maximum multi-day, maximum day and peak instantaneous, etc.). For the purposes of this study, we established sewage peaking factors using the TR-16 Guides for the Design of Wastewater Treatment Works curves entitled "Relation of Extreme Discharges on Maximum and Minimum Days to the Average Daily Discharge of Domestic Sewage" (New England Interstate Water Pollution Control Commission, 2016) and the maximum month, maximum day and peak instantaneous values were adjusted upward by 0.2 to account for unique seasonal population/flow variations on Cape Cod. **Table 1** summarizes the peaking factors which have been used for this project as well as the flow rates for the various process conditions.

TABLE 1 - PEAKING FACTORS AND EFFLUENT FLOWS

Condition	Peaking Factor (Ratio from Annual Average)			Flow
	TR-16	Seasonal Adj.	Peak Factor	
Minimum Day	0.50	0.0	0.50	1.7-mgd
Minimum Month	0.75	0.0	0.75	2.6-mgd
Annual Average	1.0	0.0	1.00	3.54-mgd
Maximum Month	1.25	0.2	1.45	5.1-mgd
Maximum Day	1.9	0.2	2.10	7.4-mgd
Peak Instantaneous	3.0	0.2	3.20	11.3-mgd

POTENTIAL RECEIVING WATERS

Three potential receiving waters have been identified: Nantucket Sound, Cape Cod Bay and the Cape Cod Canal. Based on a review of National Pollutant Discharge Elimination System (NPDES) permits issued by EPA for ocean outfalls for facilities of similar size in Massachusetts and Maine, the minimum off shore distance was set at 3,000 feet for this analysis. Each are described below.

Nantucket Sound

Nantucket Sound off-shore waters are designated as a Class SA waterway by the DEP (SWQ Standards), not designated as an Outstanding Resource Water, and not designated as an Area of Critical Environmental Concern. Numerous tidal estuaries and embayments in Nantucket Sound are designated as an Outstanding Resource Water but we have limited our potential outfall location consideration to areas that are at least 3,000 feet off shore. Nantucket Sound is located within the Cape and Islands Ocean Sanctuary as designated under the Massachusetts Ocean Sanctuaries Act (M.G.L. c. 132A, 301 CMR 27.00). It provides habitat to a number of sensitive and/or endangered species including five species of turtles (Loggerhead, Leatherback, Kemp's Ridley, Green and Hawkbill), numerous whale species including endangered North Atlantic Right Whales, and several species of seals and porpoises including the gray seal, harbor seal and harbor porpoise.

Cape Cod Bay

Cape Cod Bay off-shore waters are designated as a Class SA waterway by the DEP (SWQ Standards), not designated as an Outstanding Resource Water, and not designated as an Area of Critical Environmental Concern. Similar to Nantucket Sound, numerous near shore waters (including Barnstable Harbor) are designated as Outstanding Resource Waters, but areas we considered for potential outfall locations were at least 3,000 feet off shore. The Cape Cod Bay area of interest is located within the Cape Cod Bay Ocean Sanctuary per the Ocean Sanctuaries Act. The entire north coast of the Town of Barnstable on Cape Cod Bay is within the Sandy Neck Barrier Beach System, which is designated as an Area of Critical Environmental Concern. The area includes Significant Resource Areas (SRAs) in the Massachusetts Coastal Zone Management (CZM) program. This area encompasses a 7-mile barrier beach, several thousand acres of salt marsh, productive shellfish beds and numerous other sensitive environmental resources. A new or increased discharge to an Outstanding Resource Water is prohibited unless it is necessary to accommodate important and economic or social development, no less environmentally damaging alternative site is reasonably available or feasible, and the discharge is designed to minimize adverse water quality impacts and still meet all criteria for the class. Therefore, we would not include this area for consideration of a new outfall unless all other areas are found not feasible. We also anticipate that crossing this area for installation of a new outfall would be challenging from an environmental permitting perspective, so it may be preferable to consider locations near the Barnstable/Sandwich town boundary or the Barnstable/Yarmouth town boundary to limit the impact to the ACEC zone. The majority of the targeted off-shore area (i.e. beyond 3,000 feet off shore) meet the target depth of greater than 40 feet, so relocation of the potential outfall location in Cape Cod Bay is feasible. Since the ACEC zone extends across the entire north shore of the

Town, it might be necessary to install some of the over land outfall piping outside of the Town of Barnstable in either Sandwich or Yarmouth.

The Cape Cod Bay is habitat to sensitive and/or endangered species including the North Atlantic Right Whale, Humpback Whale, Roseate Tern and Piping Plover. The shoreline provides habitat for other sensitive species, which would need to be addressed and accommodated in the construction of a new outfall but would not be expected to be impacted by the operation of a new ocean outfall.

The Cape Cod Bay is subject to strong tides that move water in and out of the bay exchanging about 9.3% of the total bay water volume and maintaining a well-mixed marine environment. The larger Gulf of Maine system is generally subject to counterclockwise currents influenced by a number of systems including the Gulf Stream, Labrador Current, Eastern Maine Coastal Current (EMCC) and Western Maine Coastal Current (WMCC). Hydrodynamics of the Bay are also influenced by the Cape Cod Canal with a net westward flow out of Cape Cod Bay to Buzzards Bay of approximately 3 billion gallons per tide change.

Cape Cod Canal

The Cape Cod Canal is designated as a Class SB waterway by the DEP (SWQ Standards), is not designated as an Outstanding Resource Water and is not an Area of Critical Environmental Concern. The Canal is a man-made waterbody that interconnects Buzzards Bay (west side) and Cape Cod Bay (east side) which is managed and operated by the Army Corps of Engineers (ACOE). It is a trapezoidal land cut that is approximately 700 feet wide at the top and approximately 500 feet wide at bottom with 3:1 riprap side-slopes. The land cut is approximately 6.9 nautical miles long from the Sandwich beach entrance to the Massachusetts Maritime Academy docks. The ACOE Navigation Channel dimensions are 480 feet minimum wide and 32 feet minimum deep envelope below mean low-low water. Channel depth minimum dimensions are maintained by periodic dredging.

The flow of seawater in the Canal is governed by the tide water levels in Buzzards Bay and Cape Cod Bay. Each bay's tidal water levels are governed by different branches of the main cyclic tidal wave in the Atlantic Ocean. When the head on the Cape Cod Bay side is higher than the Buzzards Bay side the flow is from east to the west, called the ebb. When the head on the Buzzard Bay side is higher, the flow is from west to east and is the flood tide. The driving head is also impacted by storm and wind factors. The flow reverses direction about every 6.2 hours with the shift in water surface profile. As outlined in the EPA 1981 Draft Environmental Impact Statement (EIS), the Canal volume is an estimated 8.5 billion gallons. The westward tidal flow totals an estimated 22 billion gallons per tide change and the eastward flow totals an estimated 19 billion gallons per tide change. The Draft EIS indicates that the hydrodynamics for the Cape Cod Bay end of the Canal are relatively straight-forward but that the hydrodynamics associated with Buzzards Bay are relatively complex.

Wright-Pierce previously completed a preliminary feasibility evaluation of a new outfall in the Cape Cod Canal (May 17, 2019). Based on this evaluation, it was concluded that it is potentially

feasible to install a new outfall in the Cape Cod Canal for 13.5-mgd annual average flow, with a 100 foot long diffuser in 40 feet of water within 200 feet of shore, and achieve a minimum dilution factor of 50:1 during slack tide minimum current velocity conditions.

POTENTIAL OUTFALLS TO SURFACE WATER

Any new effluent discharge to surface water in Massachusetts must meet the requirements of Massachusetts Ocean Sanctuaries Act MGL Ch.132A, Sec.16G (OSA).The OSA requires that the following 10 items must be met (*italics indicate text from MGL*):

1) *The new or modified discharge shall be consistent with the intent and purpose of the act. Any discharge shall meet the water quality standards of the receiving water body and the standards of the act to protect the appearance, ecology, and marine resources of the waters of the sanctuary.*
2) *The new or modified discharge shall meet the United States Environmental Protection Agency's approved TMDL, if any, on the receiving water body.*
3) *The applicant shall have adopted and implemented a plan approved by the department requiring the pretreatment of all commercial and industrial wastes discharged to the POTW.*
4) *The applicant shall have adopted and implemented a program for water conservation according to the guidelines established by the water resources commission.*
5) *The applicant shall have adopted and implemented a plan, approved by the department, to control and minimize inflow and infiltration.*
6) *The applicant shall have adopted and implemented a plan, approved by the department, to control any combined sewer overflows.*
7) *The new or modified discharge shall not significantly affect the quality or quantity of existing or proposed water supplies by reducing ground or surface water replenishment.*
8) *The new or modified discharge is consistent with the policies and plans of the Massachusetts coastal zone management program.*
9) *The new or modified discharge and treatment plans are consistent with all applicable federal, state, and local laws, ordinances, by-laws, rules, and regulations protecting the environment, including but not limited to, the requirements of chapters 21, 91, 130, and 131.*
10) *The proposed discharge and outfall structure will not adversely impact marine fisheries or interfere with fishing grounds or the normal operation of fishing vessels.*

The OSA Regulations stipulate that an application for a new or modified discharge must include the following *(italics indicate text from 301 CMR 27.00)*:

1) *The Department's application form for a new or modified discharge to an ocean sanctuary.*
2) *A description, coordinates, and maps of the proposed modified or new discharge, including location(s), average daily flow, proposed level of treatment, design capacity, existing and proposed outfall locations and alignment of discharge pipes and other related structures, a summary of any proposed changes to existing discharge conditions, effluent quality or*

characteristics. Maps shall show the boundaries of the affected ocean sanctuary and demarcate the following: Areas of Critical Environmental Concern; Special, Sensitive or Unique Resources from the Ocean Management Plan; marine life and natural resources, including but not limited to wetland resource areas, shellfish beds, eelgrass beds, habitats of endangered and threatened species, species of special concern; fisheries resources, including but not limited to commercial and recreational fishing areas, spawning sites, nursery and forage areas, and migratory pathways or areas necessary for other functions or critical stages in the life cycle of economically or recreationally important species; Concentrations of Water Dependent Uses from the Ocean Management Plan; recreational resources including, but not limited to, bathing beaches, boating areas and scenic areas; and water quality classification(s) of affected waters.

3) *A final CWMP, targeted watershed management plan, or other appropriate substitute as may be required, and has been approved by the department.*
4) *A final environmental impact report and certificate with the Secretary's findings and determinations.*
5) *A detailed evaluation of the receiving water body, including the data, information, results and conclusions from the following surveys and investigations establishing, at a minimum, a two year baseline: Ocean Sanctuaries Act Regulations Revisions: Final Version 9 (a) water quality monitoring, including nutrients, temperature, pH, dissolved oxygen, water clarity; (b) fisheries survey, including finfish and shellfish; (c) benthic sediments and infauna; and (d) fisheries habitat including eelgrass.*
6) *Data, information, results and conclusions from the development of a site-specific hydrodynamic model illustrating tides, bathymetry, mixing zones and seasonal variations that estimate dilution and dispersion of nutrients, pathogens, and other relevant contaminants within the wastewater discharge.*
7) *A hydrologic evaluation of any affected aquifer(s), including evaluation of the effects of the new or modified discharge, and any planned and potential sewering, on the recharge of the affected aquifer, and how those changes may affect drinking water supplies or natural resources.*
8) *An evaluation of the commercial and recreational fisheries at the project site, in the embayment and estuary, and in the affected ocean sanctuary, including the specific existing and potential fisheries, and the value of the fisheries. The evaluation must include an analysis of potential closures due to public health requirements including the potential extent of the mandatory shellfish bed closures to meet prescribed standards in the U.S. Food and Drug Administration's National Shellfish Sanitation Program Guide for the Control of Molluscan Shellfish. The evaluation shall also include potential impacts from the proposed outfall structure on normal operation of fishing vessels or equipment.*
9) *A proposed long-term monitoring plan to document that any new or modified discharge would continue to meet the intent of the Act, the standards of 301 CMR 27.07(3), and other applicable laws and regulations.*
10) *Documentation, detailed analysis, and supporting evidence demonstrating how the new or modified discharge meets the requirements and standards in 301 CMR 27.07(3).*

If the above can be met, then a surface water discharge could be permitted by the Environmental Protection Agency (EPA) and the Massachusetts Department of Environmental Protection (DEP). The Barnstable WPCF effluent discharge would need to meet permit limits set forth in a new National Pollutant Discharge Elimination System (NPDES) permit issued by the EPA in accordance with Section 402 of the Clean Water Act. The Barnstable WPCF would also need to continue to meet the permit limits set forth in its existing (or future modified) DEP Groundwater Discharge Permit.

Table 2 summarizes the anticipated effluent limits for discharge into SA and SB marine waters, based on the current permitting approaches used by EPA and DEP. Table 2 also summarizes the current Groundwater Discharge Permit limits for the Barnstable WPCF. The Barnstable WPCF would require upgrades to achieve the anticipated NPDES permit limits.

TABLE 2 - ANTICIPATED WPCF PERMIT LIMITS

Parameter	**GWDP Existing Limits Rapid Infiltration [(1)]**	**NPDES Anticipated Limits Outfall (Class SA)**	**NPDES Anticipated Limits Outfall (Class SB)**
BOD_5, mg/l	30	30	30
TSS, mg/l	30	30	30
Total Dissolved Solids, mg/l	1,000	n/a	n/a
Total Nitrogen, mg/l	10 [(2)]	3 [(3)]	3 [(3)]
Nitrate-Nitrogen, mg/l	10	n/a	n/a
Ammonia-Nitrogen, mg/l	n/a	n/a[(4)]	n/a[(4)]
Oil & Grease, mg/l	15	n/a	n/a
Fecal Coliform (geo mean), #/100 ml	200	14	88
Enterococci (geo mean), #/100 ml	n/a	35	35
Total Residual Chorine, mg/l	1	0.65 [(5)]	0.65 [(5)]
Total Recoverable Metals, mg/l	n/a	n/a [(4)]	n/a [(4)]
Total Phosphorus, mg/l	n/a	n/a	n/a
Total Organic Carbon, mg/l	n/a	n/a	n/a
Turbidity, NTU	n/a	n/a	n/a
Virus Removal, log removal	n/a	n/a	n/a

Notes:
1.) GWD Permit #21-1.
2.) TN not to exceed 49,315 lbs per calendar year (equivalent to 6 mg/l at 2.7 mgd)
3.) Presumed based on input from EPA and Buzzards Bay Coalition.

4.) Assume dilution factors of greater than 50:1 can be obtained which would preclude the need for metals or other toxics limits. Ammonia limits not needed since TN limit governs.
5.) Max day limit based on acute criteria of 13 ug/l and 50:1 acute dilution. Not applicable if ultraviolet disinfection implemented.

MIXING, DILUTION AND DESIGN CONSIDERATIONS

The DEP Implementation Policy for Mixing Zone (January 1993) defines how a mixing zone is established for a surface water outfall. A "mixing zone" is an area or volume of a waterbody in the immediate vicinity of a discharge where the initial dilution of the discharge occurs. This mixing zone is also called a Zone of Initial Dilution (ZID) where dilution is rapid, driven by the intentionally high velocity and momentum of the effluent discharge. Within a mixing zone, excursions from certain water quality criteria may be tolerable, provided this does not interfere with the existing or designated uses of the segment. Water quality criteria apply at the boundary of the mixing zone. The mixing zone is a function of the proposed outfall flow rate versus the minimum flow or current velocity of the receiving water. In the case where there is tidal flow, there is a significant amount of judgement used by the permit writer in calculating the appropriate dilution factor and sizing the mixing zone.

EPA has established ambient water quality standards which indicate the maximum concentration limits which are protective of aquatic life for both short-term (acute) exposure and long-term (chronic) exposure. WWTF effluent is allowed to be thoroughly mixed with receiving water to dilute the concentrations to below acute water quality standards within the Zone of Initial Dilution. However, the mixing and resulting dilution must occur as fast as possible and in as small an area as possible. Mixing zones are limited in size as defined in the regulations. At the outer boundary of the acute mixing zone, the effluent must be sufficiently diluted to meet the acute water quality criteria. Mixing zones must be small enough to allow free passageways for aquatic life to bypass the zone. According to the EPA *Technical Support Document for Water Quality-Based Toxics Control*, organisms are not to be exposed to concentrations greater than the acute criteria when concentrations are time-weighted over one hour of exposure time in the plume.

There is also a secondary mixing zone for chronic water quality criteria, that is larger than the initial acute mixing zone, where dilution processes are much slower than the acute mixing zone. In the chronic zone, dilution occurs by wind driven waves and currents and concentration dispersion. Chronic zone dilution requires computer models to estimate the dilution and size of the mixing zone. Detailed hydraulic and hydrodynamic modeling is needed to provide more refined results (e.g., computational fluid dynamics, CORMIX, Visual Plumes/ UM3).

For this preliminary feasibility and planning study, we performed simplified spreadsheet analysis for various diffuser lengths and design current velocities. For each trial, the cross-sectional area of the water above the diffusers (length of diffuser section times water depth) was calculated and then multiplied by the velocity to calculate the bulk receiving water flow. The ZID dilution factor was then calculated by dividing the sum of the receiving water and WWTF flows by the WWTF flow. This dilution factor is used for comparison to the acute water quality criteria.

The most significant variables that influence dilution of an ocean outfall are diffuser depth and current velocity. Near shore ocean currents are most often dominated by tidal dynamics resulting in reversing currents. For outfall design, the most conservative design condition is the average current velocity that occur immediately before and after slack tide. This particular current condition is not commonly included in most publicly available ocean current studies and can vary widely based on numerous factors including bathymetric conditions around the outfall. Therefore, site-specific current monitoring would be required prior to final design of a new outfall. For this evaluation, we have assumed conservatively low design current speeds based on a review of outfall evaluations and designs at other similar locations including Marshfield, MA NPDES permit (0.05 f/s) and Sanford Sewerage District, Sanford, ME outfall evaluation study (0.033 f/s). The following physical parameters and assumptions were used in our potential site identification and simple dilution evaluation:

- Target water depth: 40 feet
- Current Velocity Design Basis:
  - Minimum (acute dilution): 0.033 ft/sec (slack tide conditions)
  - Average (low): 0.33 ft/sec
  - Average (normal): 1.0 ft/sec
- The use of multi-port diffusers oriented perpendicular to receiving water flow, with a discharge velocity of approximately 10 fps per port, in order to maximize dispersion and mixing of effluent with the receiving water. Alternating at 45 degrees either side of vertical and 10-foot spacing (20-foot on each side).

The Cape Cod Bay waters are consistently deeper than 40 feet beyond 3,000 feet off-shore. The Nantucket Sound waters are much shallower in the near-shore area; waters with greater than 40 foot depth are at least 12,000 feet off-shore. Approximate outfall locations are designated on Figure 1 with red rectangles. These locations were selected using publicly available bathymetric data and based on the target water depth noted above and a minimum off-shore distance of 3,000 feet. The potential locations are summarized as follows:

- Cape Cod Bay:
  - Approximately 40 foot depth and 3,500 to 4,000 feet off shore
  - Extensive area at the target depth to install outfall diffuser section
- Nantucket Sound:
  - Approximately 38 to 40 foot depth and 12,000 to 15,000 feet off shore
  - Two small areas at the target depth to install outfall diffuser section (~200 feet x 150 feet and 400 feet x 1200 feet)
- Cape Cod Canal:
  - Approximately 40 foot depth and 200 feet off shore
  - Small area at target depth beneath the Army Corps of Engineers navigation channel

None of these locations have any published TMDLs that we are aware of.

Effluent Outfall Preliminary Feasibility Review
Near-Shore Areas
PROJ NO: 20157
DATE: 10/21/2020
WRIGHT-PIERCE
Engineering a Better Environment
FIGURE: 1
JDM W:\GIS Development\Projects\MA\Barnstable\20157B CWMP\MXDs\Fig1-Basemapping-8x11.mxd

We recommend a minimum near field dilution factor of 50:1 in order to avoid the acute toxics criteria. Based on the above stated assumptions, we calculated the worst case simple near field dilution based on the minimum current velocity, design flow, and diffusers depth and length.

The dilution calculations for the Cape Cod Bay 001 and Nantucket Sound 002 were the same because we assumed the same depth (40 feet). The Nantucket Sound 001 location resulted in slightly lower dilution due to shallower depth (38 feet). The Canal location results were summarized in the May 2019 memorandum and not reiterated herein. The minimum current velocity condition results are summarized in Tables 3 and 4 and these results would be the most limiting for feasibility consideration.

TABLE 3 – DILUTION AT MINIMUM CURRENT VELOCITY

LOCATION CAPE COD BAY 001 AND NANTUCKET SOUND 002

Diffuser Depth	Diffuser Length	Mixing Area	Current Velocity	Current Flow	Design Effluent Flow	Design Effluent Flow	Simple Dilution
Feet	Feet	Sq-Ft	FPS	CFS	MGD	CFS	Ratio
40	220	8,800	0.033	290	3.54	5.48	54
40	200	8,000	0.033	264	3.54	5.48	49
40	100	4,000	0.033	132	3.54	5.48	25
40	50	2,000	0.033	66	3.54	5.48	13

TABLE 4 – DILUTION AT MINIMUM CURRENT VELOCITY

LOCATION NANTUCKET SOUND 001

Diffuser Depth	Diffuser Length	Mixing Area	Current Velocity	Current Flow	Design Effluent Flow	Design Effluent Flow	Simple Dilution
Feet	Feet	Sq-Ft	FPS	CFS	MGD	CFS	Ratio
38	220	8,360	0.033	276	3.54	5.48	51
38	200	7,600	0.033	251	3.54	5.48	47
38	100	3,800	0.033	125	3.54	5.48	24
38	50	1,900	0.033	63	3.54	5.48	12

Based on these simplified calculation results, we anticipate that it would be possible to design an ocean outfall at these locations and achieve worst case slack tide acute dilution factor of 50:1 or greater. The ZID values at higher ambient current velocities for the conceptual outfall configuration would range from 500:1 to 1,600:1.

The outfall would be designed to distribute effluent longitudinally to mix with the desired cross sectional receiving water area with the size and number of diffusers to result in a peak flow jet velocity 10 feet per second (fps) in order to optimize turbulence and initial mixing with the receiving water. A 24-inch to 30-inch outfall pipe would be utilized to convey effluent to the diffuser location.. Twenty 4-inch diffusers would be provided at 11-foot spacing along the final 220-foot section of the outfall, which would be installed at the target water depth.

As noted previously, we attempted to make conservative assumptions for this preliminary evaluation. Additional more detailed site-specific data and use of more sophisticated hydrodynamic computer models would be necessary to confirm outfall feasibility and refine the conceptual configuration. These models would also be necessary to analyze far-field mixing and dilution to assess the impact of effluent pollutant loading to ensure that water quality impairments would not occur. After an outfall location is selected, significant more detailed environmental review would also be required.

OTHER OUTFALLS

There are several existing outfalls with individual NPDES permits on Cape Cod or the immediate vicinity:

1) a large cooling water outfall to Cape Cod Bay from the Pilgrim Nuclear Power Plant;
2) a wastewater effluent outfall to Plymouth Harbor from the Plymouth WWTP;
3) a large cooling water outfall to the Cape Cod Canal from the Canal Station in Sandwich;
4) a small wastewater effluent outfall to the Cape Cod Canal from the Massachusetts Maritime Academy in Bourne; and
5) a wastewater effluent outfall to the Agawam River from the Wareham WPCF.

In addition, there are several additional outfalls we are aware of that are under consideration by municipalities for wastewater effluent on Cape Cod or the immediately vicinity:

1) a new regional outfall to the Cape Cod Canal from expanded JBCC wastewater treatment facilities potentially for Bourne, Falmouth, Mashpee, Sandwich, Barnstable and JBCC;
2) a new outfall to Buzzards Bay or Vineyard sound from the Falmouth wastewater treatment facilities for Falmouth; and
3) a significant expansion of the MMA outfall to the Cape Cod Canal from expanded Wareham wastewater treatment facilities potentially for Wareham, Marion, Plymouth, Bourne and MMA.

None of these outfalls are assured to move forward, but the Town should be mindful of how these efforts may impact the regulatory and public perception of effluent outfalls (positively or negatively).

PIPING ALIGNMENT ALTERNATIVES

A new effluent pump station would be sited at the WPCF to convey effluent to the outfall. For the purposes of this analysis, 24-inch force main and outfall piping has been assumed. Six potential alignment and outfall location alternatives were considered for this evaluation. Three general force main alignments were identified to reach the coastline: 1) the "eastern Cape Cod Bay route" terminates with three possible outfall locations to the east of Barnstable Harbor; 2) the "western Cape Cod Bay route" runs northwesterly to the Sandy Neck area at the Barnstable/Sandwich boundary to the west of Barnstable Harbor; and 3) the "southerly route to Nantucket Sound" includes two possible outfall locations, as noted previously. The route/outfall alternatives are generally described as follows:

Cape Cod Bay Outfall 001

- WPCF site – 340 LF
- Bearses Way (south) – 660 LF
- Route 28 (east) – 3,700 LF
- Airport roads (enter at Airport Rotary, exit at end of Runway 24) – 10,300 LF
- Railroad crossing (airport to Yarmouth Road) – 250 LF
- Yarmouth Road/Willow Street (north) – 10,800 LF
- Route 6A (east) – 180 LF
- Wharf Lane (north) – 2,400 LF
- Beach crossing/subaqueous outfall – 19,900 LF ***(Note: this is very close to the ACEC)***

Cape Cod Bay Outfall 002

- Same as CCB Outfall 001 Through Route 6A (east) – 26,230 LF
- Route 6A (east) – 5,920 LF
- Winter Street (north) – 2,140 LF
- Center Street (north) – 5,400 LF
- Beach crossing/subaqueous outfall – 14,800 LF

Cape Cod Bay Outfall 003

- Same as CCB Outfall 002 Through Route 6A (east) – 32,150 LF
- Route 6A (east) – 20,450 LF
- Corporation Road (north) – 4,500 LF
- Beach crossing/subaqueous outfall – 8,000 LF

Cape Cod Bay Outfall 004

- WPCF site – 3,100 LF
- Pitchers Way (north) – 1,100 LF
- Bearses Way (north) – 700 LF

- Route 132 (northwest) – 12,400 LF
- Route 6A (west) – 20,500 LF
- Sandy Neck Road (north) – 6,500 LF
- Beach crossing/subaqueous outfall – 5,000 LF ***(NOTE: this is through the ACEC)***

Nantucket Sound Outfall 001

- WPCF site – 2,260 LF
- Pitchers Way – 9,300 LF
- Marston Ave./Hyannis Ave. – 3,000 LF
- Beach crossing/subaqueous outfall – 12,200 LF

Nantucket Sound Outfall 002

- Same as NS Outfall 001 through Marston Ave./Hyannis Ave. – 14,560 LF
- Beach crossing/subaqueous outfall – 27,200 LF

CAPITAL COSTS

The necessary facilities would include an effluent pump station, 24-inch diameter force main piping from the pump station to the shore, 24-inch outfall piping and a diffuser assembly. For each of the force main and outfall route alternatives, quantities were estimated for 24-inch Force Main (WPCF site, local roads, state roads, airport roads, railroad crossings) and beach crossing/ subaqueous outfall piping. No costs are included for WPCF upgrades related to effluent quality. The following references were used as the basis for estimating unit costs for each item with cost information adjusted to current dollar values using the ENR Construction Cost Index:

- Wright-Pierce, "Shared Wastewater Management Study Towns of Bourne, Falmouth, Mashpee, Sandwich, and Joint Base Cape Cod", November 2017 Revised August 2019
- City of Rehoboth Beach, DE Ocean Outfall Bid Form and Total Bid Tabulation, August 2017. The Rehoboth Beach outfall project is similar to the conceptual outfall facilities for the Barnstable project. The outfall size is 24-inch with a diffuser assembly located approximately 6,000 feet offshore, in 40-feet deep water. We utilized the median bid item values (i.e., not the low bidder values). No adjustment was made based on project location.

Planning-level project costs have been prepared for the recommended facilities and are presented in Table 1. These planning-level costs were developed using standard cost estimating procedures consistent with industry standards utilizing concept layouts, unit cost information, and planning-level cost curves, as necessary. Total project capital costs include allowances for contingency, technical services, as well as fiscal, legal and administrative expenses. The project cost information presented herein is in current dollars and is based on ENR Index 11540 (October 2020). This is considered a "Class 4" estimate (AACE International), with an accuracy of -25% to +50%. While this is broad accuracy range, the relative cost differential among the options will remain consistent.

TABLE 1 – PIPE LENGTH (FEET) AND CAPITAL COSTS SUMMARY ($MILLION)

ENR CCI 11540 (OCTOBER 2020)

Item	Cape Cod Bay Outfall 001	Cape Cod Bay Outfall 002	Cape Cod Bay Outfall 003	Cape Cod Bay Outfall 004	Nantucket Sound Outfall 001	Nantucket Sound Outfall 002
Pipe Length (Feet)						
Force Main Length	28,630	39,690	57,100	44,300	14,560	14,560
Subaqueous Length	19,900	14,800	8,000	5,000	12,200	27,200
Total Length	48,530	54,490	65,100	49,300	26,750	41,760
Capital Costs ($M)						
Effluent Pump Station	5	5	5	5	5	5
Force Main	12	17	26	21	6	6
Subaqueous Pipe	132	93	42	19	74	188
General & Project Management	6	6	6	6	6	6
Construction Total	155	122	79	51	91	205
Project Development & Contingency	94	72	48	31	55	122
Total	**249**	**194**	**127**	**82**	**146**	**327**

Notes and Assumptions:

1) Project Development & Contingency includes technical services (including environmental studies, public consultation) estimated at 25% of construction cost, fiscal/legal/administrative estimated at 5% of the construction cost, and construction contingency estimated at 30% of the construction cost.
2) The force main unit costs include all appurtenant work including traffic control
3) Railroad crossing would be completed using horizontal directional drilling (HDD) or pipe jacking.
4) The beach crossing and initial subaqueous piping sections would be completed using HDD. For the purposes of this analysis, the maximum HDD length is assumed to be 3,800 feet, so the remainder of the subaqueous piping and diffuser assembly would be constructed using open cut trench similar to the Rehoboth Beach project.
5) Outfall general expenses, including mobilization, staging areas, and indeterminate quantity items would be similar for all the alternatives.

CONCLUSIONS

1) This preliminary feasibility review indicates that an ocean outfall is potentially feasible in either Cape Cod Bay or Nantucket Sound with respect to the principal physical parameters described herein. A previous preliminary feasibility review indicated a similar conclusion for the Cape Cod Canal location at a higher flow rate than identified herein. This review used annual average flow in the computations; this will need to be reviewed with the ultimately permitting agency (EPA).
2) Water depth is one of the key considerations for siting of an ocean outfall in order to achieve high initial dilution with the receiving water. The bathymetry of Cape Cod Bay is more conducive to an outfall location within a closer distance to shore than the bathymetry of Nantucket Sound. Locations with suitable water depth can be reached within 4,000 feet of the shore, whereas, similar water depths in Nantucket Sound are at least 12,000 feet off shore.
3) The Barnstable WPCF is closer to the Nantucket Sound shore than the Cape Cod Bay shore. The total land-based and water-based outfall piping length as well as the land-based and water-based environmental permitting will need to be considered.
4) The Town should consider moving forward in a step-wise manner, gaining incremental consensus along the way, and advancing/finalizing the regional planning decisions regarding other communities participation and future wastewater flows. Prior to conducting much more additional study it would be appropriate to consider a meeting with DEP, Massachusetts Coastal Zone Management, Massachusetts Natural Heritage and Endangered Species Program and Massachusetts Division of Marine Fisheries staff.
5) Significant additional study will be required in order to successfully site an ocean outfall including: regulatory outreach; field survey; habitat review; subaqueous siting; potential piping alignments; hydrodynamic, particulate and pollutant modeling; long-term water quality data collection; precipitation recharge and water balance analysis; cost evaluations; NPDES permit applications; and public consultation program.
6) It would be our expectation that the public consultation process will be extensive and intensive and will focus on questions routinely raised at wastewater-related public meetings (e.g., water balance, growth impacts, inadvertent discharge of partially treated wastewater to surface water, water quality impacts, habitat impacts, beach impacts, etc.). In the context of the potential JBCC regional discharge to the Cape Cod Canal, the Buzzards Bay Coalition has gone on record stating that they would not support a net increase in nitrogen loading to Buzzards Bay.
7) EPA, DEP and CZM will require site-specific data and detailed environmental monitoring/modeling of the fate of conservative and non-conservative contaminates as well as detailed hydraulic/hydrodynamic modeling (e.g., computational fluid dynamics, CORMIX, Visual Plumes/ UM3, etc.) in order to determine actual dilution factor at any of these locations.
8) Long-term water quality monitoring will be needed to establish existing conditions for MADEP to make an anti-degradation determination.
9) The application and review process for a new surface water discharges should be expected to take at least 5 to 7 years and the successful conclusion is not assured. Since the OSA

was amended in 2014 to allow consideration of new or expanded ocean outfalls, there have been no new outfalls implemented, and we are not aware of any completed application yet submitted to the MADEP for consideration. There is no precedent to provide a basis for expectations of the regulatory success of this process.

10) If the Town desires to keep a potential outfall among its potential options, it would be appropriate to incorporate alternatives analyses that will be required to meet the OSA regulations into the on-going CWMP process.
11) There is a wide range of costs for the evaluated alternatives with a range of $82M to $327M. The Cape Cod Bay Outfall 004 is the lowest cost alternative. The most significant cost factor is the length of the subaqueous piping. There are many site-specific characteristics that will influence the capital cost of the various elements of the project; however, the length of the subaqueous piping is the most significant cost factor because it has the highest unit cost and because there is paucity of recent relevant bid data. Relatively few effluent outfalls get constructed and the characteristics of each outfall are usually unique.
12) Depending on the regional scenarios being considered with other towns as a part of the CWMP, it is conceivable that an outfall could be shared among towns with shared implementation costs.

RE: Town of Barnstable Comprehensive Wastewater Management Plan
Expanded Environmental Notification Form

Dear Secretary Theoharides:

On behalf of the Town of Barnstable we are pleased to submit the attached Comprehensive Wastewater Management Plan (CWMP) and Expanded Environmental Notification Form (EENF) with a request for a Single Environmental Impact Report (SEIR) in accordance with MEPA regulations.

This CWMP is the culmination of years of wastewater planning efforts within the Town. The Town undertook this effort in order to address the multiple wastewater needs of the community. The recommended plan is a three-phase, 30-year plan, which includes substantial sewer expansion throughout the Town as well as non-traditional projects (which are anticipated to be submitted as a Notice of Project Change), in order to reduce nutrient loading to coastal waters and meet total maximum daily loads (TMDLs) for embayments. The plan also provides for fresh water pond and drinking water source protection, and supports sustainable growth.

Attached please find two copies of the CWMP and EENF. The appendices and an electronic copy of the CWMP have been provided on a flash drive, which can be found in the inside cover of the CWMP report. We look forward to continued coordination with MEPA on this important project. Please feel free to contact me with any questions regarding this document.

Sincerely,

Daniel W. Santos, P.E.

Commonwealth of Massachusetts

Does this project meet or exceed a mandatory EIR threshold (see 301 CMR 11.03)?
☒Yes ☐No

If this is an Expanded Environmental Notification Form (ENF) (see 301 CMR 11.05(7)) or a Notice of Project Change (NPC), are you requesting:

a Single EIR? (see 301 CMR 11.06(8))	☒Yes ☐No
a Special Review Procedure? (see 301CMR 11.09)	☐Yes ☒No
a Waiver of mandatory EIR? (see 301 CMR 11.11)	☐Yes ☒No
a Phase I Waiver? (see 301 CMR 11.11)	☐Yes ☒No

(Note: Greenhouse Gas Emissions analysis must be included in the Expanded ENF.)

Which MEPA review threshold(s) does the project meet or exceed (see 301 CMR 11.03)?
11.03(5)(a)(2) & 11.03(5)(a)(3)
Which State Agency Permits will the project require?
See Section 8.4 of Report
Identify any financial assistance or land transfer from an Agency of the Commonwealth, including the Agency name and the amount of funding or land area in acres:
Unknown at this time. Anticipate future applications for Clean Water SRF assistance.

Summary of Project Size & Environmental Impacts	Existing	Change	Total
LAND

GENERAL PROJECT INFORMATION – all proponents must fill out this section

PROJECT DESCRIPTION:

Describe the existing conditions and land uses on the project site: *The project site is the Town of Barnstable which is includes residential, commercial and limited industrial and agricultural land uses. The attached Comprehensive Wastewater Management Plan provides extensive detail on the Town's wastewater needs.*

Describe the proposed project and its programmatic and physical elements: *Project is a Town-wide Comprehensive Wastewater Management Plan. The details of the plan are explained in extensive detail in the attached Comprehensive Wastewater Management Plan, specifically in Section 5.*

Describe the on-site project alternatives (and alternative off-site locations, if applicable), considered by the proponent, including at least one feasible alternative that is allowed under current zoning, and the reasons(s) that they were not selected as the preferred alternative:
Section 8 of the attached Comprehensive Wastewater Management Plan describes the project alternative, which would be a "No Action" alternative. The Town considers the "No Action" alternative to be highly undesirable, irresponsible and inconsistent with the Local Comprehensive Plan of the Town and the Cape Cod community at large. In addition, the "No Action" alternative would result in regulatory issues for the Town as well as potential legal challenges.

Summarize the mitigation measures proposed to offset the impacts of the preferred alternative:
These mitigation measures are discussed in Section 8 of the attached Comprehensive Wastewater Management Plan.

If the project is proposed to be constructed in phases, please describe each phase:
The project is proposed to be constructed in phases. This is described in detail in Section 5 of the attached Comprehensive Wastewater Management Plan.

AREAS OF CRITICAL ENVIRONMENTAL CONCERN:

Is the project within or adjacent to an Area of Critical Environmental Concern?

☐ Yes (Specify_____)
☒ No

if yes, does the ACEC have an approved Resource Management Plan? ___ Yes ___ No;
If yes, describe how the project complies with this plan.

_____

Will there be stormwater runoff or discharge to the designated ACEC? ___ Yes ___ No;
If yes, describe and assess the potential impacts of such stormwater runoff/discharge to the designated ACEC.

_____

RARE SPECIES:

Does the project site include Estimated and/or Priority Habitat of State-Listed Rare Species? (see http://www.mass.gov/dfwele/dfw/nhesp/regulatory_review/priority_habitat/priority_habitat_home.htm)

☒ Yes (Specify_____) ☐ No

The project involves multiple projects that include the installation of sewer infrastructure, generally within right-of-ways, some of which are adjacent to mapped habitats.

HISTORICAL /ARCHAEOLOGICAL RESOURCES:

Does the project site include any structure, site or district listed in the State Register of Historic Place or the inventory of Historic and Archaeological Assets of the Commonwealth?

☒ Yes (Specify_____) ☐ No

The project is a Town-wide wastewater plan involving the installation of sewer infrastructure throughout the Town of Barnstable, which has numerous historic areas. When in historic districts, above ground components of the

projects (pump stations, etc.) may be subject to review, which is anticipated to be handled on a project by project basis. Candidate sites for these facilities will be reviewed against available mapping during preliminary design to determine if there are any anticipated historical / archaeological impacts.

If yes, does the project involve any demolition or destruction of any listed or inventoried historic or archaeological resources? ☐Yes (Specify_____) ☒No

The Town does not anticipate the project to involve any demolition or destruction of inventoried historic or archaeological resources.

WATER RESOURCES:

Is there an Outstanding Resource Water (ORW) on or within a half-mile radius of the project site? ___Yes _X__No;
if yes, identify the ORW and its location. _____

(NOTE: Outstanding Resource Waters include Class A public water supplies, their tributaries, and bordering wetlands; active and inactive reservoirs approved by MassDEP; certain waters within Areas of Critical Environmental Concern, and certified vernal pools. Outstanding resource waters are listed in the Surface Water Quality Standards, 314 CMR 4.00.)

Are there any impaired water bodies on or within a half-mile radius of the project site? _X__Yes ___No; if yes, identify the water body and pollutant(s) causing the impairment: *See attached list.*

Is the project within a medium or high stress basin, as established by the Massachusetts Water Resources Commission? ___Yes _X__No

STORMWATER MANAGEMENT:

Generally describe the project's stormwater impacts and measures that the project will take to comply with the standards found in MassDEP's Stormwater Management Regulations: *The project will have create minimal new impervious areas. Stormwater management BMPs will be incorporated as necessary for any new impervious surfaces.*

MASSACHUSETTS CONTINGENCY PLAN:

Has the project site been, or is it currently being, regulated under M.G.L.c.21E or the Massachusetts Contingency Plan? Yes ___ No _X__ ; if yes, please describe the current status of the site (including Release Tracking Number (RTN), cleanup phase, and Response Action Outcome classification):_____

The project involves multiple projects that include the installation of sewer infrastructure, generally within right-of-ways. Any properties that work is proposed on will be screened during the preliminary design process.

Is there an Activity and Use Limitation (AUL) on any portion of the project site? Yes ___ No ___;
if yes, describe which portion of the site and how the project will be consistent with the AUL:
_____.

Are you aware of any Reportable Conditions at the property that have not yet been assigned an RTN? Yes ___ No ___ ; if yes, please describe:_____

SOLID AND HAZARDOUS WASTE:

If the project will generate solid waste during demolition or construction, describe alternatives considered for re-use, recycling, and disposal of, e.g., asphalt, brick, concrete, gypsum, metal, wood: *Refer to Section 8.3.16 of the attached Comprehensive Wastewater Management Plan.*

Will your project disturb asbestos containing materials? Yes ___ No _X__ ;
if yes, please consult state asbestos requirements at http://mass.gov/MassDEP/air/asbhom01.htm

Describe anti-idling and other measures to limit emissions from construction equipment: *Refer to Section 8.3.16 of the attached Comprehensive Wastewater Management Plan.*

DESIGNATED WILD AND SCENIC RIVER:

Is this project site located wholly or partially within a defined river corridor of a federally designated Wild and Scenic River or a state designated Scenic River? Yes ___ No _X__ ;
if yes, specify name of river and designation:

If yes, does the project have the potential to impact any of the "outstandingly remarkable" resources of a federally Wild and Scenic River or the stated purpose of a state designated Scenic River?
Yes ___ No ___ ; if yes, specify name of river and designation: _____;
if yes, will the project will result in any impacts to any of the designated "outstandingly remarkable" resources of the Wild and Scenic River or the stated purposes of a Scenic River.
Yes ___ No ___ ;
if yes,describe the potential impacts to one or more of the "outstandingly remarkable" resources or stated purposes and mitigation measures proposed.

ATTACHMENTS:

1. List of all attachments to this document.
   Town of Barnstable Comprehensive Wastewater Management Plan (CWMP)
2. U.S.G.S. map (good quality color copy, 8-½ x 11 inches or larger, at a scale of 1:24,000) indicating the project location and boundaries.
   Locus Map provided in CWMP(Figure 1-1)
3.. Plan, at an appropriate scale, of existing conditions on the project site and its immediate environs, showing all known structures, roadways and parking lots, railroad rights-of-way, wetlands and water bodies, wooded areas, farmland, steep slopes, public open spaces, and major utilities.
   Numerous figures provided in CWMP
4 Plan, at an appropriate scale, depicting environmental constraints on or adjacent to the project site such as Priority and/or Estimated Habitat of state-listed rare species, Areas of Critical Environmental Concern, Chapter 91 jurisdictional areas, Article 97 lands, wetland resource area delineations, water supply protection areas, and historic resources and/or districts.
   Numerous figures provided in CWMP
5. Plan, at an appropriate scale, of proposed conditions upon completion of project (if construction of the project is proposed to be phased, there should be a site plan showing conditions upon the completion of each phase).
   Numerous figures provided in CWMP
6. List of all agencies and persons to whom the proponent circulated the ENF, in accordance with 301 CMR 11.16(2).
   List provided in CWMP.
7. List of municipal and federal permits and reviews required by the project, as applicable.
   List provided in Section 8.4 of CWMP.
8. *List of Impaired Waters in Town of Barnstable*

LAND SECTION – all proponents must fill out this section

I. Thresholds / Permits

A. Does the project meet or exceed any review thresholds related to **land** (see 301 CMR 11.03(1)
___ Yes _X__ No; if yes, specify each threshold:

II. Impacts and Permits

A. Describe, in acres, the current and proposed character of the project site, as follows:

	Existing	Change	Total
Footprint of buildings	_____	_____	_____
Internal roadways	_____	_____	_____
Parking and other paved areas	_____	_____	_____
Other altered areas	_____	_____	_____
Undeveloped areas	_____	_____	_____
Total: Project Site Acreage	_____	_____	_____

Project is a Town-wide wastewater plan which will generate minimal new impervious surfaces.

B. Has any part of the project site been in active agricultural use in the last five years?
___ Yes _X__ No; if yes, how many acres of land in agricultural use (with prime state or locally important agricultural soils) will be converted to nonagricultural use?

C. Is any part of the project site currently or proposed to be in active forestry use?
___ Yes _X__ No; if yes, please describe current and proposed forestry activities and indicate whether any part of the site is the subject of a forest management plan approved by the Department of Conservation and Recreation:

D. Does any part of the project involve conversion of land held for natural resources purposes in accordance with Article 97 of the Amendments to the Constitution of the Commonwealth to any purpose not in accordance with Article 97? ___ Yes _X__ No; if yes, describe:

E. Is any part of the project site currently subject to a conservation restriction, preservation restriction, agricultural preservation restriction or watershed preservation restriction? ___ Yes__X_ No; if yes, does the project involve the release or modification of such restriction? ___ Yes ___ No; if yes, describe:

F. Does the project require approval of a new urban redevelopment project or a fundamental change in an existing urban redevelopment project under M.G.L.c.121A? ___ Yes __X_ No; if yes, describe:

G. Does the project require approval of a new urban renewal plan or a major modification of an existing urban renewal plan under M.G.L.c.121B? Yes ___ No __X_; if yes, describe:

III. Consistency

A. Identify the current municipal comprehensive land use plan
Title: Town of Barnstable Comprehensive Plan 2010 Date: 2010

B. Describe the project's consistency with that plan with regard to:
1) economic development : Project will promote targeted economic development
2) adequacy of infrastructure: Project will improve sewer infrastructure
3) open space impacts: Project will have minimal impact on open space.
4) compatibility with adjacent land uses: Not applicable

C. Identify the current Regional Policy Plan of the applicable Regional Planning Agency (RPA)
RPA: Cape Cod Commission

Title: Cape Cod Regional Policy Plan Date: February 22, 2019

D. Describe the project's consistency with that plan with regard to:
1) economic development: Project will promote targeted economic development
2) adequacy of infrastructure: Project will improve sewer infrastructure
3) open space impacts: Project will have minimal impact on open space.

RARE SPECIES SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **rare species or habitat** (see 301 CMR 11.03(2))? ___ Yes __X_ No; if yes, specify, in quantitative terms:

(NOTE: If you are uncertain, it is recommended that you consult with the Natural Heritage and Endangered Species Program (NHESP) prior to submitting the ENF.)

B. Does the project require any state permits related to **rare species or habitat**? __ Yes _X__ No

C. Does the project site fall within mapped rare species habitat (Priority or Estimated Habitat?) in the current Massachusetts Natural Heritage Atlas (attach relevant page)? ___ Yes __X_ No.

D. If you answered "No" to all questions A, B and C, proceed to the **Wetlands, Waterways, and Tidelands Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Rare Species section below.

II. Impacts and Permits

A. Does the project site fall within Priority or Estimated Habitat in the current Massachusetts Natural Heritage Atlas (attach relevant page)? ___ Yes ___ No. If yes,
1. Have you consulted with the Division of Fisheries and Wildlife Natural Heritage and Endangered Species Program (NHESP)? ___Yes ___No; if yes, have you received a determination as to whether the project will result in the "take" of a rare species? ___ Yes ___ No; if yes, attach the letter of determination to this submission.

2. Will the project "take" an endangered, threatened, and/or species of special concern in accordance with M.G.L. c.131A (see also 321 CMR 10.04)? ___ Yes ___ No; if yes, provide a summary of proposed measures to minimize and mitigate rare species impacts

3. Which rare species are known to occur within the Priority or Estimated Habitat?

4. Has the site been surveyed for rare species in accordance with the Massachusetts Endangered Species Act? ___ Yes ___ No

4. If your project is within Estimated Habitat, have you filed a Notice of Intent or received an Order of Conditions for this project? ___ Yes ___ No; if yes, did you send a copy of the Notice of Intent to the Natural Heritage and Endangered Species Program, in accordance with the Wetlands Protection Act regulations? ___ Yes ___ No

B. Will the project "take" an endangered, threatened, and/or species of special concern in accordance with M.G.L. c.131A (see also 321 CMR 10.04)? ___ Yes ___ No; if yes, provide a summary of proposed measures to minimize and mitigate impacts to significant habitat:

WETLANDS, WATERWAYS, AND TIDELANDS SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **wetlands, waterways, and tidelands** (see 301 CMR 11.03(3))? ___ Yes _X__ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits (or a local Order of Conditions) related to **wetlands, waterways, or tidelands**? ___ Yes _X__ No; if yes, specify which permit:

C. If you answered "No" to both questions A and B, proceed to the **Water Supply Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Wetlands, Waterways, and Tidelands Section below.

II. Wetlands Impacts and Permits

A. Does the project require a new or amended Order of Conditions under the Wetlands Protection Act (M.G.L. c.131A)? ___ Yes ___ No; if yes, has a Notice of Intent been filed? ___ Yes ___ No; if yes, list the date and MassDEP file number: _____; if yes, has a local Order of Conditions been issued? ___ Yes ___ No; Was the Order of Conditions appealed? ___ Yes ___ No. Will the project require a Variance from the Wetlands regulations? ___ Yes ___ No.

B. Describe any proposed permanent or temporary impacts to wetland resource areas located on the project site:

C. Estimate the extent and type of impact that the project will have on wetland resources, and indicate whether the impacts are temporary or permanent:

Coastal Wetlands	Area (square feet) or Length (linear feet)	Temporary or Permanent Impact?
Land Under the Ocean		
Designated Port Areas		
Coastal Beaches		
Coastal Dunes		
Barrier Beaches		
Coastal Banks		
Rocky Intertidal Shores		
Salt Marshes		
Land Under Salt Ponds		
Land Containing Shellfish		
Fish Runs		
Land Subject to Coastal Storm Flowage		
Inland Wetlands		
Bank (If)		
Bordering Vegetated Wetlands		
Isolated Vegetated Wetlands		
Land under Water		
Isolated Land Subject to Flooding		
Borderi ng Land Subject to Flooding		
Riverfront Area		

D. Is any part of the project:

1. proposed as a **limited project**? ___ Yes ___ No; if yes, what is the area (in sf)?____
2. the construction or alteration of a **dam**? ___ Yes ___ No; if yes, describe:
3. fill or structure in a **velocity zone** or **regulatory floodway**? ___ Yes ___ No

4. dredging or disposal of dredged material? ___ Yes ___ No; if yes, describe the volume of dredged material and the proposed disposal site:
5. a discharge to an **Outstanding Resource Water (ORW)** or an **Area of Critical Environmental Concern (ACEC)**? ___ Yes ___ No
6. subject to a wetlands restriction order? ___ Yes ___ No; if yes, identify the area (in sf):
7. located in buffer zones? ___Yes ___No; if yes, how much (in sf) _____

E. Will the project:
1. be subject to a local wetlands ordinance or bylaw? ___ Yes ___ No
2. alter any federally-protected wetlands not regulated under state law? ___ Yes ___ No; if yes, what is the area (sf)?

III. Waterways and Tidelands Impacts and Permits

A. Does the project site contain waterways or tidelands (including filled former tidelands) that are subject to the Waterways Act, M.G.L.c.91? ___ Yes ___ No; if yes, is there a current Chapter 91 License or Permit affecting the project site? ___ Yes ___ No; if yes, list the date and license or permit number and provide a copy of the historic map used to determine extent of filled tidelands:

B. Does the project require a new or modified license or permit under M.G.L.c.91? ___ Yes ___ No; if yes, how many acres of the project site subject to M.G.L.c.91 will be for non-water-dependent use? Current ___ Change ___ Total ___
If yes, how many square feet of solid fill or pile-supported structures (in sf)?

C. For non-water-dependent use projects, indicate the following:
Area of filled tidelands on the site:_____
Area of filled tidelands covered by buildings:_____
For portions of site on filled tidelands, list ground floor uses and area of each use:
_____
Does the project include new non-water-dependent uses located over flowed tidelands? Yes ___ No ___
Height of building on filled tidelands_____

Also show the following on a site plan: Mean High Water, Mean Low Water, Water-dependent Use Zone, location of uses within buildings on tidelands, and interior and exterior areas and facilities dedicated for public use, and historic high and historic low water marks.

D. Is the project located on landlocked tidelands? ___ Yes ___ No; if yes, describe the project's impact on the public's right to access, use and enjoy jurisdictional tidelands and describe measures the project will implement to avoid, minimize or mitigate any adverse impact:

E. Is the project located in an area where low groundwater levels have been identified by a municipality or by a state or federal agency as a threat to building foundations? ___Yes ___ No; if yes, describe the project's impact on groundwater levels and describe measures the project will implement to avoid, minimize or mitigate any adverse impact:

F. Is the project non-water-dependent **and** located on landlocked tidelands **or** waterways or tidelands subject to the Waterways Act **and** subject to a mandatory EIR? ___ Yes ___ No;
(NOTE: If yes, then the project will be subject to Public Benefit Review and Determination.)

G. Does the project include dredging? ___ Yes ___ No; if yes, answer the following questions:
What type of dredging? Improvement ___ Maintenance ___ Both ____

What is the proposed dredge volume, in cubic yards (cys) _____
What is the proposed dredge footprint ____length (ft) ___width (ft)____depth (ft);
Will dredging impact the following resource areas?

Intertidal Yes__ No__; if yes, ___ sq ft
Outstanding Resource Waters Yes__ No__; if yes, ___ sq ft
Other resource area (i.e. shellfish beds, eel grass beds) Yes__ No__; if yes __ sq ft
If yes to any of the above, have you evaluated appropriate and practicable steps to: 1) avoidance; 2) if avoidance is not possible, minimization; 3) if either avoidance or minimize is not possible, mitigation?
If no to any of the above, what information or documentation was used to support this determination?

Provide a comprehensive analysis of practicable alternatives for improvement dredging in accordance with 314 CMR 9.07(1)(b). Physical and chemical data of the sediment shall be included in the comprehensive analysis.
Sediment Characterization

Existing gradation analysis results? __Yes ___No: if yes, provide results.
Existing chemical results for parameters listed in 314 CMR 9.07(2)(b)6? ___Yes ____No; if yes, provide results.

Do you have sufficient information to evaluate feasibility of the following management options for dredged sediment? If yes, check the appropriate option.

Beach Nourishment ___
Unconfined Ocean Disposal ___
Confined Disposal:
Confined Aquatic Disposal (CAD) ___
Confined Disposal Facility (CDF) ___
Landfill Reuse in accordance with COMM-97-001 ___
Shoreline Placement ___
Upland Material Reuse____
In-State landfill disposal____
Out-of-state landfill disposal ____
(NOTE: This information is required for a 401 Water Quality Certification.)

IV. Consistency:

A. Does the project have effects on the coastal resources or uses, and/or is the project located within the Coastal Zone? ___ Yes ___ No; if yes, describe these effects and the projects consistency with the policies of the Office of Coastal Zone Management:

B. Is the project located within an area subject to a Municipal Harbor Plan? ___ Yes ___ No; if yes, identify the Municipal Harbor Plan and describe the project's consistency with that plan:

WATER SUPPLY SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **water supply** (see 301 CMR 11.03(4))? ___ Yes __X_ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **water supply**? ___ Yes _X__ No; if yes, specify which permit:

C. If you answered "No" to both questions A and B, proceed to the **Wastewater Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Water Supply Section below.

II. Impacts and Permits

A. Describe, in gallons per day (gpd), the volume and source of water use for existing and proposed activities at the project site:

	Existing	Change	Total
Municipal or regional water supply	_____	_____	_____
Withdrawal from groundwater	_____	_____	_____
Withdrawal from surface water	_____	_____	_____
Interbasin transfer	_____	_____	_____

(NOTE: Interbasin Transfer approval will be required if the basin and community where the proposed water supply source is located is different from the basin and community where the wastewater from the source will be discharged.)

B. If the source is a municipal or regional supply, has the municipality or region indicated that there is adequate capacity in the system to accommodate the project? ___ Yes ___ No

C. If the project involves a new or expanded withdrawal from a groundwater or surface water source, has a pumping test been conducted? ___ Yes ___ No; if yes, attach a map of the drilling sites and a summary of the alternatives considered and the results. _____

D. What is the currently permitted withdrawal at the proposed water supply source (in gallons per day)? _____Will the project require an increase in that withdrawal? ___Yes ___No; if yes, then how much of an increase (gpd)? _____

E. Does the project site currently contain a water supply well, a drinking water treatment facility, water main, or other water supply facility, or will the project involve construction of a new facility? ___ Yes ___No. If yes, describe existing and proposed water supply facilities at the project site:

	Permitted Flow	Existing Avg Daily Flow	Project Flow	Total
Capacity of water supply well(s) (gpd)	_____	_____	_____	_____
Capacity of water treatment plant (gpd)	_____	_____	_____	_____

F. If the project involves a new interbasin transfer of water, which basins are involved, what is the direction of the transfer, and is the interbasin transfer existing or proposed?

G. Does the project involve:

1. new water service by the Massachusetts Water Resources Authority or other agency of the Commonwealth to a municipality or water district? ___ Yes ___ No
2. a Watershed Protection Act variance? ___ Yes ___ No; if yes, how many acres of alteration?
3. a non-bridged stream crossing 1,000 or less feet upstream of a public surface drinking

water supply for purpose of forest harvesting activities? ___ Yes ___ No

III. Consistency

Describe the project's consistency with water conservation plans or other plans to enhance water resources, quality, facilities and services:

WASTEWATER SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **wastewater** (see 301 CMR 11.03(5))? _X__ Yes ___ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **wastewater**? _X__ Yes ___ No; if yes, specify which permit: *See section 8.4 of CWMP*

C. If you answered "No" to both questions A and B, proceed to the **Transportation -- Traffic Generation Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Wastewater Section below.

II. Impacts and Permits

A. Describe the volume (in gallons per day) and type of disposal of wastewater generation for existing and proposed activities at the project site (calculate according to 310 CMR 15.00 for septic systems or 314 CMR 7.00 for sewer systems):

	Existing	Change	Total
Discharge of sanitary wastewater	1,670,000	1,914,500	3,584,500
Discharge of industrial wastewater			
TOTAL	1,670,000	1,914,500	3,584,500

	Existing	Change	Total
Discharge to groundwater			
Discharge to outstanding resource water			
Discharge to surface water			
Discharge to municipal or regional wastewater facility	1,670,000	1,914,500	3,584,500
TOTAL	1,670,000	1,914,500	3,584,500

ABOVE FLOWS ARE AVERAGE DAILY FLOWS

B. Is the existing collection system at or near its capacity? ___ Yes _X__ No; if yes, then describe the measures to be undertaken to accommodate the project's wastewater flows:

C. Is the existing wastewater disposal facility at or near its permitted capacity? _X__ Yes___ No; if yes, then describe the measures to be undertaken to accommodate the project's wastewater flows: *Discussed at length in CWMP.*

D. Does the project site currently contain a wastewater treatment facility, sewer main, or other wastewater disposal facility, or will the project involve construction of a new facility? _X__ Yes ___ No; if yes, describe as follows:

	Permitted	Existing Avg Daily Flow	Project Flow	Total
Wastewater treatment plant capacity (in gallons per day)	2,700,000	1,670,000	1,914,500	3,584,500

ABOVE FLOWS ARE AVERAGE DAILY FLOWS

E. If the project requires an interbasin transfer of wastewater, which basins are involved, what is the direction of the transfer, and is the interbasin transfer existing or new?

The project will involve interbasin transfer of wastewater and treated effluent. Wastewater will be collected from the Halls Creek, Centerville River, Three Bays, Popponesset Bay, and Barnstable Harbor Watersheds will be treated at the Barnstable Water Pollution Control Facility (BWPCF) in Lewis Bay Watershed. Treated effluent will be disposed of at the BWPCF and likely at a yet to be determined supplemental disposal location (watershed undetermined at this time).

F. Does the project involve new sewer service by the Massachusetts Water Resources Authority (MWRA) or other Agency of the Commonwealth to a municipality or sewer district? ___ Yes _X_ No

G. Is there an existing facility, or is a new facility proposed at the project site for the storage, treatment, processing, combustion or disposal of sewage sludge, sludge ash, grit, screenings, wastewater reuse (gray water) or other sewage residual materials? _X__ Yes ___ No; if yes, what is the capacity (tons per day):

	Existing	Change	Total
Storage			
Treatment			
Processing			
Combustion			
Disposal			

H. Describe the water conservation measures to be undertaken by the project, and other wastewater mitigation, such as infiltration and inflow removal.

III. Consistency

A. Describe measures that the proponent will take to comply with applicable state, regional, and local plans and policies related to wastewater management: *This project is the Town's Comprehensive Wastewater Management Plan and is intended to be an effort to comply with federal, state, and regional plans/policies related to wastewater management.*

B. If the project requires a sewer extension permit, is that extension included in a comprehensive wastewater management plan? ___ Yes ___ No; if yes, indicate the EEA number for the plan and whether the project site is within a sewer service area recommended or approved in that plan: *Project is a comprehensive wastewater management plan.*

TRANSPORTATION SECTION (TRAFFIC GENERATION)

I. Thresholds / Permit

A. Will the project meet or exceed any review thresholds related to **traffic generation** (see 301 CMR 11.03(6))? ___ Yes __X_ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **state-controlled roadways**? __X_ Yes ___ No; if yes, specify which permit: *Portions of the project will require access permits to install infrastructure within state highways.*

C. If you answered "No" to both questions A and B, proceed to the **Roadways and Other Transportation Facilities Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Traffic Generation Section below.

II. Traffic Impacts and Permits

A. Describe existing and proposed vehicular traffic generated by activities at the project site:

	Existing	Change	Total
Number of parking spaces	_____	_____	_____
Number of vehicle trips per day	_____	_____	_____
ITE Land Use Code(s):	_____	_____	_____

B. What is the estimated average daily traffic on roadways serving the site?

Roadway	Existing	Change	Total
1. _____	_____	_____	_____
2. _____	_____	_____	_____
3. _____	_____	_____	_____

C. If applicable, describe proposed mitigation measures on state-controlled roadways that the project proponent will implement:

D. How will the project implement and/or promote the use of transit, pedestrian and bicycle facilities and services to provide access to and from the project site?

C. Is there a Transportation Management Association (TMA) that provides transportation demand management (TDM) services in the area of the project site? ____ Yes ____ No; if yes, describe if and how will the project will participate in the TMA:

D. Will the project use (or occur in the immediate vicinity of) water, rail, or air transportation facilities? ____ Yes ____ No; if yes, generally describe:

E. If the project will penetrate approach airspace of a nearby airport, has the proponent filed a Massachusetts Aeronautics Commission Airspace Review Form (780 CMR 111.7) and a Notice of Proposed Construction or Alteration with the Federal Aviation Administration (FAA) (CFR Title 14 Part 77.13, forms 7460-1 and 7460-2)?

III. Consistency

Describe measures that the proponent will take to comply with municipal, regional, state, and federal plans and policies related to traffic, transit, pedestrian and bicycle transportation facilities and services:

TRANSPORTATION SECTION (ROADWAYS AND OTHER TRANSPORTATION FACILITIES)

I. Thresholds

A. Will the project meet or exceed any review thresholds related to **roadways or other transportation facilities** (see 301 CMR 11.03(6))? ___ Yes _X__ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **roadways or other transportation facilities**? __X_ Yes ___ No; if yes, specify which permit: *Portions of the project will require access permits to install infrastructure within state highways.*

C. If you answered "No" to both questions A and B, proceed to the **Energy Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Roadways Section below.

II. Transportation Facility Impacts

A. Describe existing and proposed transportation facilities in the immediate vicinity of the project site:

B. Will the project involve any

1. Alteration of bank or terrain (in linear feet)? _____
2. Cutting of living public shade trees (number)? _____
3. Elimination of stone wall (in linear feet)? _____

III. Consistency -- Describe the project's consistency with other federal, state, regional, and local plans and policies related to traffic, transit, pedestrian and bicycle transportation facilities and services, including consistency with the applicable regional transportation plan and the Transportation Improvements Plan (TIP), the State Bicycle Plan, and the State Pedestrian Plan:

ENERGY SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **energy** (see 301 CMR 11.03(7))? ___ Yes _X__ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **energy**? ___ Yes _X__ No; if yes, specify which permit:

C. If you answered "No" to both questions A and B, proceed to the **Air Quality Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Energy Section below.

II. Impacts and Permits

A. Describe existing and proposed energy generation and transmission facilities at the project site:

	Existing	Change	Total
Capacity of electric generating facility (megawatts)	_____	_____	_____
Length of fuel line (in miles)	_____	_____	_____
Length of transmission lines (in miles)	_____	_____	_____
Capacity of transmission lines (in kilovolts)	_____	_____	_____

B. If the project involves construction or expansion of an electric generating facility, what are:

1. the facility's current and proposed fuel source(s)?
2. the facility's current and proposed cooling source(s)?

C. If the project involves construction of an electrical transmission line, will it be located on a new, unused, or abandoned right of way? ___Yes ___No; if yes, please describe:

D. Describe the project's other impacts on energy facilities and services:

III. Consistency

Describe the project's consistency with state, municipal, regional, and federal plans and policies for enhancing energy facilities and services:

AIR QUALITY SECTION

I. Thresholds

A. Will the project meet or exceed any review thresholds related to **air quality** (see 301 CMR 11.03(8))? ___ Yes _X__ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **air quality**? ___ Yes _X__ No; if yes, specify which permit:

C. If you answered "No" to both questions A and B, proceed to the **Solid and Hazardous Waste Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Air Quality Section below.

II. Impacts and Permits

A. Does the project involve construction or modification of a major stationary source (see 310 CMR 7.00, Appendix A)? ___ Yes ___ No; if yes, describe existing and proposed emissions (in tons per day) of:

	Existing	Change	Total
Particulate matter			
Carbon monoxide			
Sulfur dioxide			
Volatile organic compounds			
Oxides of nitrogen			
Lead			
Any hazardous air pollutant			
Carbon dioxide			

B. Describe the project's other impacts on air resources and air quality, including noise impacts:

III. Consistency

A. Describe the project's consistency with the State Implementation Plan:

B. Describe measures that the proponent will take to comply with other federal, state, regional, and local plans and policies related to air resources and air quality:

SOLID AND HAZARDOUS WASTE SECTION

I. Thresholds / Permits

A. Will the project meet or exceed any review thresholds related to **solid or hazardous waste** (see 301 CMR 11.03(9))? ___ Yes _X__ No; if yes, specify, in quantitative terms:

B. Does the project require any state permits related to **solid and hazardous waste**? ___ Yes _X__ No; if yes, specify which permit:

C. If you answered "No" to both questions A and B, proceed to the **Historical and Archaeological Resources Section**. If you answered "Yes" to either question A or question B, fill out the remainder of the Solid and Hazardous Waste Section below.

II. Impacts and Permits

A. Is there any current or proposed facility at the project site for the storage, treatment, processing, combustion or disposal of solid waste? ___ Yes ___ No; if yes, what is the volume (in tons per day) of the capacity:

	Existing	Change	Total
Storage			
Treatment, processing			
Combustion			
Disposal			

B. Is there any current or proposed facility at the project site for the storage, recycling, treatment or disposal of hazardous waste? ___ Yes ___ No; if yes, what is the volume (in tons or gallons per day) of the capacity:

	Existing	Change	Total
Storage			
Recycling			
Treatment			
Disposal			

C. If the project will generate solid waste (for example, during demolition or construction), describe alternatives considered for re-use, recycling, and disposal:

D. If the project involves demolition, do any buildings to be demolished contain asbestos? ___ Yes ___ No

E. Describe the project's other solid and hazardous waste impacts (including indirect impacts):

III. Consistency

Describe measures that the proponent will take to comply with the State Solid Waste Master Plan:

HISTORICAL AND ARCHAEOLOGICAL RESOURCES SECTION

I. Thresholds / Impacts

A. Have you consulted with the Massachusetts Historical Commission? ___ Yes _X__ No; if yes, attach correspondence. For project sites involving lands under water, have you consulted with the Massachusetts Board of Underwater Archaeological Resources? ____Yes ____ No; if yes, attach correspondence

B. Is any part of the project site a historic structure, or a structure within a historic district, in either case listed in the State Register of Historic Places or the Inventory of Historic and Archaeological Assets of the Commonwealth? ___ Yes ___ No; if yes, does the project involve the demolition of all or any exterior part of such historic structure? ___ Yes ___ No; if yes, please describe:

C. Is any part of the project site an archaeological site listed in the State Register of Historic Places or the Inventory of Historic and Archaeological Assets of the Commonwealth? ___ Yes ___ No; if yes, does the project involve the destruction of all or any part of such archaeological site? ___ Yes ___ No; if yes, please describe:

D. If you answered "No" to all parts of both questions A, B and C, proceed to the **Attachments and Certifications** Sections. If you answered "Yes" to any part of either question A or question B, fill out the remainder of the Historical and Archaeological Resources Section below.

II. Impacts

Describe and assess the project's impacts, direct and indirect, on listed or inventoried historical and archaeological resources:
The project is a Town-wide wastewater plan involving the installation of sewer infrastructure throughout the Town of Barnstable, which has numerous historic areas. When in historic districts, above ground components of the projects (pump stations, etc.) may be subject to review, which is anticipated to be handled on a project by project basis. Candidate sites for these facilities will be reviewed against available mapping during preliminary design to determine if there are any anticipated historical / archaeological impacts.

III. Consistency

Describe measures that the proponent will take to comply with federal, state, regional, and local plans and policies related to preserving historical and archaeological resources: *Candidate sites for these facilities will be reviewed against available mapping during preliminary design to determine if there are any anticipated historical / archaeological impacts.*

PUBLIC NOTICE OF ENVIRONMENTAL REVIEW

PROJECT: Town of Barnstable Comprehensive Wastewater Management Plan

LOCATION: Town of Barnstable, Town-wide

PROPONENT: Town of Barnstable

The undersigned is submitting an Expanded Environmental Notification Form ("EENF") to the Secretary of Energy & Environmental Affairs on or before January 12, 2020

This will initiate review of the above project pursuant to the Massachusetts Environmental Policy Act ("MEPA", M.G.L. c. 30, s.s. 61-62I). Copies of the EENF may be obtained from:
Town of Barnstable Department of Public Works
Attn: Griffin Beaudoin, P.E., Town Engineer
382 Falmouth Road, Hyannis, MA 02601
(508)-790-6400

Copies of the EENF are also being sent to the Conservation Commission and Planning Board of The Town of Barnstable **where they may be inspected.**

The Secretary of Energy & Environmental Affairs will publish notice of the EENF in the Environmental Monitor, will receive public comments on the project for 30 days, and will then decide, within seven days, if an Environmental Impact Report is needed. A site visit and consultation session on the project may also be scheduled. All persons wishing to comment on the project, or to be notified of a site visit or consultation session, should write to the Secretary of Energy & Environmental Affairs, 100 Cambridge St., Suite 900, Boston, Massachusetts 02114, Attention: MEPA Office, referencing the above project.

CERTIFICATE OF THE SECRETARY OF ENERGY AND ENVIRONMENTAL AFFAIRS
ON THE
EXPANDED ENVIRONMENTAL NOTIFICATION FORM

PROJECT NAME	: Barnstable Comprehensive Wastewater Management Plan
PROJECT MUNICIPALITY	: Barnstable
PROJECT WATERSHED	: Cape Cod
EEA NUMBER	: 16148
PROJECT PROPONENT	: Town of Barnstable
DATE NOTICED IN MONITOR	: February 10, 2020

Pursuant to the Massachusetts Environmental Policy Act (MEPA; M.G. L. c. 30, ss. 61-62I) and Section 11.06 of the MEPA regulations (301 CMR 11.00), I have reviewed the Expanded Environmental Notification Form (EENF) and hereby determine that this project **requires** the submission of an Environmental Impact Report (EIR). The EENF was submitted to support the Proponent's request to file a Single EIR, rather than a Draft and Final EIR, pursuant to Section 11.06(8) of the MEPA regulations. The Proponent should submit a Single EIR in accordance with the Scope included in this Certificate.

Project Description

The EENF/Comprehensive Wastewater Management Plan (CWMP) described the Town of Barnstable's plan to address water quality management concerns resulting from population growth and increased development. The CWMP is a 30-year plan focused on traditional sewering solutions to replace the current dependence on septic systems; these solutions will be implemented in three 10-year phases. The plan has been designed to address multiple goals and needs of the community, specifically: nutrient removal, pond protection, drinking water protection, economic development and other related concerns regarding wastewater management.

Project Site

The Town of Barnstable is located in the central section of Cape Cod. Its year-round population is 45,193 (US Census 2010) while seasonal population can grow to more than three times that amount. The Town is organized into seven villages, and contains eight watersheds (no geographic relationship to the villages) including the Popponesset Bay Watershed, Rushy Marsh Watershed, Three Bays System Watershed, Centerville River System Watershed, Halls Creek Watershed, Lewis Bay Watershed, Barnstable Harbor Watershed and a very small portion of the Scorton Creek Watershed. Of these watersheds, three are contained solely within the Town's borders (Centerville River System Watershed, Halls Creek Watershed and Rushy Marsh Watershed), while the rest are shared with neighboring communities. Five of the eight watersheds have a Total Maximum Daily Load (TMDL) for nitrogen.

A TMDL is the maximum pollutant load a water body can receive and still meet water quality standards. TMDLs are created through a cooperative process involving multiple agencies. In the example of establishing TMDLs for nitrogen on Cape Cod, the process began with the Massachusetts Estuaries Project (MEP), a collaborative effort among MassDEP, University of Massachusetts School of Marine Science and Technology (SMAST), and the United States Geological Survey (USGS). The MEP developed nitrogen thresholds for 70 estuaries in Southeast Massachusetts using a water quality model that predicts water quality changes resulting from land use decisions. The model is run with different watershed loading values to demonstrate that the "nitrogen threshold" can be met, which is the upper limit of nitrogen loading that can enter the estuary and still meet water quality goals. Once MEP has established the nitrogen thresholds, MassDEP takes those numbers and prepares a draft TMDL for the water body. The draft TMDLs are then sent to the United States Environmental Protection Agency (USEPA) for approval; after such approval, the TMDLs become enforceable. As of the submittal date of the EENF/CWMP, TMDLs are in place for Popponesset Bay, Scorton Creek, the Three Bays System, the Centerville River System, Halls Creek, and Lewis Bay.

The Town's existing wastewater infrastructure includes the Barnstable Water Pollution Control Facility (BWPCF) located in Hyannis and a smaller wastewater plant in Marstons Mills referred to as the Marstons Mills Wastewater Treatment Plant (MMWWTP). The BWPCF treats an average daily flow of 1.67 million gallons per day (mgd) and has a maximum-month average daily flow of 1.97 mgd (2018 flow data). The BWPCF is permitted for a treatment capacity of 4.2 MGD and an effluent disposal capacity of 2.7 mgd.

The Federal Emergency Management Agency (FEMA) prepared a series of Flood Insurance Rate Maps (FIRM), effective July 16, 2014, that depict flood zones across the town. Coastal Flood Zones with Velocity Hazard (VE zone) are located along the Town's northern and southern coasts and the 100-year flood plain extends landward from the coasts with varying Base Flood Elevations (BFE).

Permitting and Jurisdiction

The project is undergoing MEPA review and is subject to preparation of a mandatory EIR pursuant to 301 CMR 11.03(5)(a)(3) of the MEPA regulations because it requires State Agency

Actions and involves the construction of one or more new sewer mains of ten or more miles in length. The project also exceeds the ENF threshold at 301 CMR 11.03(3)(b)(1)(f) because it involves the alteration of one half or more acres of any other wetlands. The project requires a Sewer Connection/Extension Permit and Groundwater Discharge Permit from Massachusetts Department of Environmental Protection (MassDEP) and a State Highway Access Permit from the Massachusetts Department of Transportation (MassDOT).

The project also requires review under the Massachusetts Endangered Species Act (MESA) by the Natural Heritage Endangered Species Program (NHESP) and review by the Massachusetts Historical Commission under Section 106 of the National Historic Preservation Act of 1966 and M.G.L. Chapter 9, sections 26-27C (950 CMR 70-71). The project may require Federal Consistency Review with the Massachusetts Coastal Zone Management Office. It is subject to review under the May 2010 MEPA Greenhouse Gas (GHG) Emissions Policy and Protocol ("the Policy").

The project will require an Order of Conditions (OC) from the Barnstable Conservation Commission (or in the case of an appeal, a Superseding Order of Conditions (SOC) from MassDEP). The project is subject to review by the Cape Cod Commission (CCC) to determine its consistency with the Section 208 Area-wide Water Quality Management Plan. The project will also require a National Pollutant Discharge Elimination System (NPDES) Construction Activities Permit from the U.S. Environmental Protection Agency (EPA) and authorizations from the U.S. Army Corps of Engineers (ACOE) under the General Permits for Massachusetts.

The Town will receive Financial Assistance from the Commonwealth through the State Revolving Fund (SRF). Therefore, MEPA jurisdiction is broad and extends to all aspects of the project with the potential to cause Damage to the Environment as defined in the MEPA regulations.

Environmental Impacts

As described in the EENF, implementation of the CWMP Recommended Plan will add one acre of impervious area and impact 390,000 sf (8.95 acres) of Land Subject to Coastal Storm Flowage (LSCSF) and 10,000 sf (0.22 acres) of Bordering Land Subject to Flooding (BLSF) for the proposed sewer infrastructure installation.

The project is intended to improve aquatic health and water quality by providing more effective wastewater treatment. Measures to avoid minimize, and mitigate project impacts include the use of erosion and sediment control measures during construction, and limiting areas of disturbance by locating work within previously disturbed areas where possible. Additional mitigation commitments should be identified in the Single EIR.

Single EIR Request

The Town requested that it be allowed to file a Single EIR in lieu of a Draft and Final EIR. The MEPA regulations indicate a Single EIR may be allowed, provided I find that the EENF:

a) describes and analyzes all aspects of the project and all feasible alternatives, regardless of any jurisdictional or other limitation that may apply to the Scope;

b) provides a detailed baseline in relation to which potential environmental impacts and mitigation measures can be assessed; and,

c) demonstrates that the planning and design of the Project use all feasible means to avoid potential environmental impacts.

The Proponent submitted an EENF to satisfy the requirements for a Single EIR and, as required, the EENF was subject to an extended comment period. In addition, a two-week extension of the 30-day comment period was granted at the request of the Town to prepare and distribute supplemental information.[1] The comment period closed on March 27, 2020. The EENF provided a detailed project description, a baseline for evaluating environmental impacts and a comprehensive alternatives analysis. The EENF identified how the project is designed to achieve consistency with regulatory standards, including water quality standards and measures to avoid, minimize and mitigate project impacts. Comments from MassDEP, NHESP and the Cape Cod Commission (CCC) identify issues that can be addressed in a Single EIR.

Special Review Procedure

While the Town's initial CWMP may be reviewed at a master planning level through a Single EIR, the plan sets forth a 30-year buildout scenario with varying levels of details for future phases. In particular, it is not yet clear, among other issues, whether specific phases will have unique or different impacts on natural resource areas from those currently known, whether the Town will choose to formally amend its CWMP to include non-traditional methods of water quality management for purposes of TMDL compliance, and whether regional solutions will become more viable and eventually obviate the need for a Town-specific CWMP. To outline the parameters for future reviews based on these and other similar circumstances, a Special Review Procedure (SRP) is warranted.

The Town has agreed to work with the MEPA Office to develop a SRP and submit a proposed framework prior to or together with the Single EIR. [2] The proposed SRP framework should address the methods for MEPA review in the circumstances outlined above, as well as other anticipated factors that may warrant special consideration. The SRP should also address the types of project changes that will require Notice of Project Change filings.

Review of the EENF

The CWMP included a comprehensive review of existing water quality in the Town's coastal waters, freshwater ponds, and groundwater sources of drinking water. The Town has continued to participate in the Massachusetts Estuaries Project (MEP) to conduct water quality

[1] Supplemental information entitled EENF Addendum dated March 12, 2020 from Griffin Beaudoin on behalf of the Town.
[2] Email stating that the Town is willing to work with the MEPA office to develop special review procedures for the Barnstable CMWP project prior to submission of the EIR dated March 24, 2020 from Griffin Beaudoin on behalf of the Town.

sampling and identify nutrient loading problems for the Town's coastal embayments. As stated above, the Technical Reports produced by the MEP are used by MassDEP and EPA to establish TMDLs for nitrogen loading to these coastal embayments and their tributaries.

CWMP

The CWMP documented that wastewater discharges from septic systems are the most significant source of nitrogen loading to coastal embayments. It outlined a long-term, three-phase approach to reducing nitrogen by managing wastewater through a variety of traditional means, such as sewering, expansion and improvements of the current wastewater treatment facility, and construction of new effluent disposal sites. It also outlined non-traditional methods including the control of fertilizer use and stormwater, public education, implementation of innovative and alternative (I/A) technologies, use of permeable reactive barriers (PRB), and wetland restoration.

The CWMP documented how the Town plans to address the water quality and wastewater needs of the community in each of three phases (Phase 1, Phase 2 and Phase 3) of the 30-year plan. The 30-year plan consists of primarily a conventional approach of sewer expansion, but the Town has designed the plan with the ability to integrate non-traditional projects in the last phase (Phase 3) based on demonstration projects. Based on data generated from future potential demonstration projects, the Town will assess how the CWMP can be modified to implement traditional strategies with the incorporation of nontraditional approaches. The focus area of the future non-traditional strategy will be located in the Three Bays Watershed.

A key component of the CWMP is an Adaptive Management Plan (AMP) that will include the reassessment and adjustment of the CWMP as phases of the plan are implemented. The AMP will be informed by the findings of a Wastewater Implementation Committee (WIC) that will monitor the progress of the CWMP, the results of on-going water quality monitoring in the watersheds, WWTF water quality reports, and population growth data. The AMP will assist the Town in evaluating its progress in attaining water quality goals, including compliance with the TMDLs, and adjusting the design or phasing of structural and non-structural components of the CWMP. It will also enable the Town to modify the Preferred Alternative's phasing, timing, or the specific areas to be sewered based on the results of the earlier implementation phases to comply with the anticipated nitrogen TMDLs.

The CWMP provided a summary of wastewater planning that has occurred to date, described existing conditions and land uses in the project area, identified future needs, and evaluated system alternatives to meet identified wastewater treatment demand and water quality objectives.

Needs Assessment

The CWMP included a needs assessment that identified Areas of Concern (AOC). The Town of Barnstable is currently exceeding the TMDL for nitrogen in its coastal embayments. The primary source of the problem is stormwater discharges, septic system failures, boat waste discharges, wildlife and other sources. Hydrographic modeling by MEP identified the needs assessment presented in the CWMP. The needs assessment was based on updated data related to

the original criteria and new information on I/A septic systems, rare species habitat, and areas with established TMDLs.

The Town completed a needs assessment in 2011 that was based on the presence of water supply protection zones, soil characteristics, density of lots, high groundwater, location within flood zones, septic system failures, shellfish closure areas, industrial land uses and filled wetlands. The assessment was completed to determine the nutrient loads generated by existing and future build-out of residential and commercial development in Barnstable. In developing the analysis, the Town reviewed the total number of parcels located within each of the watersheds for the marine embayments surrounding Barnstable and freshwater pond watersheds, and estimated the water use, wastewater flows and nutrient loading to be generated. Existing and future development parcels were evaluated to determine the need for sewers to address the water quality requirements and TMDLs of the Town's marine and freshwater water resources.

Development of an CWMP is an important step toward meeting TMDLs and restoring impaired waters. However, the plans to meet TMDL requirements for nutrient loading must always consider source reduction as the primary means of long-term nutrient control. Source reduction usually focuses on controlling watershed land use loads generated from human activity. Source reduction can include, but are not limited to, constructing new sewer systems, upgrading existing sewer systems (e.g. providing higher levels of treatment and eliminating combined sewer outflows), eliminating fertilizers, reducing runoff from impervious surfaces, reducing impervious surfaces, and tightening standards for new and upgraded septic systems.

In addition to source controls, successful nutrient management plans may include alternative nutrient control strategies to achieve the desired nitrogen concentrations specified in the TMDL and MEP reports. The EENF provided a detailed discussion of the source controls proposed.

Alternatives Analysis

The CWMP developed multiple water quality management scenarios to meet nitrogen removal goals identified in the needs assessment and the MEP studies. The scenarios reflect a broad array of options, including combinations of sewering, treatment facilities (including regional treatment facilities), effluent recharge sites, discharge of treated wastewater outside the watershed, and various levels of non-structural components such as I/A septic systems and permeable reactive barriers (PRB). The scenarios were intended to provide a screening-level analysis from which a subset would be selected, refined, and further analyzed. The Town determined that five of these scenarios warranted further analysis. Three additional scenarios were developed to evaluate regional wastewater alternatives.

The alternatives were evaluated and compared on the basis of cost, design requirements and reliability of technology, and construction impacts. The Town selected the Preferred Alternative (as presented previously in the Project Description section) because it will collect wastewater from a sufficient number of developed parcels throughout the Town and Popponesset Bay Watershed and the Cotuit Bay Subwatershed of the Three Bays Watershed to meet nitrogen removal requirements and provide sewer infrastructure to economic growth districts. It will meet

MEP and TMDL nitrogen reduction thresholds and can be phased in a manner that provides implementation flexibility.

Preferred Alternative

The Preferred Alternative has been designed to treat an average daily flow of 1.77 million gallons expected from the areas to be sewered, remove 176 kilograms per day (kg/day) of nitrogen after all three phases have been completed. Phase 1 in the first ten years is designed to treat an average daily flow of 782 thousand gallons per day and remove 78 kg/day of nitrogen, which is 44% of the total proposed of nitrogen removal for the project. Phase 2 in years ten to twenty years is designed to treat an average daily flow of 653 thousand gallons per day and remove 65 kg/day of nitrogen, which is 37% of the total proposed of nitrogen removal for the project. Phase 3 in years twenty to thirty years is designed to treat an average daily flow of 782 thousand gallons per day and remove 33 kg/day of nitrogen, which is 19% of the total proposed of nitrogen removal for the project. Please see Phasing Plan Statistics table below:

Phasing Plan Statistics Table

	Phase 1 (0-10 Years)	Phase 2 (10-20 Years)	Phase 3 (20-30 Years)	Total
WW Captured (gpd)	782,000	653,000	335,000	**1,770,000**
Load N Removed (kg/day)	78	65	33	**176**
Number of Parcels Affected	4,610	3,130	2,100	**9,870**
Approximate Road Miles	90	60	40	**190**
% of N Removed by Plan	44%	37%	19%	**100%**

****(wasterwater: WW; nitrogen: N)*

The Preferred Alternative identified in the CWMP will be implemented in following three phases:

PHASE 1 (0-10 Years)

- Construction of sewer infrastructure along Route 28 to address nutrient related issues within the Three Bays watershed. The Route 28 sewer infrastructure will be the major infrastructure to convey flow from westerly portions of the Town to the Barnstable Water Pollution Control Facility (BWPCF) located in Hyannis.
- Sewer expansion adjacent to Wequaquet Lake, Bearses Pond, Shallow Pond, Long Pond, Red Lily Pond, Lake Elizabeth, and Filenes Pond to address deteriorating water quality.
- Sewer expansion to accommodate identified economic development areas including along the Route 28, Old Yarmouth Road, Attuck's Lane/Route 132, Kidd's Hill, Independence Park, and Hyannis Harbor.
- Sewer expansion within the flood zones in the Craigville and Long Beach region to address septic system issues in the area.
- Sewer expansion adjacent to Prince Cove and Warren's Cove (most impaired waterbodies in the Three Bays Watershed) and the Marstons Mills River.
- Modifications at BWPCF including upgrades to aeration, denitrification upgrades, and upgrades to solids handling.
- Identification, permitting and construction of new effluent disposal site(s).

- Pursuit of a regional sewer option at Joint Base Cape Cod (JBCC).
- Implementation of non-traditional demonstration projects along the Marstons Mills River System (Mill Pond Dredging to cranberry bogs), together with monitoring and analysis of results.
- Continued embayment monitoring.

PHASE 2 (10-20 Years)

- Continued westerly sewer expansion along Route 28.
- Continued sewer expansion within the Centerville River Watershed, specifically the Centerville River East subwatershed and expansion adjacent to Bumps River.
- Sewer expansion into the Nye's Neck region to complete sewer expansion surrounding all of Wequaquet Lake.
- Sewer Expansion to areas south of Craigville Beach Road east of Covell's Beach.
- Sewer expansion into the Millway subwatershed (the one sub-watershed within the Barnstable Harbor Watershed requiring septic load removal per the MEP report).
- Sewer expansion within the Lewis Bay Watershed in the General Patton area and northern Hyannis Port.
- Continued sewer expansion within the Three Bays Watershed, directly adjacent to subembayments requiring septic load removal (Prince Cove and North Bay), to address areas with shortest groundwater travel times.
- Continued monitoring and analysis of non-traditional demonstration projects.
    1. During this phase, it is the Town's intention to present the monitoring and analysis of the non-traditional approaches to the regulatory agencies.
    2. If, as anticipated, the analysis of the monitoring program determines that the nontraditional approaches have improved conditions within the Three Bays Watershed, the Town would then enter discussions with regulatory agencies to pursue non-traditional "credits" in an effort to minimize the required sewer expansion proposed in Phase 3. The Town is not proposing any non-traditional "credits" at this time and has designed the sewer expansion plan to achieve the required septic load removals by traditional approaches only.
- Continued embayment monitoring.

PHASE 3 (20-30 Years)

- Continued sewer expansion into the northerly portion of the Three Bays Watershed.
- Continued sewer expansion within the Lewis Bay/Halls Creek Watershed.
- Continued monitoring and analysis of non-traditional projects and follow-up with regulatory agencies.
- Continued embayment monitoring.

In addition to the three phases of the 30-year plan, the CWMP also documented how the Town will conduct a parallel "3-stage" sewer expansion plan to address the wastewater needs in the Popponesset Bay Watershed and the Cotuit Bay Subwatershed of the Three Bays Watershed. The timing and execution of the 3-stage sewer expansion plan is subject to the involvement and collaboration of adjacent communities who also contribute nitrogen loads into these watersheds. The term "stages" was used for these sewer expansion areas because they do not have a

determined schedule as it is assumed that these areas would be served by a western treatment and disposal solution to accommodate the sewer expansion. The original plan developed by the Water Resources Advisory Committee (WRAC), recommended approaching these areas via an inter-municipal agreement (IMA). However, in order to address water quality concerns in Shoestring Bay and Cotuit Bay that would not be addressed via nitrogen sharing in an IMA, there is a desire for traditional wastewater solution in these areas. If a westerly solution becomes a reality, the Town intends to pursue sewer expansion the areas identified in the stages.

Conclusion

I recognize that the impacts caused by the discharge of nitrogen through both private septic and municipal sewer systems to surrounding water bodies can be severe and that this is a significant issue for towns on Cape Cod. The EENF describes a thorough evaluation of Barnstable's needs for wastewater and nutrient management. Specifically, much of the recommended plan is driven by the findings of the MEP which documented resource impairment from excess nitrogen loads. I support the comprehensive planning for wastewater management and applaud the effort that has gone into the development of this CWMP. In addition, the adaptive management approach proposed in this plan provides a flexible management framework that allows for changes to the planned implementation schedule, based upon future unknown variables, such as changes in water quality, future build-out rates in different watersheds, and economics.

Comments from State agencies and environmental groups are generally supportive of the Town's effort in preparing the CWMP. Based on review of the EENF, consultation with State Agencies and review of comment letters, I have determined that the Proponent may submit a Single EIR. This decision to allow a Single EIR is conditioned upon the Town's agreement to establish a SRP to allow for additional public review and input on future phases of the CWMP as information and plans are developed. The Single EIR should be prepared in accordance with the following Scope.

SCOPE

General

The Single EIR should follow Section 11.07 of the MEPA regulations for outline and content, as modified by this Scope. The Single EIR should identify and describe any changes to the project since the filing of the EENF and provide an update on State, local and federal permitting.

Project Description

The Single EIR should include an executive summary, it should identify significant environmental benefits and impacts, and measures that will be taken to avoid, minimize and mitigate adverse impacts. The Single EIR should describe the planning process that has occurred to date, and the proposed schedule for the remaining phases of planning, design, environmental permitting and review, and construction. Information should be provided for each area where

construction is proposed, including maps that show where sewer lines, cross-country easements, pumping stations, and other facilities will be located, to the extent it is available when the Single EIR is submitted.

The Single EIR should discuss the state permitting process for this project and describe how it will meet all applicable performance standards. I encourage early coordination with MassDEP during preparation of the Single EIR as requested in the agency's comments.

CWMP

The Single EIR should include the following supplemental information as related to the CWMP:

Alternatives Analysis

The Preferred Alternative presented in the EENF does not rely on any percent nitrogen removal credit for the non-traditional components of the CWMP, including dredging, aquaculture, land use controls and open space acquisition, and stormwater management and fertilizer use reduction programs and provided little detail on these non-traditional components of the CWMP. Regardless of the fact that the Town is not seeking any percent nitrogen removal credit, the Single EIR should provide a conceptual description of non-traditional nitrogen reduction measures that it intends to implement through demonstration projects assist to achieve the nitrogen removal, including, in addition to water quality benefits, a conceptual description of environmental impacts and mitigation measures to the extent this can be identified at this stage. The proposed SRP framework should include procedures to review non-traditional methods of nitrogen removal, either together with the CWMP or outside any review procedures applicable to the CWMP and/or any subsequent amendments.

In addition, the Single EIR should provide more detail about the water quality embayment monitoring program described under the Preferred Alternative, including the general approach to be used, how it will be implemented, monitoring locations, and water quality parameters to be measured. It should address how the monitoring program will be designed to evaluate the effectiveness of non-traditional treatment options.

Regional Planning

The Town is investigating several opportunities for regional cooperation with neighboring towns. Many local studies have shown that economies of scale from a cost savings and sustainability perspective offer significant advantages to regional solutions. Barnstable shares several watersheds with neighboring communities and is investigating community partnerships with them. The Town shares the Popponesset Bay Watershed with Sandwich and Mashpee. The Towns have executed an inter-municipal agreement (IMA) to establish a work group. The objective of the work group is to come to agreement on a formula for allocation of responsibilities and costs, establish a municipal fiscal agent lead. The EENF also discusses that there are water quality concerns in the Shoestring Bay Subwatershed of Popponesset Bay and the Cotuit Bay Subwatershed of the Three Bays Watershed that would not be addressed via nitrogen

trading in the IMA. As aforementioned, a potential "westerly solution" would allow Barnstable to carry out the 3-stage sewer expansion plan addressing those concerns.

The Town of Barnstable has also been participating in discussions with the Upper Cape Communities in an effort to form an Upper Cape regional treatment and disposal solution at Joint Base Cape Cod (JBCC). The EENF states that Barnstable, Bourne, Falmouth, Mashpee and Sandwich are conducting a regional evaluation of wastewater discharge options on Joint Base Cape Cod JBCC. Specifically, the EENF also states that the Towns are discussing the possibility of utilizing the existing wastewater treatment facility at JBCC, which currently consists of a treatment plant and four infiltration basins northwest near the Cape Cod Canal, as a regional facility. Comments from MassDEP express support for the regional efforts of the Upper Cape Communities and Barnstable and will continue provide regulatory guidance.

The Single EIR should provide updates on opportunities for wastewater planning on a regional scale identified in the EENF, including its coordination with Bourne, Falmouth, Mashpee and Sandwich to establish nutrient loadings and discussions related to the potential use of the JBCC wastewater facility. In addition, the NHESP notes that the four existing infiltration basins at JBCC near the Cape Cod Canal are located within the Camp Edwards Wildlife Management Area. Chapter 47 of the Acts of 2002 transferred the care, custody and control of the northern 15,000 acres of JBCC to the Division as the Camp Edwards Wildlife Management Area to conserve fish and wildlife resources for the benefit of the citizens of the Commonwealth. I remind the Town that any projects or activities within the Camp Edwards Wildlife Management Area, including but not limited to any potential upgrades to or expansion of existing wastewater treatment facilities, would require review and approval by the NHESP. To the extent these planning efforts result in regional wastewater management solutions that obviate the need for town-specific CWMPs, the SRP framework should propose a mechanism for conducting appropriate MEPA reviews.

Adaptive Management Plan

The EENF discusses how an Adaptive Management Plan (AMP) will allow for a systematic and prescribed process to report on the Town's activities and to incorporate new technical information and potential agreements among the towns in the shared watersheds. The AMP will assist the Town to evaluate the Town's compliance with established TDMLs and identify the need for adjustments or mid-course corrections to subsequent phases of the structural and non-structural components of the Preferred Alternative program.

Comments from MassDEP recognize that this the AMP is subject to modification based on partnerships with towns that share common watersheds and the advancement of nutrient management strategies and technologies. The Single EIR should provide a detailed description of the Town's proposed AMP and its water quality monitoring program in the Town of Barnstable.

<u>Land Use and Alteration</u>

The Single EIR should provide an estimate of the total amount of alteration associated with the proposed project in greater detail than what was provided in the EENF (including areas

to be altered for sewer mains, pump station impacts, and other project components). The Single EIR should include a breakdown showing the amount of alteration for different project elements. The Single EIR should clarify the location, type and amount of alteration in previously undisturbed areas.

The Single EIR should clarify the amount of new impervious area associated with the construction of the components of the Town's CWMP. The Single EIR should describe how the Town's proposed stormwater management system will be designed and constructed to be consistent with MassDEP's stormwater management regulations and policy standards and avoid and minimize adverse impacts associated with any new impervious area. The Single EIR should describe proposed measures to manage stormwater during project construction.

Growth Management

Executive Order #385 requires that State and local agencies engage in protective and coordinated planning oriented towards resource protection and sustainable economic development. For reasons of both environmental protection and fiscal prudence, investments in public infrastructure should be carefully targeted toward those areas for which clear existing needs have been established and for areas where denser development is appropriate, thereby relieving development pressures on open space, agricultural lands, and other valuable natural resources.

The Single EIR should identify parcels located within the proposed sewer service areas that are undeveloped or that have development constraints due to the lack of sewers, and compare the potential secondary growth impacts that may be induced by public sewers with local and regional growth management policies and zoning. It should examine what regulatory or physical constraints would remain on home expansions after sewers are constructed, and whether such expansions might have unanticipated impacts on estimated wastewater flows and water use.

Wetlands and Waterways

According to the EENF, the project will impact LSCSF and BLSF. Although not indicated in the EENF, the project may qualify as a limited project pursuant to 310 CMR 10.53(3)(d) for the construction of underground public utilities (sewer lines). In addition, construction of wastewater treatment plants' related structures are exempt from the requirements for Riverfront Area pursuant to 310 CMR 10.58(6)(h). According to the EENF, the majority of work within these areas will occur within paved right-of-way, will be temporary in nature, and will be restored to original conditions following completion of construction. The Single EIR should identify areas of impacts to wetland resource areas and describe mitigation measures. It should address the project's compliance with appropriate standards of the Wetlands Regulations (310 CMR 10.00).

The Single EIR should also delineate on a plan of reasonable scale all environmental resources areas located within areas proposed for sewering, including wetlands, drinking water supplies, sensitive habitats, fisheries, designated Areas of Critical Environmental Concern (ACEC), Article 97 lands, historic resources, and agricultural lands. Where it has been

demonstrated that impacts are unavoidable, the Single EIR should demonstrate that the impacts have been minimized, and that adequate mitigation will be pursued.

I note that any proposed sewer lines that cross over or under tidelands or tidal rivers and streams will likely require a Chapter 91 License from MassDEP. The Single EIR should include information on which future phases of the CWMP are located in Chapter 91 jurisdictional areas or landlocked tidelands subject to a Public Benefits Determination by the Secretary of EEA.

Rare Species

The Town of Barnstable's ponds, bays and estuarine waters provide critical foraging, breeding, migration and over-wintering habitats for a suite of state-listed rare species. Portions of Barnstable are mapped as Priority Habitat for state-listed rare species. All projects proposed within Priority Habitat, which are not otherwise exempt from review pursuant to 321 CMR 10.14, require review through a direct filing with the Natural Heritage and Endangered Species Program (NHESP) within the Division of Fisheries and Wildlife pursuant to the Massachusetts Endangered Species Act (M.G.L. c. 131A) and its implementing regulations (MESA; 321 CMR 10.00).

As described in the EENF, a portion of the phased sewer main installations is located near or within Priority Habitat for state-listed rare species. According to comments from NHESP, based on its review of the EENF it appears that the proposed work is exempt from MESA review (321 CMR 10.14). However, if proposed activities do not meet the MESA exemptions, a checklist for these activities must be filed with NHESP. The Town should submit detailed construction plans to NHESP to confirm the exempt status.

If NHESP should subsequently find that the project will require a Conservation and Management Permit pursuant to MESA, the Single EIR should analyze the impacts to rare or endangered species and evaluate avoidance/mitigation strategies. I ask that the Town continue to work closely with NHESP and consult with the Barnstable Conservation Commission during the preparation of this section of the Single EIR. The Single EIR should identify necessary project construction and post-construction conditions and commitments to avoid an adverse impact to resource area habitats of state-listed species located within and adjacent to the project areas. The Single EIR should report on the results of the Town's consultations with NHESP. If sufficient detail is not available to conduct a full evaluation of all phases, the Town should propose procedures in the SRP to enable a review of rare species impacts as appropriate during future phases of the CWMP buildout plan.

NHESP's comments indicate that, in addition to the proposed sewering, any proposed upgrades to or expansions of the wastewater treatment facilities would require review by the NHESP for compliance with the MESA that because they are located within Priority Habitat. The Single EIR should address applicability of any permitting requirements by NHESP in the manner described above.

Wastewater / Facility Upgrades

The EENF describes that the Barnstable Water Pollution Control Facility (BWPCF) discharges all of its treated wastewater effluent to disposal sites at the treatment facility. The Town is planning to invest in maintenance and improvement of existing infrastructure, including pump stations, collection system upgrades, and infrastructure to minimize infiltration and inflow (I/I). The Town is planning to upgrade and expand the facility's treatment capacity throughout Phase 1 of the CWMP with improvements to the reactor trains, modifications of the secondary clarifier and expansion of the aeration system. The goal is to reduce the annual effluent nitrogen concentration while accommodating the anticipated new flow from sewer expansion projects.

In 2017, MassDEP conservatively lowered the disposal capacity in the Town's groundwater discharge permit to allow time to study the disposal capacity and understand the potential downgradient hydrogeological impacts that may result from increased sewer flows. Where soil and groundwater conditions are favorable for recharge of groundwater, treated sewage effluent can infiltrate into the soil and move down to the groundwater creating a recharge cappacity. The lower level of soils then act as a natural filter and can remove essentially all suspended solids, biodegradable materials, bacteria, viruses, and other microorganisms. Significant reductions in nitrogen, phosphorus, and heavy metals concentrations can also be achieved. The preliminary findings presented in the EENF indicate that the estimated average annual recharge capacity of the BWPCF is 2 mgd when the depth to groundwater is less than 8 feet at a downgradient receptor. The CWMP states that the annual average flow is not expected to reach 2 mgd until 2027. MassDEP supports the Town's current plan to maintain flows below 2 mgd until the Town designs, permits and constructs the new disposal effluent sites.

MassDEP supports the Town's current plan to maintain flows below 2 mgd until the Town designs, permits and constructs the new disposal sites. The Single EIR should present the proposed locations and preliminary designs for the proposed new disposal sites. As requested by MassDEP. MassDEP also requests that the Town investigate and permit additional wastewater sites in parallel with the wastewater treatment upgrades planned Phase 1. The Town should continue consulting with MassDEP and present the results of the discussion in the Single EIR.

In addition, the Single EIR should include any identified upgrades and or modifications of the wastewater treatment facilities through Phase 1, and, to the extent future upgrades are anticipated, either provide details on those upgrades or a process by which they could be reviewed through the SRP if relevant thresholds are met or exceeded.

Climate Change

Governor Baker's Executive Order 569: Establishing an Integrated Climate Change Strategy for the Commonwealth (EO 569; the Order) was issued on September 16, 2016. The Order recognizes the serious threat presented by climate change and directs agencies within the administration to develop and implement an integrated strategy that leverages state resources to combat climate change and prepare for its impacts. The Order seeks to ensure that Massachusetts will meet greenhouse gas (GHG) emissions reduction limits established under the Global Warming Solution Act of 2008 (GWSA) and will work to prepare state government and cities

and towns for the impacts of climate change. Review of these issues through the GHG Policy and requirements to analyze the effects of climate change through EIR review is an important part of this statewide strategy. These analyses inform State Agencies and proponents' understanding of a project's GHG emissions and a project's vulnerability to the effects of climate change.

Adaptation and Resiliency

The Town is a participant in the Commonwealth's Municipal Vulnerability Preparedness (MVP) program. The MVP program is a community-driven process to define natural and climate-related hazards, identify existing and future vulnerabilities and strengths of infrastructure, environmental resources and vulnerable populations, and develop, prioritize and implement specific actions the Town can take to reduce risk and build resilience.

Components of the wastewater collection infrastructure, such as proposed pump station sites, appear to be located within coastal flood zones. The Town should consider alternative locations for the infrastructure proposed to be sited in these locations, or to otherwise implement climate change adaptation measures to protect the pump stations. The Single EIR should review alternative locations for system components, such as pump stations, including locations outside the floodplain. It should identify design features that could increase the resiliency of the proposed infrastructure under future sea level conditions. The Town should consult the best available data on climate change predictions, including data available on the resilientMA.org website, to develop climate change scenarios for the project and identify potential adaptation measures for the appropriate design life of the project. EEA's Climate Change Adaptation Report (September 2011) and the Town's Climate Change Vulnerability Assessment (dated December, 2019) provide additional resources to assist in this analysis. The Single EIR should discuss climate resiliency considerations made in designing and implementing other components of the CWMP, including the siting and construction of new sewer mains.

Greenhouse Gas Emissions

This project is subject to review under the May 5, 2010 MEPA GHG Policy. The Policy requires Proponents to quantify carbon dioxide (CO_2) emissions and identify measures to avoid, minimize or mitigate such emissions. The analysis should quantify the direct and indirect CO_2 emissions of the project's energy use. Direct emissions include on-site stationary sources, which typically emit GHGs by burning fossil fuel for heat, hot water, steam and other processes. Indirect emissions result from the consumption of energy, such as electricity, that is generated off-site by burning of fossil fuels, and from emissions from vehicles used by employees, vendors, customers and others. The Policy directs proponents to use applicable building codes to establish a project emissions baseline that is "code-compliant." However, there is no building energy code equivalent that applies specifically to WWTFs or energy use models (such as eQUEST) designed to estimate the projected energy use of the WWTF processing energy loads.

The Single EIR should include a more project-specific GHG evaluation of emissions associated with modification to the WWTF and any other facilities, such as pump stations, that may emit GHG. It should establish a Base Case and an as-proposed Preferred Alternative Case along with providing the other information required by the Policy. Both the projected energy

consumption and related GHG emission should be quantified for both cases. Design assumptions for the base case should be based on a typical WWTF and pump station design that meets the requirements of TR-16, *Guides for the Design of Wastewater Treatment Works*, 2016 Edition, which is commonly used as a guide for wastewater facility design in Massachusetts. The as-proposed Preferred Alternative design should include features and measures that would result in a significant reduction from the Base Case in both the consumption of grid electricity and the related GHG emissions. Measures that should be evaluated include: increasing piping sizes to reduce friction loss; use of premium efficiency pumps and motors; and use of variable frequency pump drives (VFD).

The Town should consult MassDEP's "Energy Efficiency and Renewable Energy Opportunities at Water and Wastewater Facilities" webpage[3], the Water Environment Research Foundation's *Utilities of the Future Energy Findings*[4] report published in 2014, the EPA's *Evaluation of Energy Conservation Measures for Wastewater Facilities*[5] (2010), the *Water and Wastewater Energy Management Best Practices Handbook*[6] (2010) prepared by the New York State Energy Research and Development Authority, and other resources to identify energy efficiency practices at WWTFs. The Single EIR should review energy-efficient alternatives identified in the reports cited above and indicate whether the Town will adopt the measure or not, and provide a rationale for the decision. The Single EIR should review opportunities for on-site energy generation, including biogas and solar photovoltaic (PV) systems. The Town should consult with MEPA staff before completing this analysis.

Historical/Archaeological Resources

The Town should provide MHC with a US Geological Survey topographical map that clearly locates the phased project areas and scaled project plans showing existing and proposed conditions. These plans should be submitted to MHC as early as possible during the design phase corresponding to each of the proposed project development phases. The Town should continue to coordinate with MHC to ensure review of any potential historic impacts from the project and the Single EIR should provide an update on the status of these discussions. If MHC deems the project to have an "adverse effect" on historic or archaeological resources, the Single EIR should include a discussion of mitigation measures that the Town will undertake to address the adverse effect.

Construction Impacts

The EENF indicated that the project will require a Access Permit from MassDOT to address work within State-controlled roadways. The Town should consult with MassDOT to confirm what elements of the project will require approval. The Single EIR should identify areas

[3] http://www.mass.gov/eea/agencies/massdep/climate-energy/energy/water-utilities/energy-efficiency-at-water-and-wastewater-facilities.html
[4] Available online at https://www.werf.org/a/ka/Search/ResearchProfile.aspx?ReportId=ENER6C13
[5] Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi/P1008SBM.PDF?Dockey=P1008SBM.PDF
[6] Available online at https://www.nyserda.ny.gov/-/media/Files/Programs/Clean-Energy-Communities/NYSERDA-Water-Wastewater-Energy-Management-Best-Practices-Handbook.pdf

subject to MassDOT review, describe potential project impacts in those areas, and identify mitigation measures.

Construction period impacts and mitigation measures should be described in the Single EIR, including impacts from noise and dust, impacts on trees and other vegetation, and traffic impacts. Measures that will be taken to minimize and mitigate construction period impacts (in particular impacts on sensitive receptors or exceptional resources) should be detailed.

While much of the project will occur within existing roadways, it will increase impervious area by approximately one acre due to the placement of pump stations and other system components. The Single EIR should describe impervious areas to be created by the project and review alternatives for minimizing new impervious surfaces. The Single EIR should identify sedimentation and erosion control measures to be used during construction. A Stormwater Pollution Prevention Plan will be developed for the project in accordance with MassDEP's Stormwater Management Standards. The Single EIR should describe any stormwater best management practices (BMPs) to be constructed to offset new impervious area.

All construction and demolition activities should be managed in accordance with applicable MassDEP's regulations regarding Air Pollution Control (310 CMR 7.01, 7.09-7.10), and Solid Waste Facilities (310 CMR 16.00 and 310 CMR 19.00, including the waste ban provision at 310 CMR 19.017). The project should include measures to reduce construction period impacts (e.g., noise, dust, odor, solid waste management) and emissions of air pollutants from equipment, including anti-idling measures in accordance with the Air Quality regulations (310 CMR 7.11). I encourage the Town to require that its contractors use construction equipment with engines manufactured to Tier 4 federal emission standards, or select project contractors that have installed retrofit emissions control devices or vehicles that use alternative fuels to reduce emissions of volatile organic compounds (VOCs), carbon monoxide (CO) and particulate matter (PM) from diesel-powered equipment. Off-road vehicles are required to use ultra-low sulfur diesel fuel (ULSD). If oil and/or hazardous materials are found during construction, the Proponent should notify MassDEP in accordance with the Massachusetts Contingency Plan (310 CMR 40.00). All construction activities should be undertaken in compliance with the conditions of all State and local permits. I encourage the Townto reuse or recycle construction and demolition (C&D) debris to the maximum extent.

Mitigation Measures/Section 61 Findings

The Single EIR should include a separate chapter summarizing proposed mitigation measures. This chapter should also include draft Section 61 Findings for each permit or other approval to be issued by State Agencies. The Single EIR should contain clear commitments to implement these mitigation measures, estimate the individual costs of each proposed measure, identify the parties responsible for implementation, and a schedule for implementation. The Single EIR should clearly indicate which mitigation measures will be constructed or implemented based upon project phasing to ensure that adequate measures are in place to mitigate impacts associated with each phase.

Response to Comments

The Single EIR should contain a copy of this Certificate and a copy of each comment letter received. In order to ensure that the issues raised by commenters are addressed, the Single EIR should include direct responses to comments to the extent that they are within MEPA jurisdiction. This directive is not intended to, and shall not be construed to, enlarge the Scope of the Single EIR beyond what has been expressly identified in this certificate.

Circulation

The Proponent should circulate the Single EIR to those parties who commented on the EENF, to any State Agencies from which the Proponent will seek permits or approvals, and to any parties specified in section 11.16 of the MEPA regulations. Per 301 CMR 11.16(5), the Proponent may circulate copies of the Single EIR to commenters in CD-ROM format or by directing commenters to a project website address. However, the Proponent must make a reasonable number of hard copies available to accommodate those without convenient access to a computer and distribute these upon request on a first-come, first-served basis. The Proponent should send correspondence accompanying the CD-ROM or website address indicating that hard copies are available upon request, noting relevant comment deadlines, and appropriate addresses for submission of comments. The Single EIR submitted to the MEPA office should include a digital copy of the complete document. A copy of the Single EIR should be made available for review at the Barnstable public library.[7]

RE: ENF Review. EOEEA 16148
BARNSTABLE. Comprehensive Waste Water Management Plan – Town Wide

Dear Secretary Theoharides,

The Southeast Regional Office of the Department of Environmental Protection (MassDEP) has reviewed the Environmental Notification Form (ENF) for the Comprehensive Waste Water Management Plan – Town Wide, Barnstable, Massachusetts (EOEEA 16148). The Project Proponent provides the following information for the Project:

Describe the proposed project and its programmatic and physical elements: ***The Project is a Town-wide Comprehensive Wastewater Management Plan which will expand wastewater infrastructure throughout the Town. The project is a thirty year plan, comprised of three, 10-year phases, predominantly focused on sewer expansion to achieve reduction in nutrients and address TMDL's in embayments, while also addressing water quality in ponds, drinking water source protection, targeted economic development and other wastewater needs of the community. The phases will be further broken up into individual projects, during which the Town anticipates that project specific permitting requirements (such as wetland resources, habitat, historical, etc.) will be reviewed in consultation with the appropriate agencies. The details of the plan are explained in extensive detail in the attached Comprehensive Wastewater Management Plan, specifically in Sections 5 and 6.***

Bureau of Water Resources Comments:
Wetlands and Waterways. The Wetlands and Waterways Program has reviewed the EENF for the Barnstable Comprehensive Wastewater Management Plan and offers the following comments.

Wetlands
The Project Proponent provides very little detail on the locations of the proposed facilities. It is therefore not possible for the Program to provide detailed comments on the potential Project

impacts on wetland resource areas, or the Projects ability to meet the regulatory performance standards and protect the interests of the Act.
However, the Program would like to comment on some of the information included in the EENF. The EENF indicates that the Project is not considered a Limited Project under the Wetlands Protection Act Regulations. The Project Proponent may wish to review 310 CMR 10.24(7)(b) regarding the Limited Project status of the proposed activities. Additionally, portions of the Project may meet the regulatory requirements to be considered a Minor Exempt Activity. The Project Proponent should review 310 CMR 10.02(2)(b) 1. & 2.j. prior to preparing and submitting any Notices of Intent.

Waterways.
The CWMP primarily focuses on future sewer system expansion, upgrading the wastewater treatment facility, water quality improvements and a variety of non-traditional nitrogen management methods. The ENNF does not provide information on which components of these future Projects will be constructed within area subject to Chapter 91 jurisdiction. Proposed sewer lines which cross over or under tidelands or tidal rivers and streams will likely require a Chapter 91 License. The conceptual non-traditional nitrogen management methods which include targeted dredging, cranberry bog conversion and bivalve aquaculture will also likely require Chapter 91 permitting. The Waterways Program recommends that the EIR include information on which future Projects of the CWMP are located in Chapter 91 jurisdictional areas.

Wastewater Management. MassDEP's Southeast Regional Office is pleased to have the opportunity to comment on the Town of Barnstable's Draft Comprehensive Wastewater Management Plan and Expanded Environmental Notification Form (EENF). MassDEP commends the Town on its efforts to restore the coastal embayments impacted by nutrient enrichment with an accelerated timeline.

Introduction
The Town has submitted an Expanded Environmental Notification Form for the Town's Draft Comprehensive Wastewater Management Plan (DCWMP). The DCWMP provides a summary of the evaluations and activities the Town has completed since 2003, the 2011 needs assessment report, and the activities anticipated through 2050. The Town plans to utilize a variety of strategies including sewering, wetland restoration, innovative alternative septic systems (I/A Systems), permeable reactive barriers (PRBs), and aquaculture to achieve nitrogen reduction targets necessary to meet the Total Maximum Daily Load (TMDL) in each of the watersheds linked to an identified impaired embayment. At the same time, the planning efforts account for wastewater needs other than nitrogen mitigation.

The EENF/DCWMP states that the Town plans to address the various wastewater needs of the community in a 30-year plan (3 phases of ten years). The Town also has parallel 3-stage sewer expansion plan to address needs in the Popponesset Bay Watershed and the Cotuit Bay Subwatershed of the Three Bays Watershed. The timing and execution of the 3-stage plan is subject to a "westerly solution" involving the collaboration of multiple communities. The 30-year plan consists of primarily a conventional approach of sewer expansion, but the Town has designed the plan with the ability to integrate non-traditional Projects in the last phase based on demonstration Projects. Based on the results of the demonstration Project data, the Town will assess how the Town can modify the existing plan to implement traditional strategies with the incorporation of non-traditional approaches. The focus of non-traditional strategy application is within the Three Bays Watershed.

The Barnstable DCWMP provides a clear schedule toward resource restoration with allowances for adaptive management and economic development. MassDEP recognizes that this is a plan subject to modification based on partnerships with towns that share common watersheds and the advancement of nutrient management strategies and technologies. As such, MassDEP supports the Town of Barnstable's plan to submit a 2025 Adaptive Management Report as an update to the 2020 DCWMP and Notice of Project Change filings (NPCs) for future non-traditional Projects.

Wastewater Treatment

The Town has diligently maintained and improved the existing Barnstable Water Pollution Control Facility (BWPCF) and associated infrastructure and plans to do so through Phase 1 of the 30-year plan. The Town is planning to invest in maintenance and improvement of existing infrastructure, including pumping stations, collection system evaluation studies and to address infiltration and inflow. The Town is planning to upgrade and expand the facility's treatment capacity throughout Phase 1 with improvements to the reactor trains, modifications of the secondary clarifier and expansion of the aeration system. The goal is to reduce the annual effluent nitrogen concentration from 6 mg/l to 3 mg/l while accommodating the anticipated new flow from sewer expansion Projects. In Phase 1, Barnstable will also upgrade the solids handling facility in years 2 through 4; upgrade the headworks in years 3 through 8; and install additional emergency generators in years 4 and 5.

The proposed changes are consistent with demands that will be placed on the facility and all design issues will be addressed during plan and/or permitting review. The treatment facility and associated infrastructure are regulated under MassDEP's groundwater discharge permit GW# 021-1. The permit expires in November 2023. The permit states the following in Section D. Supplemental Conditions 10:

> "Simultaneously with the permit renewal application in 2023, the permittee shall submit and engineering report prepared by a registered professional engineer to the Department for its review and approval that outlines in sufficient detail what modification (if any) to the facility or other changes are required to insure that the facility can remain in compliance with its GWDP and other applicable requirements through the next 5 year permit term (year 2028) and beyond".

For the engineering report, rather than Projecting required upgrades through the next 5-year permit term, MassDEP advises the Town to include any identified upgrades and or modifications of the facility through Phase 1 in accordance with Barnstable's DCWMP. Depending on the timing of the design and permitting of critical upgrades or modifications that could expand discharge capacity, the Town should consider submission of a WP11 in lieu of a WP12 permit application. MassDEP can be flexible with the submission date of the permit renewal, within reason, to simplify permit renewal and potential plan approval reviews.

Wastewater Disposal

The DCWMP acknowledges limitations in wastewater recharge at the BWPCF. The Barnstable Water Pollution Control Facility (BWPCF) discharges all of its treated wastewater effluent to disposal sites at the treatment facility. As a result of a planning level analysis conducted in 2017, MassDEP conservatively lowered the disposal capacity in the groundwater discharge permit to allow time to study the disposal capacity and understand the potential downgradient hydrogeological impacts. The Town has retained a consultant to investigate and model the hydrogeological impacts of different discharge capacities at the facility. The current Project seeks to discover the actual maximum disposal volume that would cause issues; further define the issues,

locate the properties where the issues would be observed; and assess the gravity and extent of those defined issues in the identified locations. Initial modeling indicates that depth to groundwater in low lying areas is the limiting factor, and that capacity varies depending on the amount of recharge from precipitation over the preceding three months. The preliminary Project findings indicate that the estimated average annual recharge capacity of the BWPCF is 2 MGD when the depth to groundwater is less than 8 feet at a downgradient receptor. The DCWMP states that the annual average flow is not expected to reach 2 MGD until 2027.

With potential complications at 2 MGD, based on the current on-going study, MassDEP supports the Town's current plan to maintain flows below 2 MGD until the Town designs, permits and constructs the new disposal sites. The disposal limitation is a significant obstacle in Barnstable's wastewater plan. MassDEP considers it imperative that the Town's plan prioritize its stated intent to investigate and permit additional wastewater sites in parallel with the wastewater treatment upgrades planned Phase 1.

Opportunities for Regional Cooperation

The Town is investigating several opportunities for regional cooperation with neighboring towns. Many local studies have shown that economies of scale from a cost savings and sustainability perspective offer significant advantages to regional solutions. Barnstable shares several watersheds with neighboring communities and is investigating community partnerships with them. Barnstable retained the University of Massachusetts School for Marine Science and Technology (SMAST) to conduct a Massachusetts Estuaries Project (MEP) model run for TMDL compliance of the Lewis Bay Watershed using the proposed plans of the two towns (Barnstable and Yarmouth) sharing this watershed. The model indicates that the Towns will meet the TMDL if the Towns execute their proposed plans. Additionally, the Towns are discussing and have studied options centered on Barnstable providing treatment for Yarmouth's raw wastewater and Yarmouth providing disposal capacity for some of Barnstable's wastewater in addition to the treated effluent from Yarmouth's wastewater. MassDEP supports the potential partnership and believes that a Watershed Permit can organize the expectations the Towns have of each other to carry out proposed plans for the restoration of Lewis Bay.

The Town shares the Popponesset Bay Watershed with Sandwich and Mashpee. The Towns have executed an inter-municipal agreement (IMA) to establish a work group. The objective of the work group is to apply for a Watershed Permit, come to agreement on a formula for allocation of responsibilities and costs, establish a municipal fiscal agent lead, and "to provide assurance that each town will take affirmative steps toward water quality improvement". Barnstable believes there are water quality concerns in the Shoestring Bay Subwatershed of Popponesset Bay and the Cotuit Bay Subwatershed of the Three Bays Watershed that would not be addressed via nitrogen trading in the IMA. As aforementioned, a potential "westerly solution" would allow Barnstable to carry out the 3-stage sewer expansion plan addressing those concerns. Barnstable has also been participating in discussions with the Upper Cape Communities (Bourne, Falmouth Mashpee and Sandwich) in an effort to form an Upper Cape regional treatment and disposal solution at Joint Base Cape Cod (JBCC). Barnstable is also discussing alternative "western solutions" with different permutations of Upper Cape Community partnerships outside of utilizing the facility on JBCC. MassDEP supports the regional efforts of the Upper Cape Communities and Barnstable and will continue provide regulatory guidance.

Lastly, the Town has formed a collaborative relationship with the Barnstable Clean Water Coalition (BCWC), a 501 (c) (3) non-profit organization. The Town and BCWC are working towards assessment of non-traditional technologies in the Three Bays Watershed.

TMDL Compliance. The Town retained SMAST to conduct a MEP model run with updated land use and water use data which demonstrated that the 30-year plan, once executed, will meet all of the nutrient removal targets to achieve the TMDLs in all of the embayments that are primarily in Barnstable: Three Bays, Centerville River, Lewis Bay and Barnstable Harbor. Barnstable designed the DCWMP with solely traditional strategies; the Town will apply adaptive management if necessary to adjust the plan with non-traditional strategies in the future. The Town not only considered MEP nitrogen target thresholds for choosing sewer expansion areas, but also considered areas with traditional Title 5 concerns, pond protection needs, flood zone considerations and economic development. The Town's DCWMP has a detailed breakdown of the Phase 1 sewer expansion in Barnstable Harbor, Centerville, Lewis Bay, Hall Creek and Three Bays Watersheds, with the expectation to submit a similar detailed plan for Phase 2 with the 2025 adaptive management update.

The Town of Barnstable implemented its own fertilizer regulation and continually invests in stormwater upgrades. The Town believes fertilizer regulations and stormwater upgrades are difficult to quantify for nitrogen reduction purposes and have decided not to rely or include those efforts towards TMDL compliance. MassDEP supports the implementation of fertilizer regulations and stormwater upgrades, but agree that they are hard to quantify towards TMDL compliance. Additionally, Barnstable's fertilizer regulation appears to overall provide best management practices and performance standards rather than prohibit fertilizer use, making it even more difficult to quantify the actual reduction.

The Town should continue to work towards a "western solution" to address the respective needs of Popponesset Bay and the Three Bays embayments. The Town should continue to consider alternative partnerships and solutions to assure the Town meets the TMDLs and water quality needs in those embayments.

Lewis Bay
The Town plans to expand sewer collection through 1,081 parcels in the Lewis Bay Watershed. The BWPCF treats and discharges within the Lewis Bay watershed and the Town plans to decrease annual total nitrogen from 6 mg/l to 3 mg/l. As discussed in the Opportunities for Regional Cooperation section, the Town is collaborating with Yarmouth on wastewater solutions for the shared embayment; however, the CWMPs for each Town anticipate meeting the TMDL on their own should a partnership not develop.

Centerville River
The Town plans to expand sewer collection through 55% of the watershed's parcels. The watershed septic reduction equivalency of the Centerville River Watershed sewer expansion will exceed the MEP nitrogen reduction target. The Town plans to execute the majority of this sewering in Phase 1.

Three Bays
The Town plans to expand sewer collection into 66% of the watershed's parcels. The watershed septic reduction equivalency of the Three Bays Watershed sewer expansion will not meet the MEP nitrogen reduction target. The Town is proposing several non-traditional demonstration Projects in the watershed with a focus of a reduction of the nitrogen load to the Marston's Mills River. The DCWMP includes six (6) non-traditional demonstration initiatives: Cranberry Bog Restoration Project, Mill Pond Dredging Project, Warren's Cove Dredging and Aquaculture Project, Sampson's Island Dredging Project, Horse Farm Permeable Reactive Barrier (PRB) Project, and the Innovative Alternative Technologies (I/A Systems) Project. With the exception of Sampson's Island Dredging

Project, all non-traditional initiatives are in the feasibility and Project design stage. The DCWMP acknowledges that the conventional approach does not meet the target nitrogen reduction (even accounting for Sandwich's portion of the load). The DCWMP states that the remaining load can be addressed through these non-traditional approaches; however, there should be a conventional contingency plan provided in the event that the non-traditional approaches do not produce the desired results.

The BCWC is assisting the Town with the Cranberry Bog Restoration Project, I/A Systems Project, and the Horse Farm PRB Project. The BCWC is currently working with the cranberry bog farmers to frame a demonstration Project that would restore wetlands in certain areas of the bogs for enhanced nitrogen attenuation without adversely affecting the ability to farm the bogs. Based on an SMAST study, the Town believes that a dredging Project would increase the residence time of an on-site pond, which would improve nitrogen attenuation. The Town would like to dredge Warren's Cove back to its sandy layer. Hypothetically, this may remove the nitrogen contribution from the decayed benthic layer and create and environment for local aquaculture, leading to enhanced nitrogen removal. The Cranberry Bog Restoration Project, Mill Pond Dredging Project and Warren's Cove Dredging Project are ecological restoration Projects with potential water quality benefits. The Projects have several benefits with respect to different aquatic species and public health and safety. As such, the Town should assure to gain permitting approval from all applicable regulatory agencies. As the Town moves from planning to permitting, the Town should work with MassDEP to form a water quality-monitoring plan and discuss the sustainability of the proposed water quality effects. Adequate monitoring data before and after the implementation of theses interventions facilitates the assessment of potential enhanced nitrogen attenuation and water quality benefits. At the minimum, monitoring plans should consider use of nearby monitoring station locations used for the MEP, utilized an adequate number of upgradient and downgradient monitoring stations to capture the effect of the intervention, and the testing of the same parameters used in the MEP according to the existing MEP Quality Assurance Project Plan (QAPP).

The Sampson's Island Dredging Project is a three-phase, three-year ecological restoration Project that will widen the channel width by approximately 400 feet to improve flushing and navigation in Cotuit Bay. The Town plans to complete the Project in winter 2020. MassDEP will consider monitoring data taken before the start of the intervention conducted incongruent with MEP standards. The Town should develop a monitoring plan for MassDEP approval to estimate the nitrogen attenuation impact of the Project moving forward.

Barnstable and BCWC are in the planning and feasibility stage for a PRB demonstration Project to investigate the interception of groundwater from a horse farm that contributes high loads of nitrogen during rainfall events. The DCWMP did not mention aboveground stormwater management in the description of this Project; as the Project is formed, aboveground stormwater management should be considered in an effort to capture nitrogen loads from the farm above and below the ground surface. BCWC is also collaborating with the Massachusetts Alternative Septic System Test Center (MASSTC) to create a demonstration Project to install and monitor I/A systems in a residential neighborhood. BCWC has teamed with the Nature Conservancy in this effort to develop a financing plan in creating a roadmap for widespread replacement of standard Title 5 septic systems with I/A septic systems. MassDEP will continue to work with BCWC and the Town as the demonstration Project continues to take form. All demonstration Projects involving I/A systems without general approval must coordinate with MassDEP's I/A program as part of the MassDEP I/A approval process. As the Town, BCWC, and the Nature Conservancy develop a financing plan, the Project team should factor in that the MassDEP expects any I/A initiative for

TMDL compliance and nitrogen reduction to be municipally managed. This will help assure that maintenance and required monitoring meets an acceptable quality standard.

Barnstable Harbor

Barnstable Harbor does not have a TMDL. The embayment has assimilative capacity for nitrogen with the exception of the Millway Subwatershed. The Draft MEP report indicates a 65% (4.7 kg/day-N) reduction in septic load for the Millway Subwatershed. The Town is planning to expand sewers into 370 parcels within the Millway Subwatershed. The watershed septic reduction equivalency of the Millway Subwatershed sewer expansion will exceed the MEP nitrogen reduction target.

Halls Creek Watershed

Halls Creek was evaluated as part of the Lewis Bay MEP report and TMDL. The MEP model shows the Halls Creek embayment system to have assimilative capacity for nitrogen. The Town plans to sewer a residential neighborhood located in the southwestern corner of the watershed to address pond protection considerations, water supply protection considerations, flood zone considerations, and economic development needs. The Town has already installed sewers in the uppermost section of the watershed.

Rushy Marsh Pond

Rushy Marsh Pond has a relatively low nitrogen load from its watershed. The watershed is small and has a large percentage of undeveloped area. According to the 2006 MEP report, its nitrogen enrichment may not be anthropogenic, but rather caused by the very low tidal exchange rate as the barrier beach restricts the inlet to Nantucket Sound. In 2012, the Town attempted to implement inlet widening to promote better flushing with a 10-foot wide box culvert in the southern portion of the basin, but the inlet did not maintain its width. Due to the tidal prism and the rate of littoral sand transport along the beach, a stable inlet is not feasible without extensive maintenance and hard structures such as jetties or extended pipe within the surf zone. MassDEP supports the Town's plan to focus restoration efforts towards other watersheds.

Popponesset Bay

As discussed in the Opportunities for Regional Cooperation section, the Town has an IMA with Mashpee and Sandwich to develop methodologies, strategies, and further agreements on nitrogen trading and monitoring responsibilities. The DCWMP relies on the formation of a "western solution" to address water quality and nitrogen reduction needs for the watershed. MassDEP will look to the 2025 Adaptive Management Report for a refinement of the plan for Popponesset Bay.

Adaptive Management

MassDEP views adaptive management as a certain amount of flexibility to recognize alternative approaches that allow for mid-course corrections in the implementation of a recommended plan. The Barnstable DCWMP is a plan Projected to meet TMDL compliance and the reliance on adaptive management is solely for the refinement of the existing plan amidst several variables that exist today. The Town plans to submit a 2025 Adaptive Management Report. MassDEP will look towards that report for further explanation of the plan for Phase 2 sewering, an update on non-traditional demonstration Projects, an update on disposal capacity expansion, and either materialization of a "western solution" or refinement of the plan for the Shoestring Bay Subwatershed of Popponesset Bay and the Cotuit Bay Subwatershed of the Three Bays Watershed.

Conclusion

The Barnstable DCWMP is a well-defined step forward. MassDEP commends Barnstable's efforts in addressing the Town's nitrogen management in a phased approach focusing not only on nutrient reduction but economic development, water supply protection, coastal resilience, and pond protection. MassDEP recognizes the effort of the Town to maintain existing infrastructure while expanding. MassDEP is supports the Town's approach to combine traditional approaches while engaging in demonstration Projects for non-traditional approaches and observing their effectiveness.

As the Town is aware, the disposal capacity limitation is a potential impediment to the Town's progress. MassDEP looks forward to the completion of the study of the existing disposal beds and the permitting and construction of new disposal sites. MassDEP will continue to provide regulatory guidance during the process. MassDEP recognizes that the DCWMP is clearly the result of hard work and thoughtful deliberation. Furthermore, MassDEP believes that the DCWMP will serve as the basis of a sound and innovative plan that will accommodate both the needs of the Town and MassDEP. MassDEP looks forward to working cooperatively with Barnstable, as both parties have in numerous past occasions, in order to achieve the goal of habitat restoration that we both ardently desire.

Miscellaneous Comments/Edits:

1. Table 2-3 indicates that Threshold TN Concentrations for the Barnstable Harbor Sentinel Station is "To Be Determined". The MEP Report indicates that the threshold concentration is the average of the bioactive nitrogen concentrations at Stations BM-11, BM-13, and BSH-4 and is set a 0.16 mg/L. The additional sentinel station in the Millway (as shown in Figure VIII-3 of the MEP Report) has a threshold concentration of 0.21 mg/L.

2. In Section 2.2.1.2, it mentions that the 208 Plan Update identifies stormwater contributing 23% of the controllable nitrogen load to the Three Bays watershed. This is a significantly higher figure than identified in the MEP report for this watershed. The difference in the numbers should be explained or reconciled.

3. In general, the discussion about stormwater should discuss how stormwater improvements, particularly in leaching catch basins, may or may not treat for total nitrogen.

4. The Town should consult with MassDEP's Air Quality section to determine if there are any permitting requirements for the proposed replacement and additional generators.

5. On Page 2-23 there is a typographical error in the last line of the first paragraph stating "Error! Reference Source not found".

6. On Figure 2-12: Nitrogen Hot Spots, most of the Town is not color coded. Perhaps this figure could be better described.

7. In Section 5.2.1.1.1 Nutrient Removal, the reference should be to Appendix QQ.

8. In Table 5-5, is there an update on the status of Mary Dunn, Campground and Aunt Betty's Ponds?

Bureau of Waste Site Cleanup Comments:

EENF #16148 – Based upon the information provided, the Bureau of Waste Site Cleanup (BWSC) searched its databases for disposal sites and release notifications that have occurred at or might impact the proposed Project area. A disposal site is a location where there has been a release to the environment of oil and/or hazardous material that is regulated under M.G.L. c. 21E, and the Massachusetts Contingency Plan [MCP – 310 CMR 40.0000].

The proposed Comprehensive Wastewater Management Plan is a three-phase Project spanning thirty years. There are many MCP sites located near and possibly within the proposed Project areas. Some of these sites have been closed, but other sites require on-going response actions and reporting until final closure under the MCP. A list of all MCP sites will not be presented here. Interested parties may view a map showing the location of BWSC disposal sites using the MassGIS data viewer (Oliver) at: http://maps.massgis.state.ma.us/map_ol/oliver.php Under "Available Data Layers" select "Regulated Areas", and then "DEP Tier Classified 21E Sites". MCP reports and the compliance status of specific disposal sites may be viewed using the BWSC Waste Sites/Reportable Release Lookup at: https://eeaonline.eea.state.ma.us/portal#!/search/wastesite

The Project Proponent is advised that if oil and/or hazardous material are identified during the implementation of this Project, notification pursuant to the Massachusetts Contingency Plan (310 CMR 40.0000) must be made to MassDEP, if necessary. A Licensed Site Professional (LSP) should be retained to determine if notification is required and, if need be, to render appropriate opinions. The LSP may evaluate whether risk reduction measures are necessary if contamination is present. The BWSC may be contacted for guidance if questions arise regarding cleanup.

Spills Prevention. A spills contingency plan addressing prevention and management of potential releases of oil and/or hazardous materials from pre- and post-construction activities should be presented to workers at the site and enforced. The plan should include but not be limited to, refueling of machinery, storage of fuels, and potential on-site activity releases. Information related to spills prevention best practices may be obtained at the following web page: https://www.mass.gov/files/spill_prevention.pdf?

Bureau of Air and Waste (BAW) Comments:

Air Quality. Construction and operation activities shall not cause or contribute to a condition of air pollution due to dust, odor or noise. To determine the appropriate requirements please refer to:

310 CMR 7.09 Dust, Odor, Construction, and Demolition
310 CMR 7.10 Noise

Construction-Related Measures

MassDEP requests that all non-road diesel equipment rated 50 horsepower or greater meet EPA's Tier 4 emission limits, which are the most stringent emission standards currently available for off-road engines. If a piece of equipment is not available in the Tier 4 configuration, then the Proponent should use construction equipment that has been retrofitted with appropriate emissions reduction equipment. Emission reduction equipment includes EPA-verified, CARB-verified, or MassDEP-approved diesel oxidation catalysts (DOCs) or Diesel Particulate Filters (DPFs). The Proponent should maintain a list of the engines, their emission tiers, and, if applicable, the best available control technology installed on each piece of equipment on file for Departmental review.

Massachusetts Idling Regulation
The ENF reports that the Project Proponent proposes simply to "minimize idling." MassDEP reminds the Proponent that unnecessary idling (i.e., in excess of five minutes), with limited exception, is not permitted during the construction and operations phase of the Project (Section 7.11 of **310 CMR 7.00**). With regard to construction period activity, typical methods of reducing idling include driver training, periodic inspections by site supervisors, and posting signage. In addition, to ensure compliance with this regulation once the Project is occupied, MassDEP requests that the Proponent install permanent signs limiting idling to five minutes or less on-site.

Climate Change Comments:
Climate Change – Greenhouse Gas Emissions**.** Pursuant to the Global Warming Solutions Act of 2008 (GWSA) (Chapter 298 of the Acts of 2008) and the Commonwealth's Clean Energy and Climate Plan the Commonwealth has established economy-wide greenhouse gas (GHG) emission reduction limits for Massachusetts that will achieve reductions of 25 percent below statewide 1990 GHG emission levels by 2020 and 80 percent below statewide 1990 GHG emission levels by 2050. Furthermore, Section 7 of the GWSA amended Section 61 of Chapter 30 of the Massachusetts General Laws by inserting, "in considering and issuing permits, licenses and other administrative approvals and decisions, the respective agency, department, board, commission or authority shall also consider reasonably foreseeable climate change impacts, including additional greenhouse gas emissions, and effects, such as predicted sea level rise."

The Proponent should consider potential GHG impacts (e.g., energy demand, use of renewable energy sources, transportation modes, etc.) of its Project in the context of furthering the Commonwealth's goals and recommended GHG mitigation policies in the *Clean Energy and Climate Plan for 2020*. Additional information on the Commonwealth's efforts to reduce GHG emissions can be found at: http://www.mass.gov/eea/air-water-climate-change/climate-change/massachusetts-global-warming-solutions-act/.

Sea Level Rise. The Project's location will subject it to the impacts of climate change-induced sea level rise. MassDEP recommends that the Proponent consider various scenarios and future conditions that are beyond the scope of the 100-year flood elevations designated in the Flood Insurance Rate Maps (FIRMs) to evaluate impacts such as sea level rise, shoreline change, and hurricane inundation. Recognizing the vulnerability of the coastline in the vicinity of the proposed Project site, the Proponent should be prepared to address the impacts of sea level rise and damage to property, businesses, and infrastructure over the lifespan of the Project. The potential risks to the Project should be evaluated based on sea level rise scenarios developed by known authorities, including the Massachusetts Coastal Zone Management Agency or community/localized studies.

One recommended resource is the Massachusetts Sea Level Rise and Coastal Flooding Viewer https://www.mass.gov/service-details/massachusetts-sea-level-rise-and-coastal-flooding-viewer. Please note that the viewer doesn't include all types of wastewater treatment and drinking water infrastructure.

Adaptation strategies should be considered to accommodate the effects of sea level rise and manage risk. Adding pre-disaster adaptation and post-disaster recovery measures will improve the Project resiliency to flooding and the impacts of extreme storm events. Please be aware that the Sea Level Rise and Coastal Flooding Viewer does not account for storm surge, waves, erosion and other dynamic factors, while FIRMs do not account for sea level rise, shoreline erosion, changes in the frequency and magnitude of storm events, etc. Therefore, it's important to review and consider

these combined with hurricane surge scenarios (which use current sea level) in order to plan for worst case scenarios and appropriate adaptation measures.

Climate Change – Adaptation. Section 7 of the Global Warming Solutions Act of 2008 (GWSA) (Chapter 298 of the Acts of 2008), amended Section 61 of Chapter 30 of the Massachusetts General Laws by inserting, "in considering and issuing permits, licenses and other administrative approvals and decisions, the respective agency, department, board, commission or authority shall also consider reasonably foreseeable climate change impacts, including additional greenhouse gas emissions, and effects, such as predicted sea level rise."

MassDEP recommends that the Proponent review and consider the data and recommendations identified in the 2011 Massachusetts Climate Change Adaptation Report issued by the Executive Office of Energy and Environmental Affairs (EEA) (http://www.mass.gov/eea/docs/eea/energy/cca/eea-climate-adaptation-report.pdf), the 2014 National Climate Assessment, specifically the Northeast region section, (https://nca2014.globalchange.gov/) and the 2017 U.S. Global Change Research Program Climate Science Special Report (https://science2017.globalchange.gov/) to address potential climate change impacts and adaptation measures feasible for implementation on the Project site. MassDEP also recommends that you check the following link for updates to the Massachusetts State Hazard Mitigation and Climate Adaptation Plan (https://resilientma.com/updates/) which is anticipated to be finalized in 2018. Once completed, this plan will include more usable data and information.

Wastewater & Drinking Water Treatment Facilities and Climate Change. The Proponent should consider the potential impacts of climate change as part of the planning, design and operation of the proposed expansion of the Headworks Facilities and upgrade of the WWTF. Wastewater treatment plants are among the largest energy consumers in many cities and towns across Massachusetts.

Therefore, minimizing the life-cycle operational costs and associated greenhouse gas emissions will have long-term economic and environmental benefits for the community and the Commonwealth.

MassDEP suggests review of the following resources, as well as any other governmental, industry, or research institute reports to identify GHG and energy reduction strategies, and climate resilience and adaptation measures that the Proponent, as feasible, should commit to implement or continue to explore upon completion of the MEPA review. The resources listed below under Implementation also include potential funding sources.

Proposed s.61 Findings

The "Certificate of the Secretary of Energy and Environmental Affairs on the Environmental Notification Form" may indicate that this Project requires further MEPA review and the preparation of an Environmental Impact Report. Pursuant to MEPA Regulations 301 CMR 11.12(5)(d), the Proponent will prepare Proposed Section 61 Findings to be included in the EIR in a separate chapter updating and summarizing proposed mitigation measures. In accordance with 301 CMR 11.07(6)(k), this chapter should also include separate updated draft Section 61 Findings for each State agency that will issue permits for the Project. The draft Section 61 Findings should contain clear commitments to implement mitigation measures, estimate the individual costs of each proposed measure, identify the parties responsible for implementation, and contain a schedule for implementation.

Other Comments/Guidance

The MassDEP Southeast Regional Office appreciates the opportunity to comment on this EENF. If you have any questions regarding these comments, please contact Jonathan Hobill at (508) 946-2870.

Very truly yours,

Project Name:	*Comprehensive Wastewater Management Plan*
Proponent:	*Town of Barnstable*
Location:	*Town-Wide*
Document Reviewed:	*Environmental Notification Form*
EEA No.:	*16148*
NHESP No.:	*12-30930*

Dear Secretary Theoharides:

The Natural Heritage & Endangered Species Program of the Massachusetts Division of Fisheries & Wildlife (the "Division") has reviewed the *Environmental Notification Form* (dated January 2020) for the Town of Barnstable's Comprehensive Wastewater Management Plan (CWMP; the Project) and would like to offer the following comments regarding state-listed species and their habitats.

The Town of Barnstable's ponds, bays and estuarine waters provide critical foraging, breeding, migration and over-wintering habitats for a suite of state-listed rare species. We commend the Town for its efforts to improve water quality within these critical habitats, and for its consideration of both traditional and non-traditional approaches to wastewater and nutrient management.

Portions of Barnstable are mapped as Priority Habitat for state-listed rare species. All projects proposed within Priority Habitat, which are not otherwise exempt from review pursuant to 321 CMR 10.14, require review through a direct filing with the Division pursuant to the Massachusetts Endangered Species Act (M.G.L. c. 131A) and its implementing regulations (MESA; 321 CMR 10.00). The MESA is administered by the Division and prohibits the Take of state-listed species, which is defined as "in reference to animals…harm…kill…disrupt the nesting, breeding, feeding or migratory activity…and in reference to plants…collect, pick, kill, transplant, cut or process…Disruption of nesting, breeding, feeding, or migratory activity may result from, but is not limited to, the modification, degradation, or destruction of Habitat" of state-listed species (321 CMR 10.02).

To the extent possible, the Division has evaluated and provided comments below on the recommended Phase 1 actions outlined within the ENF (Sections 5.1.2 and 5.2.4.2). For many of the proposed actions,

the Division has not yet received a direct filing pursuant to the MESA; therefore, the comments provided below should be considered preliminary in nature.

Construction of New Sewer Infrastructure

The Division notes that wastewater collection systems proposed within Priority Habitat may be exempt from MESA review pursuant to 321 CMR 10.14 (6) and or (10), which state that "[t]he following Projects and Activities shall be exempt from the requirements of 321 CMR 10.18 through 10.23…"

> *[6] construction, repair, replacement or maintenance of septic systems, private sewage treatment facilities, utility lines, sewer lines, or residential water supply wells within existing paved areas and lawfully developed and maintained lawns or landscaped areas, provided there is no expansion of such existing paved, lawn and landscaped areas;*
>
> *[10] installation, repair, replacement, and maintenance of utility lines (gas, water, sewer, phone, electrical) for which all associated work is within ten feet from the edge of existing paved roads…;*

The complete list of MESA filing exemptions may be found on the Division's website. We would encourage the Town to examine design alternatives which avoid and minimize impacts to Priority Habitat, including re-use of existing paved, developed and or landscaped areas wherever possible. For any proposed work within Priority Habitat, the Town should proactively consult with the Division to confirm whether proposed work is exempt from MESA review or will require review through a direct filing with the Division.

Modifications to Existing Barnstable Water Pollution Control Facility (BWPCF)

The Division notes that the Town's existing wastewater treatment facility does not appear to be located within the Priority Habitat of state-listed rare species, as indicated in the Massachusetts Natural Heritage Atlas (14th Edition). Therefore, the Division anticipates that any proposed upgrades to the BWPCF would not require review for compliance with the MESA.

New Discharge Site

The ENF states that a new effluent disposal site(s) will need to be identified, permitted and constructed to accommodate flows from proposed sewer areas. As provided above, any new effluent disposal site(s) proposed within Priority Habitat would require review for compliance with the MESA. The Division encourages the Town to examine alternative locations for the proposed disposal site(s) that are located outside of, or that otherwise avoid and minimize disturbance within, Priority Habitat. For any proposed work within Priority Habitat, the Division would encourage the Town to contact the Division in advance of a formal filing to proactively address any rare species concerns and discuss potential MESA permitting pathways.

Joint Base Cape Cod

The ENF states that Barnstable, Bourne, Falmouth, Mashpee and Sandwich are conducting a regional evaluation of wastewater discharge options on Joint Base Cape Cod (JBCC). Specifically, the ENF also states that the Towns are discussing the possibility of utilizing the existing wastewater treatment facility at JBCC – which currently consists of a treatment plant and four infiltration basins northwest near the Cape Cod Canal – as a regional facility.

The Division notes that, with the exception of the treatment plant itself, the existing JBCC wastewater treatment facilities and their surrounds appear to be located within Priority Habitat. Any proposed upgrades to or expansions of these facilities would require review by the Division for compliance with the MESA.

In addition, the Division notes that the four existing infiltration basins at JBCC near the Cape Cod Canal are located within the Camp Edwards Wildlife Management Area. Chapter 47 of the Acts of 2002 transferred the care, custody and control of the northern 15,000 acres of JBCC to the Division as the Camp Edwards Wildlife Management Area to conserve fish and wildlife resources for the benefit of the citizens of the Commonwealth. Any proposed projects or activities within the Camp Edwards Wildlife Management Area, including but not limited to any potential upgrades to or expansion of existing wastewater treatment facilities, would require review and approval by the Division.

The Town should contact the Division as soon as possible to discuss this proposal. In advance, we request that the Town provide more detailed information about this proposal to the Division for review, including but not limited to whether it would include upgrades to or expansion of existing JBCC effluent disposal facilities. In advance, we request that the Towns evaluate alternative locations for this proposal that avoid and minimize work within Priority Habitat.

Cotuit Cut / Sampson's Island Dredging

The Division reviewed and determined (October 6, 2009) that this project, as proposed, would not result in a Take of state-listed species. Therefore, the Division has no additional comments on this project at this time.

Non-Traditional Approaches for Marstons Mills River System: Mill Pond Dredging

The ENF states that the Town will pursue dredging of Mill Pond as a component of its non-traditional approaches to nutrient management. The Division notes that Mill Pond is mapped as Priority Habitat for a state-listed fish species. Based on a review of information submitted to the Division to date and information currently contained in our database, the Division anticipates that this project, as proposed, **will likely result in a Take (321 CMR 10.18 (2)(b))** of state-listed species. Projects resulting in a Take of state-listed species may only be permitted if they meet the performance standards for a Conservation and Management Permit (CMP; 321 CMR 10.23). In order for a project to qualify for a CMP, the applicant must demonstrate that the project has avoided, minimized and mitigated impacts to state-listed species consistent with the following performance standards: (a) adequately assess alternatives to both temporary and permanent impacts to the state-listed species; (b) demonstrate that an insignificant portion of the local population will be impacted; and (c) develop and agree to carry out a conservation and management plan that provides a long-term net benefit to the conservation of the state-listed species.

The Town has been consulting with the Division to proactively address state-listed species concerns and MESA permitting associated with this project. Coordination and consultation with the Division remain ongoing at this time. As the MESA review process for this project remains ongoing, no work or activities associated with this project may occur until the Division has made a final decision relative to the CMP.

We appreciate the opportunity to comment on this project. If you have any questions about components of this letter related to MESA, please contact Jesse Leddick, Chief of Regulatory Review, at jesse.leddick@mass.gov or 508-389-6386. If you have any questions about the components of this letter

related to the Camp Edwards Wildlife Management Area, please contact Jason Zimmer, Southeast District Manager, at jason.zimmer@mass.gov or 508-759-3406. We look forward to working with the Town to address the comments provided herein and further its efforts to improve water quality in the Town of Barnstable's ponds, bays and estuarine waters.

Sincerely,

Everose Schlüter, Ph.D.

MEMORANDUM

TO: David Mohler, Executive Director
Office of Transportation Planning

FROM: J. Lionel Lucien, P.E, Manager
Public/Private Development Unit

DATE: March 27, 2020

RE: Barnstable Comprehensive Wastewater Management Plan – EENF
(EEA #16148)

The Public/Private Development Unit (PPDU) has reviewed the Expanded Environmental Notification Form (EENF) for the Barnstable Comprehensive Wastewater Management Plan in Barnstable. The town-wide sewer expansion project consists of adding 190 miles of new sewer main and several above-ground pump station structures.

The project will require a Non-Vehicular Access Permit from MassDOT. The new sewer lines will run along and cross state highways Route 132 and Route 28, and the state jurisdictional portions of Route 6A and Phinney's Lane. Though the new sewer lines will not generate traffic, temporary traffic impacts related to the construction of the project may occur. Accordingly, the proponent should develop a Traffic Management Plan (TMP) to be reviewed and approved by MassDOT. The proponent may also wish to adopt a Temporary Traffic Control Plan (TTCP), to be developed consistent with FHWA and MassDOT guidelines.

MassDOT recommends that no further environmental review be required based on transportation issues. The details of the above and any other access-related issues can be addressed during the permitting process for the project. If you have any questions regarding these comments, please contact me at (857) 368-8862 or Nicholas Zavolas at (857) 368-8856.

Dear Secretary Theoharides:

The Division of Marine Fisheries (MA DMF) has reviewed the Notice of Project Change (NPC) for the Town of Bourne's Integrated Solid Waste Management Facility.
The project was reviewed with respect to potential impacts to marine fisheries resources and habitat.

Based on the information provided, MA DMF has no recommendation for sequencing, timing, or methods that would avoid or minimize impact at this time.

Questions regarding this review may be directed to John Logan in our New Bedford office at (508) 742-9722.

Re: Environmental Notification Form — EEA No. 16148 (CCC File No. 20037)
Barnstable Comprehensive Wastewater Management Plan

Dear Secretary Theoharides:

Thank you for the opportunity to comment on the above-referenced ENF.

Commission staff believe the ENF sufficiently details the scope of the Town's Plan and addresses the appropriate environmental issues that will be addressed through subsequent MEPA review. Further, staff support the Town's request for and the Secretary's grant of a Single EIR, as the ENF describes and analyzes a wide variety of alternatives, provides sufficient environmental baseline information, and includes planning and design to avoid environmental impacts. The overall purpose of the Plan is to protect or improve a variety of natural resources from environmental degradation: coastal waters, freshwater ponds and drinking water supplies.

The Cape Cod Commission reserves further substantive comment for later stages of MEPA review. Commission staff have consulted with and provided comments to the Town as the Town has developed the Plan. Ultimately, after MEPA review concludes, the Cape Cod Commission will review the Plan to determine its consistency with the Section 208 Area-wide Water Quality Plan for Cape Cod.

Commission staff are available to discuss any questions you might have about these comments.

Sincerely,

Kristy Senatori
